"Fundamental Equations for Press Fits" published in the "Engineering News" Mar. 17, 1910. "Formulas for Forced and Shrunk Fits" published in the "American Machinist," Vol. 42, page 377. "Formulas and Alignment Charts for Taper Press Fits" published in the "American Machinist," Vol. 44, page 275. Note—The empirical formulas were derived from data corresponding to the full-line portion only of the curves shown

Radial and tangential stresses and forcing pressures are plotted against both ratios:

$$\frac{\textit{Outside diameter}}{\textit{Diameter of bore}} \quad \text{and} \quad \frac{\textit{Thickness of ring}}{\textit{Diameter of bore}}$$

The stresses are for a press fit of 0.001 in. per inch of diameter of bore, and the forcing pressures are for 0.001-in. force fit and the 1-in. length of fit. For any force fit J for a ring having an outside diameter D and a bore d find out to what fraction of 0.001 in. per inch of bore the given press fit coresponds and multiply the value of the stress obtained from the diagram for that fraction.

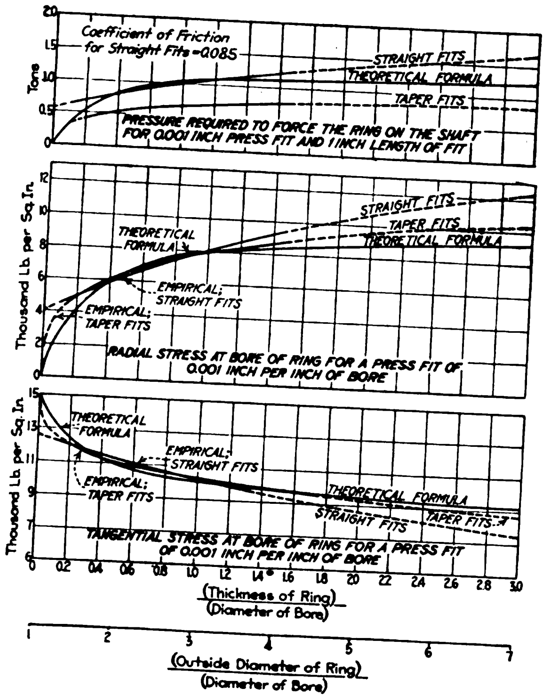

FIG. 2. CAST-IRON RING FORCED ON A CAST-IRON SHAFT

"Fundamental Equations for Press Fits" published in the "Engineering News," Mar. 17, 1910. "Formulas for Forced and Shrunk Fits" published in the "American Machinist," Vol. 42, page 377. "Formulas and Alignment Charts for Taper Press Fits" published in the "American Machinist," Vol. 44, page 275. Note—The empirical formulas were derived from data corresponding to the full-line portion only of the curves shown

The result will be the stress (tangential or radial) corresponding to the press fit J.

For example: If we have a cast-iron ring 13 in. outside diameter and 5-in. bore forced on a steel shaft with 0.003-in. force fit, we find from the diagram that for $\frac{D}{d} = \frac{13}{5} = 2.6$ the tangential stress for 0.001 in. per inch of bore (or 0.005 in. total) is 10,200 lb. per sq.in. (using the curve corresponding to the fundamental equation). In this case the force fit per inch of bore is $\frac{0.003}{5} = 0.0006$ in., which means that it is only 0.6

of 0.001 in. per inch of bore, and the corresponding stress will be 10,200 × 0.6 = 6,120 lb. per sq.in.

If we want to know what is the pressure to be used to force the ring on the shaft, we find that for 0.001-in. press fit and 1-in. length of fit we need to use 1 ton. In our case we have 0.003-in. force fit, and we shall need to use 3 tons for every inch of length of the fit (for every inch of width of the ring, independently of the length of the fitted surface that may be relieved at the center, always assuming that the ring is of practically a uniform section on all the width).

In the case of a taper fit, if h is the taper per inch of length and U is the relative axial displacement of the ring and the shaft, the total press fit will be Uh, and the press fit per inch of bore will be $\frac{Uh}{d}$. Proceed also in this case in the same way as before, but use the proper curve in the diagrams shown corresponding to the equations for taper fits.

Professor Jenkins' empirical formulas can be relied upon only between the limits found in the data that he investigated (between $\frac{D}{d} = 1.4$ and $\frac{D}{d} = 4$ for taper fits), and the corresponding portions of the curves are shown in full lines; the remaining portions of the curves are shown in dotted lines.

As I have stated before, there is no doubt that Professor Jenkins with his investigation has made a very useful contribution to the practical knowledge of forcing pressures that may be expected between certain limits and for a given class of work; but I believe that his empirical formulas are expressed in such a form that they cannot be relied upon for values of the variables outside of the limits of the experiments investigated, because the equations fail to satisfy the fundamental requirements of the dimensional theory, not having all the terms of the same dimensions, and so the formulas cannot be generally correct. This is a very undesirable feature for any empirical formula and may lead to serious errors when the limits inside which it may be used are not kept in mind.

If a ring having a bore d, a length L and a section A is forced on a shaft with a press fit J and the pressure used is P, these five quantities must be connected by some sort of relation, which may be symbolized by $F(d, L, A, J, P)$. Applying Buckingham theorem (see "Model Experiments and the Forms of Empirical Equations," by E. Buckingham, "Proceedings" of American Society of Mechanical Engineers, 1915) we find:

$$P = d^2 Y\left(\frac{A}{d^2}, \frac{J}{d}, \frac{l}{d}\right)$$

where Y is an unknown function which remains to be found from the experiments that Professor Jenkins has investigated. An equation of this form would undoubtedly be correct, because all the terms of the unknown function are independent and dimensionless, and we should not be led to the absurd results that we get when in the empirical formulas for straight fits (except for steel on steel) we put $d = D$.

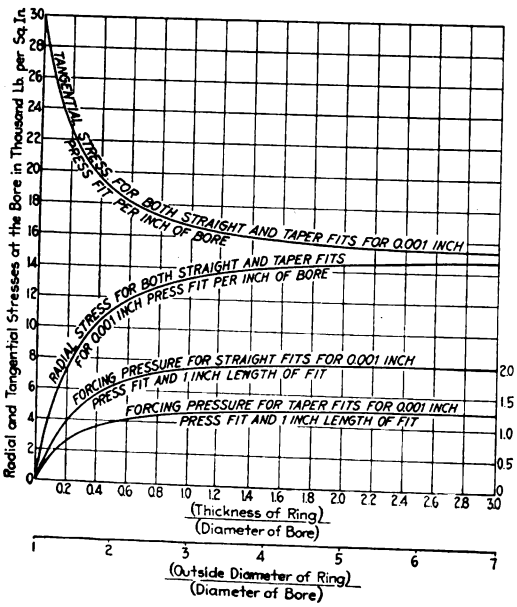

FIG. 3. STEEL RING FORCED ON A STEEL SHAFT

"Fundamental Equations for Press Fits" published in the "Engineering News," Mar. 17, 1910. "Formulas for Forced and Shrunk Fits" published in the "American Machinist," Vol. 42, page 377. "Formulas and Alignment Charts for Taper Press Fits" published in the "American Machinist," Vol. 44, page 275.

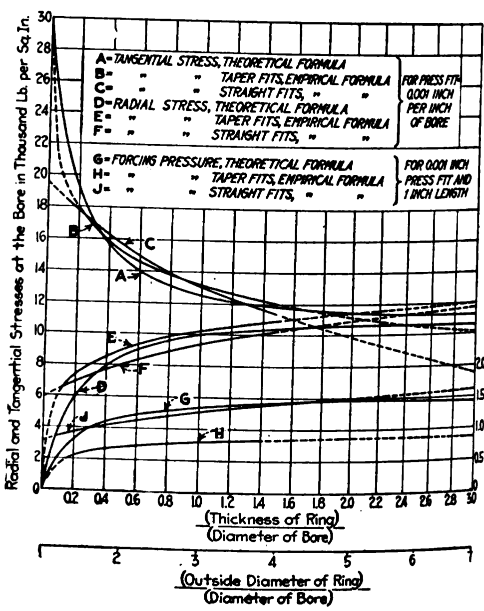

FIG. 4. STEEL RING FORCED ON A CAST-IRON SHAFT

"Fundamental Equations for Press Fits" published in the "Engineering News," Mar. 17, 1910. "Formulas for Forced and Shrunk Fits" published in the "American Machinist," Vol. 42, page 377. "Formulas and Alignment Charts for Taper Press Fits" published in the "American Machinist," Vol. 44, page 275.

Note—The empirical formulas were derived from data corresponding to the full-line portion only of the curves shown

I believe that, since Professor Jenkins has made such a thorough study of the problem of force fits and he has all the data from which he derived his empirical formulas, it would be an easy matter for him to rewrite his formulas in a way more consistent with the dimensional requirements of empirical formulas and more generally correct for any value of $\frac{D}{d}$, this being a step in the direction of logical analysis.

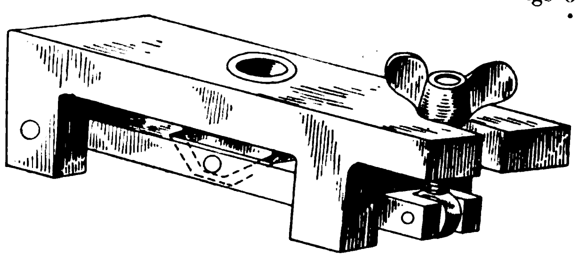
Best Way To Do Certain Things--A Leaf Jig

Speaking of the best way to do certain things, the jig and fixture field is certainly rich in opportunity. One case is the leaf type of jig. Since this design of jig is used in all sizes for many kinds of work, remarks on the subject will apply to the whole field. The best arrangement in this jig is to have the leaf support the work—in other words, drill against the leaf. The bushings should be placed in the frame of the jig and the work should be located there, thus accurately registering the work with the bushings.

The mistake often made in the design of these jigs is to place the bushings in the leaf of the jig and support the work in the frame. While it is possible to make such a jig give passable results on finished stock when conditions are favorable and the jig is carefully built and new, such a design is a failure when used on pieces like rough castings and drop forgings. Furthermore, if the size of the stock varies, the bushings will stand at an angle with the drills, and the drills are likely to break. Or in the case of larger holes, where considerable clearance is allowed in the bushings, either the bushings or



A LEAF TYPE OF JIG

the drill will be sadly chewed up. Also as the jig grows old and the pin bearing holes wear, lots of work will be spoiled.

The correct idea is shown in the illustration for the leaf type of jig. The part drilled is a flat piece, and it is necessary to use an equalizer in the leaf.

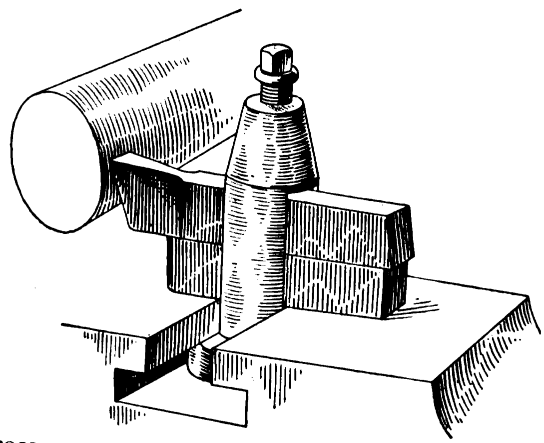
Bridgeport, Conn. W. Burr Bennett.

Cutting Off Steel in the Lathe

Replying to the article on page 294 by G. A. Remacle, I agree with him that the causes of chattering and digging in of the tool are not (in any case) the cause or fault of the lubricant. The tool rest illustrated does not promote chattering. To avoid it, the circular segment for the height of the tool adjustment should be removed, and plain flat packing, as long as possible, should be substituted, as here shown. This change will be found to rectify to some extent the lack of foresight of the lathe designer.

The article ends by saying, "And once the cut is started the tool should be fed in without stopping." This remark is of the greatest importance.

The height of the tool must be governed by the condition of the main bearings and the method of holding. If the job is held in the chuck with the center against one end, the trouble is increased. When the parting tool hits the work, the latter will rise exactly the amount of play in the main bearings and the chuck. If the tool is kept constantly cutting, the piece will stay up; but once the cut is allowed to ease off, the work will drop and chatter. Therefore, the tool should be set a trifle high,



TOOL ARRANGEMENT FOR REDUCING CHATTER IN CUTTING OFF STEEL IN THE LATHE

according to the requirements of the job and the intelligence of the operator.

Luton, England. Archibald Young.

Paying Pupils in the Public-School Machine Shop

The question of paying pupils in public-school machine shops has from time to time stirred the vocational schools in Massachusetts, and it is open to some discussion. The reasons for proposing this scheme are two, though they are to all intents and purposes one. While these schools are still new and it is hardly probable that the best methods of conducting them have been discovered, yet the number of boys who really finish their allotted time at the school is small compared with the number that enter.

In a majority of cases the reason for leaving is generally the fact that there is a position at fair wages open, or else the pinch of poverty at home makes it necessary to take the first job that offers. The result is the same in either case—Massachusetts has added another unskilled or semiskilled citizen to her ranks.

In comparison, with this condition as a basis, the corporation school presents a much better showing, and in searching for the reason the fact that the apprentices at these schools receive wages is considered by many to be the chief. While it may be the principal cause, still there are two other very important factors that may have a bearing on the case. One is that the group at the corporation school is selected, and the other is that they are older boys, 16 years of age at least. Because of these two things they stick better and progress more rapidly than if they were younger and no selection was made.

To overcome this difference in the length of attendance, it is proposed that the community supporting one of these schools be asked to pay the boys who attend a nominal sum, say $100 per year. It is believed that by doing this they will stimulate the boy to greater effort and at the same time enable him turn enough money into

the family exchequer to enable him to continue at the school and complete his course.

While I believe that the advocates of this scheme are honest in their intentions, still is seems to me that they have not considered the other side of the case. Some people still feel that it is not the duty of the public to support trade schools, thinking that the manufacturer is the only beneficiary of such training and therefore he should pay the expense of it. There are others who feel that the cost of vocational education is excessive and that too much of a burden is placed on the taxpayers. Imagine then the injured state of mind that these two classes of people would be in if it was seriously proposed to make such payment; and too, such action would fail of support from the very people who now favor it.

It would seem that we must have a very poor opportunity to offer our boys if, after providing everything free of charge, we have to go down into our pockets still farther and pay pupils to come and partake of the advantages. While on the face of it the idea seems absurd, I have heard so much talk of it that I should not be surprised to hear of someone actually trying to put such a plan through.

I can readily see that, if the sales account of any of these schools should exceed the maintenance charges, such money would be in excess of the amount the community had expended, and it would then be good policy to take this surplus and divide it among the boys who had earned it. But to pay them artificial wages would have a very pernicious effect, similar to that which free textbooks and supplies have had in framing the attitude this nation holds toward public property.

Westfield, Mass. BURTON A. PRINCE.

Small-Shop Apprenticeship

There seems to be much comment of late regarding the proper training of machinist apprentices. Many of the larger firms have originated and installed systems whereby the apprentice receives a standardized form of mechanical training and is given the opportunity to acquire enough technical knowledge to enable him to develop into a high-grade mechanic. This schooling is given at regular periods by skilled instructors who are held responsible for its success, and together with the shop training they receive, it must be very beneficial to the boys who are mechanically inclined.

But how about the boy who undertakes to learn his trade in the average small shop? What encouragement does the average small-shop owner give his apprentice? How many of them will endeavor to teach him something about shop mathematics, for instance? The average small-shop owner will not teach a boy any more than is absolutely necessary for him to know in order to perform the work on hand. It is true that the boy will generally have a greater variety of work to do in the small shop, and most small-shop owners believe that this opportunity should be sufficient inducement to make a boy select such an apprenticeship in preference to one in a large plant. Although he will receive a greater variety of work to perform, the supervision of his mechanical training is usually left to a busy foreman who is too interested in production to devote much time to the training of apprentices and will leave it to the mercy of fellow-employees who may take an interest in the boys. We all know that the average small-shop owner cannot afford such apprenticeship schooling as some of the larger plants are installing. However, he should endeavor to teach the boy whose previous schooling has been cut short enough shop mathematics to enable him to develop into a first-class machinist capable of working in any line of the business. I have seen many young machinists who had served their apprenticeships in small shops and were really good workmen, but could not make ordinary change-gear calculations. Although any of them could read a micrometer, nine out of ten could not change fractions to decimals without the aid of a decimal-equivalent chart. The ambitious boy who has the ladder-climbing spirit and finds himself in such a predicament at the end of his apprenticeship is not yet prepared for his climb and must make way for the boy who has acquired during his apprenticeship a knowledge of shop mathematics and the self-confidence that accompanies this knowledge.

However, the question as to whether a boy should select the large plant with its apprenticeship-schooling system or a small one with its greater variety of work to offer is a rather knotty problem to answer. Much depends on the boy's present education, his future plans and the intended employer's record as a developer of machinist apprentices. The boy should know what percentage of the employer's apprentices have turned out successful mechanics and how much of their mechanical training was acquired during the apprenticeship.

Although such records would be hard to keep, the boy who is selecting the foundation place of his career should know whether he is going to exchange his services merely for the profit of the employer or whether the employer is going to give him the knowledge and training agreed upon.

South Bend, Ind. A. J. CHAMBERLAIN.

Who Can Make This Nail?

On page 604 F. P. Ronnan asks who can make a special nail. Unless he has given detailed information about the kind and quality of metal, whether the corners must be sharp, whether the diameters and length of shoulder must be kept within close limits, whether the exact length over all and all dimensions must be closely adhered to or otherwise—it is small wonder that he has received no bid for the job.

At first glance it looked to me like an easy task to design tools to make this nail, but when I began considering its probable use and the essential requirements, I was at a loss to know where to begin. From past experience in upsetting and forming bar iron I believe the nail can be made commercially in upsetting dies.

Rochester, Minn. GEORGE G. LITTLE.

Glass-Cutting Experience

In reply to the letter by George G. Little, on page 516, detailing his experience in cutting glass plates, I wish to say that it is impossible to cut glass with a diamond that has an artificial or ground and polished point or cutting edge. The only type of diamond that will cut glass is a stone having natural points or cutting edges. A diamond with ground and polished edges or facets will scratch glass, but will not cut it.

New York City. THOMAS L. DICKINSON.

Industrial Preparedness From the Engineer's Viewpoint

SYMPOSIUM OF DISCUSSION

SYNOPSIS—Many points of view were brought out at the New Orleans meeting of the American Society of Mechanical Engineers in the discussion of the paper dealing with the timely subject of organizing for industrial preparedness. Abstracts of the most important discussions are presented.

A Unique Opportunity for Engineering Endeavor

TELEGRAM BY H. E. COFFIN

I am sorry not to be able to take part in the discussion of Mr. Miller's paper, that I might in person help to bring home to every man at the New Orleans meeting the obligation and at the same time the great opportunity resting with him as a member of the American Society of Mechanical Engineers. In this paper, you have before you in brief outline the main features of a patriotic national engineering endeavor unique in this world's history.

We as engineers and chemists had harnessed the resources of this country for the people's service, and now at the direct request of the President of the United States we are asked to make a careful inventory of these resources for the use of our defensive line. A successful performance of this great task, to which the governing bodies of our technical societies have pledged us, cannot but bring the American engineer enhanced reputation and closer future relations with the national Government.

Organization of Volunteer Industrial Associations

BY H. E. HARRIS

The program for preparedness, as it affects the engineering profession and industrial America as a whole, is well thought out and should be supported by every engineer and manufacturer. However, there is one point of vast importance which could stand considerable emphasis, and that is the outlined plan for organizing an Industrial Reserve.

It is not only necessary to enlist the engineers and the manufacturers, but it is necessary also to get the loyal support of every man who is a skilled workman and who is necessary to this country as such. Let these skilled employees know more about the plans of the industrial-preparedness program, enlist their sympathies and obtain their pledge of willingness to be depended upon in case of emergency. Make them feel that in case America is called upon to defend herself that their interests and their employers' interests are in a common cause and that the employers and the men will stand shoulder to shoulder in such an emergency. Skilled workmen who are floaters and otherwise undependable are of no value as a part of the industrial bulwark of the nation and will hesitate to pledge themselves to the country's service in time of need; and it is well to know upon whom dependence may be placed to stand at their posts when called by their country and for employers to give to such as can be relied upon the responsible positions in their factory organizations.

It is up to employers who are patriotically inclined to reach the men by individual talks, meeting them on common ground and obtaining their views and their willingness to enlist as members of the Industrial Reserve, if called upon. In view of the present conditions of unrest it does not seem as though any time should be lost in making a coalition as far as possible between the employer and employee on a patriotic basis.

As an example of what may be done in this direction, this is what has been accomplished along these lines by the company with which I am connected: The men were invited to meet together; and at the meeting, abstracts from the paper written by Mr. Miller were read, a general discussion invited and an impromptu talk given to the men. This meeting took over an hour. Men who for various reasons had neglected to take out their naturalization papers were earnestly advised to do all they could to get on record as to their intentions. Men who had their first naturalization papers, but had not taken out their second, were also given similar advice; and every man was invited to join in forming an association which pledged them to put all other considerations aside in case of a call for the defense of the country and to pledge them to serve in its defense as members of the Industrial Reserve. Resolutions were passed as follows:

We the undersigned, do solemnly and patriotically pledge ourselves to the defense of the United States of America in case of war against any enemy whatsoever.

We have associated ourselves together as members of the Square Deal Industrial Volunteer Association, employees of the H. E. Harris Engineering Co., and as native and naturalized citizens of the United States of America and further voluntarily pledge ourselves to patriotically serve in the Industrial Reserve of the United States of America as skilled workers of the H. E. Harris Engineering Co., whenever called upon by the Government to do so, irrespective of our several religious, political beliefs, other associations, prior nationalities, antecedents or individual prejudices.

This pledge and agreement is binding upon the Square Deal Industrial Volunteer Association as a whole, but any member leaving the employ of the H. E. Harris Engineering Co. and being released from his membership in the foregoing association prior to the call of the United States Government is also automatically released from this pledge.

The men evinced a hearty interest, exhibited a large share of patriotism and demanded permission to sign at once, with the exception of one or two not skilled men who were desirous of joining either the navy or army in case of war. There were no restrictions made in regard to the men's prior nationality or whether they had obtained naturalization papers partly or completely. If any aliens wished to sign, they were allowed to do so after signifying their intentions of becoming citizens of the United States at their earliest opportunity.

The enthusiasm that this meeting created was rather more than was expected, and those men who were aliens got very busy the next day to see how soon they could get their citizenship papers.

So I am able to come here with the feeling that the men in my factory are 100 per cent. strong in patriotism and with the feeling that I could offer my country and the Naval Consulting Board the support and services of the company and its employees' support as a unit, without a dissatisfied or dissenting vote.

It is important to distribute information in a simple form to the engineers of the country, so that they may be in a position to help those who are desirous from reasons of loyalty to their adopted country to become full-fledged citizens, by giving the necessary information as to just what steps are to be taken.

Getting Our Money's Worth

BY F. J. MILLER

Engineers have always paid far more attention to efficient organization than has been paid to it by any others, and it seems to me that they might render their best possible service at this time by suggesting such improvements in organization as would result in getting more for the money and effort expended than is at present secured.

From an English statistical authority I take the following figures, showing the army budgets of various countries for the year 1913-14:

Japan	$48,500,000
Italy	82,000,000
Great Britain	137,000,000
United States	146,000,000
France	178,000,000
Germany	292,000,000
Russia	327,000,000

We thus see that there are only three nations that spent more money in the period named than we spent, and the figures given do not include our state troops, but only the Federal budget. Yet we are told by many people who should know that our army is a negligible factor and that even for such a job as pursuing a few bandits over the Mexican border its showing is "pitiful."

If that is so and if substantially the same is true of our navy, as we are told that it is, then is it not time for us to try to discover what the $146,000,000 does buy and whether or not some results worth while can be secured by an expenditure of money exceeding that of Great Britain and exceeded only by the three great military nations—France, Germany and Russia?

Modern warfare has been shown by the war now going on in Europe to be more than ever an engineering operation. It is organization pitted against organization, and machine pitted against machine.

Preparation for war is also largely an engineering work, and the nation which does most in making this work of preparation efficient—that is, in getting the largest possible results for each dollar expended—will have gone a long way in the work of "Preparedness" and will get the best support from its people, upon whom the burden of taxation falls.

Need of Legislative Action

By Ernest H. Peabody

The mistake this paper makes is in presupposing that the enormous work of organizing for industrial preparedness can be effectively projected and completed, with the dispatch which the circumstances make imperative, by the engineering fraternity of this country as represented by the engineering societies, working in the odd moments snatched from the task of making a living, without compensation and paying its own expenses.

It is indeed a satisfaction for us all to know that this important movement of Industrial Preparedness has been initiated and is being carried forward to far better purpose than the facilities available might promise. But the mere preliminary step of making an industrial inventory is a tremendous piece of work in itself. Can it be done by a society like ours or by representatives of similar societies? May we expect that even the enthusiastic army of engineer census-takers referred to by the author—in the little time available and with, comparatively speaking, a limited backing—may we expect that these men can satisfactorily accomplish this important work? Have we time to do it in this way? I think not.

It is our Government that must do this work and not the United States Naval Consulting Board, whatever may be the enthusiasm, self-sacrifice and ability of its members and whatever may be the help which this society's membership at large can give. I believe that the steps that this society should take are those which will put pressure upon our legislators to make an organized Government measure of this industrial census and all the thousand other important features which must be included in complete "preparedness against war" (to quote Mr. Garrison).

It is a mistake, in my opinion, to allow the impression to go abroad that the work which the Naval Consulting Board has begun and which is being promoted by the action of the allied engineering societies is sufficient and satisfactory and that it will fulfill the great needs of our country. We must go deeper to make this work effective; we must bend our energies along the line of stimulating public opinion, so that our representatives at Washington will be impressed and take the necessary steps to make the whole question of preparedness a Government policy.

The appointment of the United States Naval Consulting Board was an inspiration and of incalculable benefit to the country, but anything short of putting this matter of preparedness straight up to the legislative and executive heads of our Government as a national duty is merely playing with a problem that vitally affects our very existence as a nation.

Thorough Co-operation Needed

By J. P. Brophy

Industrial preparedness is an extremely vital question and the word "industrial" is so deep and reaches so far that it requires a vast amount of labor to impress those in a country of such magnitude as ours with its actual meaning.

To be industrial in the extreme means a genuine commingling of all lines of business and labor of all descriptions. It might easily be said that this country has at all times been awake to the meaning of the word industrial because we have up to the present time in all sections of the world been considered real leaders in a vast number of enterprises. To improve upon what has happened in the past means a genuine amalgamation of all with whom we deal. This means that the leading business men should have one thought—never to allow the business of this country to go backward.

I believe that the big thing in preparedness in any undertaking involves the best use of your thinking powers to plan in advance, being ever ready to meet the business enemy.

Competition after this war ceases will be somewhat severe from all sections of the world, although a vast number of bright business men are under the impression that we control the world from a manufacturing standpoint. Perhaps we do in a certain sense, but from an industrial standpoint business men should, if posible, have those in their employ thoroughly satisfied. Get men to work as a thoroughly organized body. This means homogeneous brain power, all thinking in one direction, as nearly as possible, and constantly having self-protection in mind.

This cannot be of great benefit to this nation, if it is not genuinely universal. An educational campaign seems absolutely necessary to teach all to work together, and this must be done with a great pride for our own country. It is a subject that requires a vast amount of thought, and it may be a difficult problem to get all bodies of men in business to think anywhere nearly alike. The trouble is, selfishness is too strong. We rarely ever give our neighbor any thought; and if we do not, there is little chance of real success. There is no question in my mind that the countries abroad will get busy immediately after this war ceases and unquestionably will be anxious to find markets in this country for their produce, at very inviting prices, for the reason that they will need the money and need it badly. It will be vastly different from the past. Their only alternative is to reach out for new markets with the idea of making headway regardless of large profits. Then it will be absolutely necessary for all lines of business in this country, which have to meet this kind of competition to be prepared to stand the test.

It is a difficult problem and will need a vast amount of time to get those interested in business, as well as the workingmen, thinking in the same direction. If they do not, the matter of industrial preparedness is liable to be forgotten, because it will not reach an actual working condition. To utilize the industrial resources of this country to the very best advantage, there must be a complete unification of all who participate either in a large or small degree. This can never be accomplished by a few individuals. The assistance of the Government must be had when taking into consideration new business in South America, the different colonies and the Orient.

Our banking facilities are extremely inadequate, and our merchant marine is not worth considering when we seriously contemplate doing business with South America. Notice the embargo on freight in the East in the last two months—no boats to carry our product abroad, and those that will be used for this purpose are not American ships.

An undertaking of this kind means not working at cross-purposes, but in conjunction with one another, having love of our country uppermost in our minds and taking into consideration that one man is intellectually stronger than another, not expecting too much from those who have not had equal opportunities. In other words, a little more solicitude for one another would be approaching the real foundation of industrial preparedness. We, as a nation, I am inclined to believe, are too far apart as individuals, for the reason that we are not all one people. That there are too many nationalities, many of whom have forgotten that this is their home for all time and that this great and free country should come first, while love of the place from which they came should have only second consideration, is partly responsible for this condition.

Industrial preparedness must be forced to a successful issue through the channels of governmental control. It means the proper distribution through the daily papers of advice, gathered after searching investigation, thereby getting into the minds of the masses the actual meaning of this word industrial.

Steel for Rifle Parts

By K. A. Juthe

The present activity in small arms and ammunition brings out several factors that seem serious enough to warrant a general discussion. I refer mainly to the military rifle. When orders began to come into this country over a year ago, the rifle-manufacturing interests were totally unprepared to take care of hurry-up orders, and the engineers in charge were up against a unique and at the same time serious situation. They were unable to secure the required number of skilled men for the preliminary work and also to secure the necessary material of the high standard wanted by the different governments. Considering that orders were placed with

different manufacturers for from 1,000 to 5,000 complete rifles per day, the magnitude of the undertaking can be partly comprehended; and a few figures show in which particular instance we were worse off than any superintendent or engineer in charge of such work had ever thought possible, for men have always before been procurable for almost all classes of work.

The gage problem was one of the most difficult, as we found that it takes at least 300 first-class gage makers six months to furnish the first working set, inspector's set and the master set necessary for guns in quantity. And when 1,000 complete rifles per day are figured on, it means that the working sets must be increased from one to ten and the inspector's sets from one to five, keeping the master set simply for reference. It has been conclusively shown that out of a total of practically 2,500 to 3,000 first-class gage makers in the country the supply was wholly inadequate to tackle several different propositions at the same time.

Jigs, fixtures and small tools require a small army of tool makers. It would take at least 1,000 tool makers one year to furnish tools of this kind for the output of 1,000 rifles per day. Therefore, in case anything happened that would make necessary an order from this Government for 5,000,000 rifles (which would be needed for a preparedness program, at least 1,000,000 rifles per year) we should be up against a proposition that would tax our tool plants to the utmost.

A suggestion for a central plant wherein tools and gages could be manufactured and sent out to different plants in case of trouble is one which the engineers should give careful consideration, as no manufacturing can be started until gages have first been made. It would seem as though a central plant for the manufacture of gages would be the proper thing. This should, however, be done in one plant laid out for that particular purpose under the supervision of one head, as it would be necessary that all gages bear the same relative characteristics with the same relation to each other as the finished part of the product. The gages can then be made in large quantities and sent to all the different manufacturing establishments doing this work.

As for tool making being done under central supervision, with regard to small tools, jigs and fixtures the proposition takes an entirely different aspect. Jigs and fixtures are largely made by individual concerns to suit their own particular machine tools for rapid interchangeable production. As no two manufacturing plants have the same tool-making facilities, it is practically impossible to standardize tools for such purposes; and jigs and fixtures would be of no value unless they were interchangeable under the majority of conditions existing. There seems to be a necessity for a standardization of parts, or at least some method devised whereby tools could be manufactured and jigs and fixtures made suitable to fit the conditions existing at each of the large manufacturing plants now engaged in similar work. These could be kept in stock; and as soon as occasion required, they could be handed over and manufacturing could proceed with practically no stop, excepting the necessary adjustments and preliminary inspections.

There is also the question of getting raw material into shape for actual manufacturing. The specifications for each government vary largely as to analysis and physical requirements. In some cases such requirements are more than a ballistic test has shown necessary as a factor of safety. There is no trouble to get, by heat-treatment, a certain analysis of steel to meet the required physical specification, but all steel furnished must possess machining qualities within certain limits. Sometimes a little careless handling gives us what we term a "dirty steel"; and although all requirements as to physical qualities can be met, the drilling and rifling of the barrel under such circumstances become a serious and heart-breaking problem.

The following have been thoroughly demonstrated as necessary steps in the making of a standard high-explosive rifle. (The small parts of the rifle can be taken care of, as far as hardening and heat-treatment are concerned, without much trouble): (1) The analysis of steel, (2) Manufacture of such steel with minimum waste, (3) Forging of breech end of rifles without harmful effects to the steel, (4) Heat-treatment of rifle barrels to give the highest physical properties wanted with a high degree of machining qualities.

These points also need careful attention and consideration: (1) Designing and standardization of parts, (2) designing and manufacturing of gages, (3) designing and manufacturing of interchangeable tools, jigs and fixtures, (4) supply of a proper quantity of kiln-dried lumber for the rifle stocks.

Men are being trained at the present time for almost every part of the manufacture of small and large arms and ammunition, so that as soon as the proper facilities are provided, no delay would be necessary.

Necessity for Proper Drawings and a Supply of Gages

By Frank O. Wells and Charles E. Smart

We do not need big armies or navies. What we do need in the way of preparedness to preserve peace is that our machine shops be equipped to manufacture munitions of war at a moment's notice. For over two years all the machine shops in the United States have been working for the Allies, for they had practically nothing else to do; yet even today new designs for jigs and fixtures for this work are upon the drafting boards, and new gages and tools are being made in hundreds of shops all over the country.

People have talked of having the Government make the ammunition, but those who are conversant with the subject know how absurd this proposition is. Well-trained men can be transferred in private factories at a moment's notice from the making of their regular products of peace to munitions of war, if they have tools and gages to work with.

We believe that the following points should be well considered: (1) The Government should call on all the drawings, books of instructions, gages, jigs and fixtures—in fact, all the special equipment necessary to produce munitions of war. (2) Drawings and books of instruction worked out to the minutest detail should be in the vaults in all the arsenals and navy yards, ready to be distributed to the various plants at short notice. (3) Gages, jigs and special fixtures should be also in vaults in the arsenals, to be given out at the same time as the drawings and books of instructions. (4) The operations and methods of handling the work necessary to make munitions of war should be carefully standardized in order that no matter in what section of the country such work is done, the cost will be the same, because the standardization of time means also standardization of price. (5) The present arsenals should be used more as experimental stations from which the private plants will get their instructions and information regarding the best methods of producing the goods they are called upon to manufacture. A number of private plants should be given small yearly orders of the parts that they are best adapted to produce, so as to keep the organization familiarized with the product.

It has been shown that the weakest spot in the present war is the lack of ammunition, particularly from 1- to 16-in. caliber, which is used by both army and navy. Herewith are given some statistics of the time that it would take to get prepared and to make ammunition alone:

A conservative estimate is that it would require 50 engineers, designers and draftsmen at least 50 weeks to prepare the drawings for the 17 sizes of shells now used by the United States Army, together with drawings for gages, jigs, fixtures and tools. To produce the gages, tools and fixtures for this work would probably require 800 men, well trained and in well-organized factories, at least 5 years, calculating that there are 300 working days per year. This would equip 100 factories, employing 2,000 men each, capable of producing a total quantity of 200,000 rounds per day. This number may look enormous, but we must not overlook the fact that twice this amount has been used in a single day in the present war by one of the combatants.

We have not mentioned the question of aëroplanes, rifles, battleships or a large number of other important parts of equipment which must also be provided for. This all talks of war; but what nation would dare to attack us, if they knew how well prepared we were? We, as a peace-loving nation, would surely never attack any other nation, and so perpetual peace would be assured.

Small Arms and Ammunition

By F. O. Hoagland

The shortage of both arms and ammunition in this country in case of immediate need is very apparent, but it is a fact that, owing to the great efforts in this line being made by private manufacturers, it would be possible to change this condition materially at very reasonable cost, if proper steps are taken without delay.

The Springfield and Rock Island arsenals are in good condition to turn out the .30 army Springfield rifle; and the Frankford arsenal can provide the ammunition for this rifle in limited quantities, although all of the arsenals are somewhat short-handed at present. Arrangements are also under way to manufacture the .45 caliber automatic pistol and its ammunition at the same arsenals.

The Government has at times placed contracts for some 10,000,000 rounds of this small-arm ammunition, divided among four or five private concerns in this country, but dur-

ing the last couple of years the orders were not accepted by the ammunition manufacturers on account of the 8-hr. working day being stipulated. This obstacle has now been removed, and the conditions are more favorable in this respect.

The quantities ordered have been too small to make it an object for the interested parties to go into the manufacture of this particular ammunition very extensively; and no private manufacturer has made any quantities of .30 Springfield army rifles, nor has he any special tools, fixtures or gages necessary for making them. The conditions are about the same in regard to the .45 caliber automatic pistol, as the company that brought it out a few years ago for the army service is the only private concern in this country equipped for its manufacture.

Judging from past experience and by the length of time it is taking manufacturing establishments at present, although having good organizations, to get ready to begin to fill orders for a product but slightly different from their regular lines, it is apparent that it will be necessary, if quick service should be required some day, to place several of these concerns in condition to meet the demand by placing orders for arms and ammunition without delay. Such orders should be of sufficient size to keep a small unit at work constantly, so as to keep the equipment in good repair and to have a number of trained workmen to form a nucleus for building up an organization in case of need. The Government arsenals could undoubtedly be of great assistance in preparing the special equipment of fixtures, tools and gages, but a few leaders and workmen in each plant, who are thoroughly familiar with the requirements, are absolutely necessary in order to get quick and sure response.

By loading a small portion of the cartridges only, just enough to check the production of shells and bullets, a fair supply of the latter could be accumulated and carried in stock at a cost of one-half of the loaded cartridges. Any danger of deterioration of the powders or primers would thereby be removed, the present European War having brought out very forcibly the seriousness of the condition when old ammunition failed to respond at the crucial moment.

Powder making has developed to such an extent that with a fair supply on hand at all times the loading could be carried out by the Government arsenals at a rapid rate and the troops supplied with fresh ammunition. Experience has proved that the supply of shells and bullets generally controls the output.

It is very important that, if anything is to be done in this line, it is done without delay, before the ammunition and arms manufacturers break up their engineering organizations, as they have nearly completed this class of work in connection with the contracts now on hand and are about to get down to actual manufacturing. Having had some very costly experience in getting together and training an efficient corps of engineers, they may not be very anxious to go through this same process again in the near future.

It is very important that if orders are placed with any private manufacturers they be employed constantly, as it takes from two to three months from the time the order is entered for the material to be prepared and the product to come through in fair quantities, even with a suitable equipment and a trained organization and under the best of circumstances.

All Gages Should Be Made in Government Shops

By John H. Barr

The industrial inventory for which provision has been made will greatly increase the military value of the industrial resources of the nation. The tentative scheme of this inventory is probably adequate as a basis of development of many of the civil industries into military supply plants. Its provisions will facilitate the production of such equipment as shoes, clothing, food, fuel, etc. Automobiles, aëroplanes and other transportation equipment suitable to military needs can be developed, and plants for making these can be brought to a state of preparedness for a much increased output under the stimulus of this plan. An extension of these methods or other means will develop a large potential supply of explosives.

In the matter of manufacture of arms and ammunition, however, it appears that special difficulties will arise, for uniformity and complete interchangeability are of the utmost importance in these most essential articles. It is well known that the methods and degrees of refinement in tool making vary widely among various factories regularly engaged on similar products. The uniform standard, which is vital in producing guns and ammunition for our military forces, requires a corresponding uniformity in the quality of the gages and tools for producing these supplies.

Clause (c) of the proposed agreement requires each shop to maintain corrected drawings and to construct one set of tools for such products as it might be expected to furnish. It would appear that the desired result may be more certainly attained by construction of such gages and tools in specially equipped Government tool factories controlled by a highly expert staff and manned by workmen of corresponding skill. These Government tool factories can construct all gages required and most of the important special tools. Drill jigs made in these factories can be used in any shop having suitable drill preses. Some variations exist among the machines of the numerous civil shops in the requirements as to drop-forging dies, punch-press dies and milling fixtures, but this will not seriously hamper the wholesale manufacture of such tools by the Government tool factories. The large production concentrated in the Government tool factories would be on a scale to permit real manufacturing methods in constructing standard tools. It is not necessary to expand this thought further, although it is capable of much extension.

There is in this proposed production of all the important tools in Government tool factories one other advantage that tends to a uniform and high standard of product. The prosecution of this high-class tool manufacture will involve some considerable production in the Government shops in thoroughly testing the equipment. This practice will develop a large corps of mechanics skilled not only in the making of these tools, but very familiar with their use and the requirements to be met by their output.

In case it becomes necessary to utilize the industrial equipment of the country to the utmost this corps of specialists would be a source from which to draw inspectors and instructors for duty in the private shops. Even one such man in a large private shop could render inestimable service in putting the plant upon an effective military basis. He would supply just that specialized technical knowledge that could not be expected of even the best of mechanics, who necessarily lack extended experience in production of military munitions.

Government Shops Should Be Sample Shops

By William B. Jackson

There is a tendency on the part of many who have not given the matter considerable consideration to feel that the Government of the United States might place itself in a position to own manufacturing establishments capable of fulfilling all the requirements of preparedness and to produce the necessary supplies and equipment to enable our country to withstand a serious attack from outside nations.

The sooner such an idea is rooted out of the minds of our people the better, since at best the Government can only own and operate what might be considered sample establishments for the production of the materials and supplies that would be necessary in case of a serious attack upon this country. Were the United States to be attacked by a formidable foe, it would require the most intense activity of any reasonable development that the Government might have in the line of the manufacture of munitions and supplies, together with the most intensive activity of every private manufacturing establishment that could be pressed into the service. One of the things that has been clearly demonstrated by the present war is the tremendous advantage gained by the country that is able to start into the fight with the ability to provide at once the necessary supplies to keep the organization going—and this entirely aside from the question of trained officers, engineer corps, soldiers and seamen.

One disquieting feature of our present situation is that the manufacturing establishments do not feel safe in making the broadly conceived and comprehensive plans for assisting the government in case of trouble, owing to the fact that there appears to be no reason for them to feel that the government itself may not enter their fields of activity and take away from them the business which might with propriety come to their hands during the periods of peace.

It would appear that this move on the part of the Government to make a thorough census of the industrial possibilities of our country as a part of the work of our Naval Consulting Board should lead to the development of a plan whereby our manufacturing establishments may be brought into hearty coöperation with the Government with profit to both the manufacturing establishments of the country and of the Government.

Editorials

Preparedness for Industry

Military power is only a form of industrial power. This is essentially the viewpoint of the mechanical engineers, as shown by their discussion at New Orleans of Spencer Miller's paper on "Organizing for Industrial Preparedness." The problems of developing the organizations and managing bodies that must control our industries in case of a national emergency were carefully considered from many aspects. The nature of all this discussion is shown by the excerpts printed on the immediately preceding pages. It is significant to find a large body of professional men, associated in a great national society, that is a unit in its belief on a matter of such vital importance.

Looking a little way into the future, there is another associated subject that the American Society of Mechanical Engineers might properly and profitably discuss at a forthcoming meeting. No man knows what part the United States may play in the future operations of the present European War. But these things we do know: The war will end some time; after its close the United States will face new and uncoped with conditions in the markets of Europe, probably changed conditions in the other foreign markets and possibly new industrial conditions at home. Should not the American Society of Mechanical Engineers at some future meeting discuss the great question of "Preparedness for Industry"?

Organizing for industrial preparedness for war is but one part of a much larger problem. Is it not wise to consider the greater need now that we have gained a little insight into it through discussing one of its most important parts?

Machinists and Shop Executives in South America

The number of machine tools in the machine shops of South America is given as 11,681. It is possible to give from Mr. Hood's records the number of machinists employed in those shops at the time of his recent visit. This total is 14,631, divided as follows into four groups according to the sizes of the shops: In shops employing up to 20 men each 3,243 machinists; from 21 to 50 men, 1,749; from 51 to 150 men, 2,129; and from 151 men each and upward, 7,510.

Dividing this total of 14,631 by the total number of machine tools recorded for the shops in which they work gives us a factor of 0.8 machine per workman. This is of course much higher than the average in the machine shops of the United States. In Vol. 41, page 653, we gave statistics for the machine shops of Cleveland, Ohio, showing that there was 0.36 machine tool for every machinist employed in that city. A comparison of these two ratios indicates the nature of the work done in the shops of South America. Repair work predominates.

As would be expected, the machinists in South American machine shops are very largely native South Americans. They are much like the type that is known in the north as "all round" machinist. Trained, as they are, on a great variety of work, they possess the ingenuity and adaptability of the old-fashioned millwrights. This very adaptability permits them to learn easily to use and operate any new machine tool that may come into their hands. At the same time their knowledge of manufacturing is very limited, and there is no shop which has anything approaching a system of manufacture such as that known as the American system for producing interchangeable parts.

The executives—managers and superintendents—of these shops have been drawn from all the industrial nations of the earth, although nearly one-half of them are native South Americans. Arranged on a number percentage basis according to nationality, they list as follows: Native South American, 47.5 per cent.; English, 18.5 per cent.; Italian, 16.2 per cent.; North American, 2.7 per cent.; German, 2.7 per cent.; French, 2.4 per cent.; Spanish, 2.3 per cent.; Dutch, 2.3 per cent.; Belgian, Portuguese, Austrian, Swiss and others, 5.4 per cent.

This classification according to race shows again the importance of putting all business correspondence and literature for South American countries into the languages that are spoken—Spanish and Portuguese. It also shows how little pioneer work North American executives have done in South American shops.

Modern Standards for Shop Electrical Apparatus

Machinery in any special field is more or less difficult to standardize, depending to some extent on the rapidity of change and the peculiar conditions surrounding its development. If development at any given time is complete and practically no further improvements are made, standardization may usually be brought about without great difficulty. Where, however, the advances in any field are rapid and as a consequence constant changes are taking place in design, standardization becomes difficult at any given time, owing partly to the fact that those responsible for the standards may not themselves be positive regarding fundamentals in the design of specific parts and partly because changes are continually taking place and any particular effort to standardize may be made obsolete before it has had time to prove itself under the test of extended use.

Standards, furthermore, may be of two general classes—namely, those confined to a given shop, on the one hand, and those, on the other hand, which include various plants of a common industry throughout the country, involving many concerns manufacturing approximately the same class of apparatus. In a single shop the problems of standards may well include such items as cutting tools and machine parts, jig and fixture parts, drawings and the like, and the problem resolves itself into fixing these standards for the best interests of the shop itself and in accord as far as possible with general practice.

When the attempt is made, however, to standardize the output of many plants, manufacturing as they do the same general product, the problems are vastly greater and include the necessity for coöperation among the various interests that will be affected.

Standardization in the electrical manufacturing industry involves practically the extremes of these various difficult phases of the problem. It covers a field where changes and developments are continually occurring at a rapid rate, and any attempt at satisfactory standards must of necessity include a great many plants throughout the country, because of the numerous larger and smaller manufacturing centers in the electrical industry. The comparatively recent issue of the Standardization Rules of the American Institute of Electrical Engineers in revised form is therefore an example of the possibilities of concerted coöperation. Coming out, as these rules did, first in 1899 and covering, in general, standards for generators, motors and transformers, we find them revised or changed in 1902 "as a result of changes and developments in the electric art," and subsequent revisions or changes occurred in 1905, 1906, 1907 (a complete rearrangement), 1911, 1914 and 1915.

The main conclusion from the foregoing is that much aggressive effort has been made to standardize the various branches of electrical equipment in spite of the phenomenal growth of the science; and it is of special interest to observe that the recently issued rules include a very complete classification of electrical machinery in general, a speed classification of motors, which is definitely related to shop practice, and a comprehensive treatment on the rating of electrical apparatus, with the proposed standards, as recommended, clearly stated.

To the practical mind, however, one of the items of greatest appeal in these rules is the suggestion that standard information be placed on the rating or nameplate of each piece of electrical apparatus. It certainly seems reasonable to conclude that a move in this direction will prove most beneficial to the user of such machines under shop conditions, thus rendering easier the intelligent transfer of information relating to any given machine from manufacturer to user. Nothing can well be more vexing than to become accustomed to one method of nameplate marking and then in a rush at some later time, when a good motor must quickly be substituted for a disabled unit, to find completely different data on the nameplate of the motor to be used, making it difficult to tell without some study and delay whether it will fill the needs of the case.

An example that may well be followed by other similar committees is the formal statement of the Standards Committee of the institute that suggestions looking toward improvement in these rules, when based upon experience gained in the application of the rules to general practice, are welcome. This kind of coöperation, while always desirable, is particularly so in cases of this kind, where the interests of those affected cover such a wide field and where the opinions of the many rather than of the few must be depended upon.

Life, Leisure and Play

Many of our younger readers and perhaps not a few of the older ones—men who are now hard at their life work—are looking anxiously forward to the time when their reward will be immunity from labor. How often do we hear such terms as, "When I retire," "years of leisure," "afternoon of life" and the like? Yet in those moderately rare cases when the leisure is eventually won and entered upon is it not more often a disappointment than a thing greatly to be desired?

In many cases this long-anticipated leisure often brings such a change of habits as to prove fatal either to health or to life. It seems to be necessary to health that the powers of a man be trained upon some definite task and held there year after year while vitality lasts. Not until the time comes in old age when sleep can no longer restore his vital forces should he stop work. Life seems to need a steady channel to run in, a steady stimulating aim, a definite trend toward something.

We feel a sort of pity for such men as many of our retired generals and admirals, who when they have relinquished their active service, find unused time and vitality upon their idle hands and minds. The current of their lives is thus thrown into eddies or settles into placid pools, and they begin to count themselves out of the world.

The great difficulty with most of us is that we do not play enough. The play of the business man should not be taken in a lump, but should be scattered along his career. It should be enjoyed not only in the spring or summer, but every week, every month. He who looks forward to it most needs it now. Play is a condiment: it is never the grand dish, and he who does not take it with his work never has it. Those men who continue to work when they could retire upon their means or their laurels work not only for happiness, but for life. They well know that play as the real business of life is the hardest work that man has yet devised.

Giving the Manager a Fair Show in a New Plant

Much has been written about the workman and how we can make his lot easier. This has had its effect, and in many shops there is wonderful coöperation, so that the workman has the best chance to make good. Systems have been evolved and the various departments modified to aid in this result. We wonder if similar thought has always been given to the men higher up—foremen, superintendents and managers.

We recently had called to our attention an instance where the ordinary courtesies extended to a workman were denied the manager. After accepting a new position, the manager was allowed to commence his duties without being introduced to the superintendent and foremen who were employed under him. This procedure caused trouble, worry and loss to all the parties concerned. The orders and advice issued were acted upon in a half-hearted manner, as the new manager's position had never been officially stated.

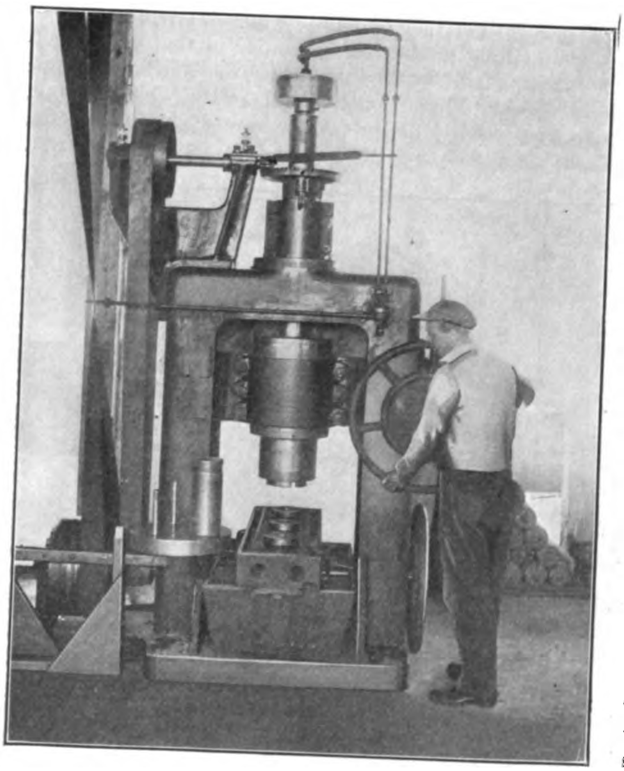
To overcome this disagreeable state of affairs, the manager had to go through the shop and introduce himself. As can be imagined, the result was a delay in production, and for a while there was a certain amount of ill feeling. All this could easily have been avoided if the owners had used ordinary thought and exercised a little horse sense when the new manager entered upon his duties.

Shop Equipment News

Vertical Shell-Boring Machine

In the design and construction of the vertical boring machine illustrated it was aimed to provide sufficient rigidity to insure, for instance, cutting powder pockets and diaphragm seats truly concentric with the outside wall irrespective of any eccentricity of the forged hole. The other special feature is the method of holding the shells inverted in the pneumatic chuck so that the chips drop out immediately upon becoming detached, thus avoiding any interference with the cutting tool.

The spindle is so cored that chuck jaws for any size of shell up to 6 in. in diameter may be inserted. This necessitates the enlargement of the lower end of the spindle and thereby serves to provide a large bearing surface. The bearing is tapered with the larger diameter at the bottom, the spindle surface being of semisteel and the bearing itself of hard babbitt. The feed motion is either by the handwheel, shown in front, or by power feed. The quick return of the spindle, either up or down, is accomplished by power or by hand.



VERTICAL PROJECTILE BORING MACHINE
Capacity, 6-in. diameters; power feeds, 0.007, 0.011, 0.016, 0.023, 0.034, 0.053 in. per spindle revolution; drive, 6-in. double belt; weight, 10,000 lb.

The heavy platen in which the tool holes will be noticed is carried in ways cast integral with the base. A platen centering device is provided so that each tool may be centered with the spindle. After the tool is centered, the platen itself is locked in place so that the centering pin takes none of the strain. The reduction in rotative speed between the lower countershaft and the spindle is in the ratio of 15 to 1.

The machine is a recent development of the Dunlap Machinery Sales Co., Dayton, Ohio.

Tool Post for Use with Multiple Tools

The necessity for rapid turning has developed many methods of using multiple cutting tools. The tool post shown herewith has been designed to secure this advantage in the plain engine lathe and without special tools, no change being necessary unless it is desired to use more tools than the tool block will hold. In this case a wider block is necessary.

The tool block in Fig. 1 is a drop forging, made narrow to allow close setting. It can be turned in any direction, and the blank T-nut can be readily fitted to any tool block.

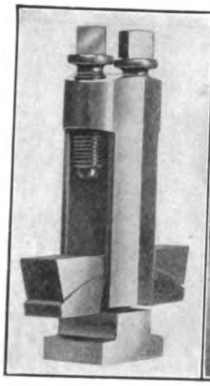


FIG. 1. THE TOOL POST

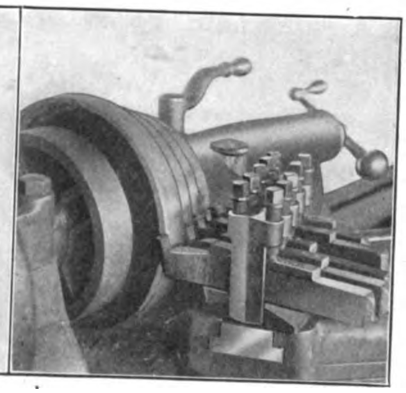

FIG. 2. FIVE TOOL RESTS AT WORK

Tool opening, [illegible]x1$\frac{7}{8}$ in.; width of body, 1$\frac{5}{16}$ in.; combined height of pillow blocks, [illegible] in.; tensile strength of sides, 50,000 lb.

Tilting is secured by two blocks, also drop forged, within the slot, avoiding the usual ring outside and saving the space ordinarily occupied.

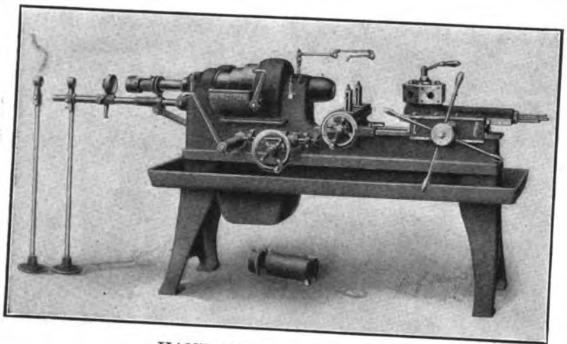
These tool posts can be readily grouped in any way desired; Fig. 2 shows one example—a four-step cone pulley. The two setscrews enable the tool to be held firmly, either level or in any tilted position within its range. A ring is also provided for use when the body of the tool post is turned so that the tool is directly over the slot in the block. Each tool is set to the required height and angle, and any single tool can be removed for grinding without disturbing the rest.

This tool post is known as the Rex and is made by the Rex Manufacturing Co., Hyde Park District, Boston, Mass.

Hand Screw Machine

To secure desired rigidity, the head and bed of this hand screw machine are cast in one piece, and the bed is ribbed to provide additional stiffness.

The spindle is a carbon-steel forging, bored and threaded to receive a collet nose. The turret is revolved



HAND SCREW MACHINE

No. 2 machine: Chuck capacity, 1 in.; diameter of turret holes, 1 in.; swing over bed, 14 in.; swing over cutoff slide, 6 in.; length to be turned, 6 in.; greatest distance from end of spindle to turret, 14 in.; horsepower required, 1½. No. 2 machine: Chuck capacity, 1½ in.; the other dimensions are proportionately greater

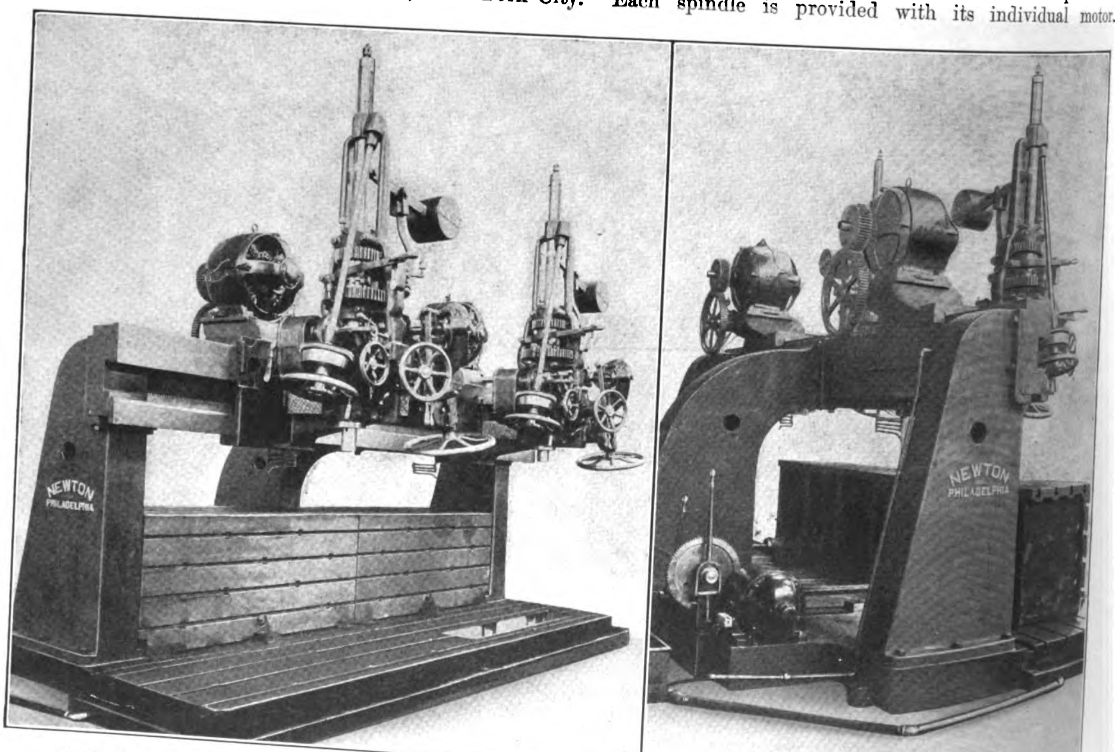
automatically by the backward movement of the turret slide. Handwheel feed for the cross-slide is provided, and positive stops for the longitudinal feed to the cutoff slide may also be furnished. The machine is made by the Himoff Machine Co., 128 Mott St., New York City.

Two-Spindle Drilling Machine

While this machine has been designed particularly for drilling locomotive frames, it can also handle general construction work on both large and small locomotives. The two spindles have an automatic geared feed, with vertical adjustment, through direct-connected gearing for the fast hand traverse and through a friction-clutched worm and wormwheel for slow adjustment. A departure in design makes the top spindle sleeve carry both the clutch and the spur-clutch gears.

Gears regulating the feed are mounted in a box, a small lever controlling the changes by means of a spring key. The spindle saddle has an in-and-out adjustment of 18 in., from 6 to 24 in. from face of rail. The cross-rail is of heavy box construction, with supporting ribs. There are two work tables, both adjustable on the floor plate, the two views showing them in different positions. These tables are also of box construction, with both vertical and horizontal working surfaces. The floor plate itself is provided with T-slots and forms a lower work table. The center upright is of special design to permit the tables, with their work, being adjusted to any desired position. They are handled by coarse-pitch screws, centrally located, which can be operated simultaneously or independently, either by hand or by power.

The drilling mechanism is similar to that of the radial machine built by the same firm—the Newton Machine Tool Works, Philadelphia, Penn.—with which a 3-in. hole was recently drilled at the rate of 3 in. per min. Each spindle is provided with its individual motor.



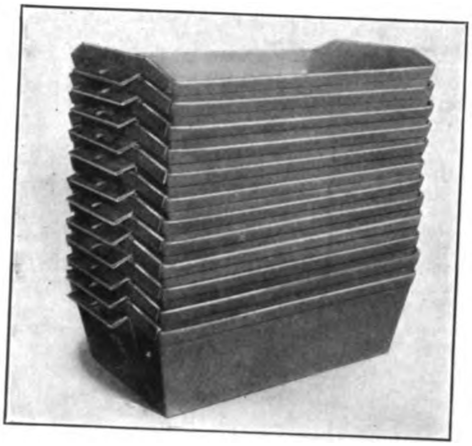
TWO VIEWS OF TWO-SPINDLE DRILLING MACHINE ESPECIALLY ADAPTED FOR LOCOMOTIVE FRAMES

Spindles, 4 in. in diameter; automatic feed, 18 in.; vertical adjustment, 18 in.; spindle speeds, 28 to 456 r.p.m.; feeds, 0.0078 to 0.0128 in. per revolution of spindle; No. 5 Morse taper; spindle centers, 48 in. to 180 in., or 15 ft.; maximum distance from floor plate to spindle 81 in.; work tables, each 20 in. wide by 26 in. high by 7 ft. 6 in.; work surface of floor plate, 39 in. wide by 210 in., or 17½ ft. long; floor space, 19x20 ft.; motors, individual electro-dynamic 10 hp. for each spindle, 300 to 1,200 r.p.m.; for moving tables, 5-hp. C. Q. General Electric

Nesting Tote Boxes

In the design of the tote box illustrated the chief consideration, in addition to strength and durability was to get a shape that would permit close nesting for convenience in transportation and storage.

The box is made from No. 18 gage material and is of one-piece construction, except for the handles. The latter are folded double and welded on. The box is so designed that near the corners, where the strain is greatest, the stock is of quadruple thickness, the side hem being continuous and running under the end hem. The raised end provides additional piling capacity in each box and permits a higher location of the handle, making more complete nesting possible.

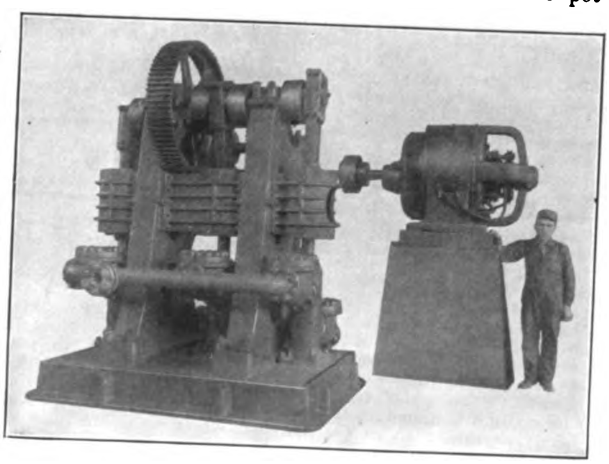


NESTING TOTE BOX
Dimensions at top, 16x10 in.; bottom, 14x8 in.; height per dozen nested, 18 in.; weight, 7 lb. each

The form of box shown is a recent product of the New Britain Machine Co., New Britain, Conn.

Triplex Hydraulic Pump

The illustration shows a new vertical triplex hydraulic pump designed and built by the Hydraulic Press Manufacturing Co., Mount Gilead, Ohio. It is of the pot-valve type and is capable of delivering a large volume of water against high pressure. The volume of water and the pressure depend upon the diameter of the plungers with which the pump may be equipped. These may vary from 4 to 5¾ in. The capacity of the pump varies proportionately with the intervening sizes of plungers.



TRIPLEX HYDRAULIC PUMP

Each plunger has a stroke of 12 in., with a normal speed of 45 strokes per minute.

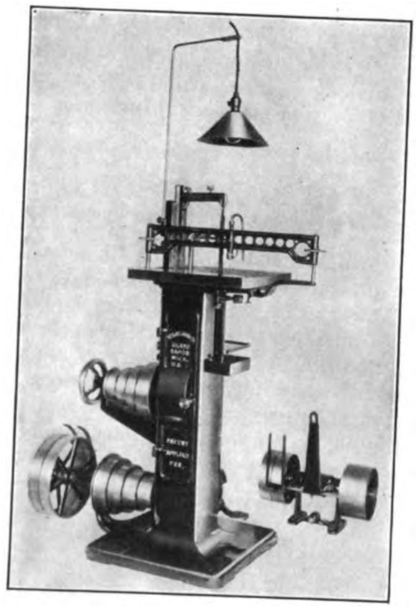
This pump is designed for direct-connected motor drive only and requires a 100-hp. motor for operating. The height of the pump is 10 ft., while the floor space required, without the motor, is 8 ft. by 5 ft. 9 in.

Die-Filing Machine

The illustration shows the most recent model of the die-filing machine made by W. D. Rearwin, Grand Rapids, Mich., and previously described on page 1006, Vol. 43.

An adjustable steel arm holds files from 4 to 12 in., straight or tapered. The machine is provided with a self-contained pump to remove filings from the work, so that the lines can be easily followed.

The graduated table tilts to 7 deg. in four ways independent of each other. A clamping arm holds the work. The arm is easily adjusted and is equally efficient on large or small pieces. A handwheel is provided to adjust the machine, and a foot shipper to start and stop it. The machine can be run with countershaft or a ½-hp. motor.



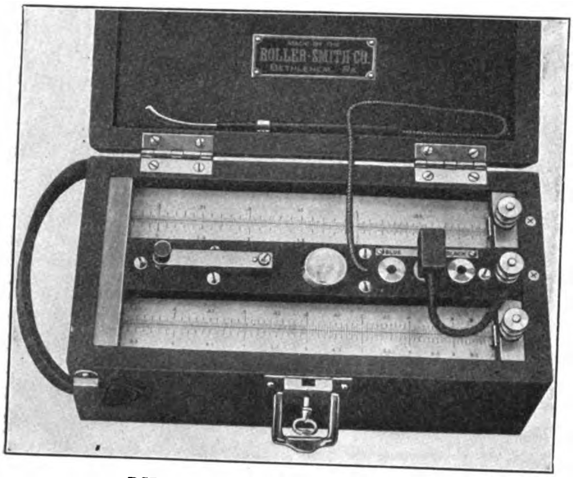
DIE-FILING MACHINE

Direct-Reading Ohmmeter

The direct-reading ohmmeter shown is the latest modified form of the type of portable ohmmeter made by the Roller-Smith Co., 203 Broadway, New York City, and was designed especially for measuring the resistance of relay points in electric signaling systems.

It is in general a slide wire bridge having self-contained galvanometer of sensitive but rugged design, self-contained dry cells which are conveniently located for renewal, galvanometer key, stylus and self-contained resistances.

The case is of hardwood, highly polished and provided with hinged top, latch and lock and leather handle.

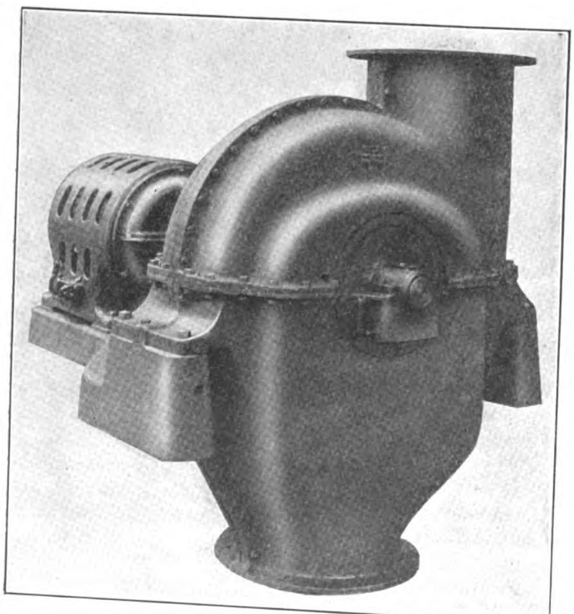


DIRECT-READING OHMMETER

There are three ranges—0-1, 0-10 and 0-100 ohms—each on a scale 15 in. long, each scale being of a different color—namely, blue, red and black. Means are thus provided for making all relay-point tests as well as many other resistance measurements within the range of the device.

Low-Pressure Turbo-Blower

The Ingersoll-Rand Co., New York City, has brought out a low-pressure turbo-blower to handle volumes from 3,000 to 35,000 cu.ft. per min. at from 1 to 2½ lb. This machine is adapted to such service as foundry cupola blowing, atomizing oil for oil burners, supplying blast to heating and annealing furnaces of various kinds, blowing air for water-gas generators, pneumatic conveying and ventilating systems of the various types.



LOW-PRESSURE TURBO-BLOWER

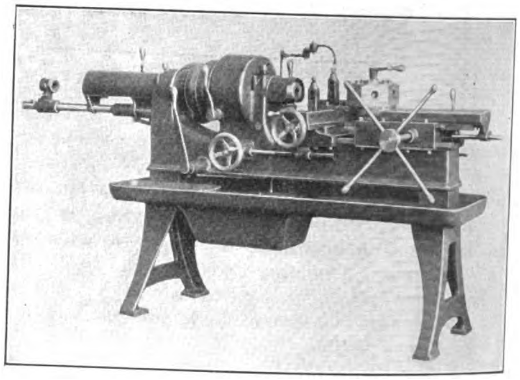
The turbo-blowers are of the single-stage double-flow type and are furnished for electric-motor, steam-turbine or waterwheel drive. Electric drive is generally employed for the classes of service mentioned, the high operative speed permitting direct coupling to the motor.

The turbo-blower maintains constant pressure while delivering any volume from zero to maximum demand and proportionately varying the electrical horsepower input.

Friction-Head Hand-Operated Screw Machine

The illustration shows a screw machine that has recently been placed on the market by the Kent-Owens Machine Co., Toledo, Ohio.

The bed and head are cast in one piece, and all gears are thoroughly protected. The spindle runs in bronze bushings provided with oil reservoirs. The turret is



FRICTION-HEAD HAND SCREW MACHINE
Capacity through wire feed, 1⅝ in.

provided with independent automatic stops for each turret station. The turret-tool locking bolts are offset to prevent injuring the shanks of the tools.

The cutoff slide is provided with a screw-operated hand adjustment in line with the spindle and is operated transversely by screw and handwheel. The machine is furnished either with or without power feed to the turret. Each machine is supplied with a pan and a lubricant pump.

NEW PUBLICATIONS

MILITARY PREPAREDNESS AND THE ENGINEER—By Ernest F. Robinson. Two hundred and twenty-four 4½x6½-in. pages; 75 illustrations; cloth bound. Clark Book Co., Inc., New York City. Price, $1.50.

This little book is the outgrowth of the material prepared by the author, who is a captain in the Corps of Engineers, N. G. N. Y., for a number of lectures given before engineering societies. The purpose behind its preparation is to place before the engineers of the United States accurate information as to the opportunities and limitations that will confront the civilian engineer in the event of war. It also shows what each one might do to prepare himself to meet the personal responsibility that would devolve upon him in case of war.

The entire book deals with the engineer activities of the army and does not touch at all upon the production of munitions. It is therefore of interest to the engineers who would enlist for active service. The subjects treated are indicated by the chapter headings, which are as follows: Introductory. How To Obtain a Military Training, The National Guard, Military Organization, Military Administration, Engineer

Troops in the Field, Fire Action, Field Fortifications, Obstacles, Siege Work, Demolitions, Military Bridges, Topographical Sketching, Needs of the Engineer in War, Conclusion.

It is undoubtedly wise for every engineer who has failed to avail himself of the opportunity to hear the military lectures that have been given during the past winter to read this book. It is estimated that for an army of 1,000,000 men 60,000 engineers would be required. Of these, 2,000 would be officers and 11,500 noncommissioned officers. These figures indicate the extent of the need of engineering experience in case of war. At the same time civilian engineering exeprience needs to edge before the engineer from private life can pass into the be supplemented by an enormous amount of military knowl- ranks of the army and become an efficient unit thereof.

THE TESTING OF MACHINE TOOLS—By George W. Burley. Two hundred and twenty-six pages, 4¼x7½ in.; 110 illustrations; indexed; cloth bound. Published by D. Van Nostrand Co., New York City. Price, $1.25.

Far too little attention is paid to the testing of machine tools. Thus this book enters a field where it should be welcome. In a series of eight chapters the author presents well-known established methods for the testing of individual parts of machine tools, shows numerous testing devices (including indicators of many kinds), shows how feeds and speeds should be observed, how cutting force should be measured, how power should be ascertained, and in Chapter IV presents much illuminating information on machine-tool efficiency.

He gives the overall efficiency of the lathe as 62 per cent., and of its slide rest as 13 per cent. The average efficiency value for a high-speed drilling machine is 77 per cent.; of a milling machine, 86.6 per cent., and of a shaper, 41.8 per cent. No factors are given for the planer, but it is stated that the results are similar to those presented for shapers.

The scope of the work is indicated by the chapter headings, which follow, and these also give a hint of the value of the work to the machine-tool builder and user. The chapter headings are: Introduction, Tests on Machine-Tool Elements for Accuracy, Machine-Tool Speed and Feed Tests, Machine-Tool Mechanical Efficiency Test, Cutting-Force Tests, Output and Power-Consumption Tests, Comparative Tool Testing, Commercial Machine-Tool Testing.

THE THEORY OF MACHINES—By Robert F. McKay. Four hundred and forty 5½x9-in. pages; 407 illustrations; indexed; cloth bound. Longmans, Green & Co., New York City. Price, $4.20 net.

Reviewed by DEXTER S. KIMBALL*

The author of this treatise states that it is an attempt to deal in a comprehensive manner with the large amount of subject matter which is included under the heading of the theory of machines. It is intended for the use of engineering students and practicing engineers. The book is in three parts as follows: Part I, Mechanics; Part II, Kinematics of Machines; Part III, Dynamics of Machines.

Part I consists of five chapters covering about one-sixth of the total subject matter. In it are discussed such topics as plane motion of a particle, force and torque, work and energy and kindred subjects that are commonly included in American books on analytic mechanics, so called.

Part II occupies one-half the volume and deals with motion in machines from the standpoint of pure mechanism. The discussion in this section corresponds closely to similar discussions in American textbooks on mechanism, though in some cases, as for instance in his treatment of belts and rope drives, the author considers the practical design of such machine elements.

Part III occupies about one-third of the book. In this section are discussed friction, static equilibrium of machines, turning-moment diagrams, governors, balancing, brakes and dynamometers. The subject matter of this section, therefore, is partly such as is covered by American books on mechanics and partly such as is discussed in American works on machine design.

It will be evident that it is difficult to make a comparison between this treatise and American books on kindred subjects where the arrangement is quite different. The discussion in Part II on kinematics compares favorably with books on mechanism now in use in American colleges as a preparation for engineering work. The subject matter of Parts I and III is usually included in mechanics in American texts, but the content would not be considered sufficient for the preparation of engineering students.

Portions of the subject matter in Part III are frequently included in books on machine design, and the author's treatment of some of these topics is not, in general, very satisfactory. One is surprised, for instance, to find no mention of the Morse chain, though the Renold chain is described. The discussion of the strength of flywheels is very weak, as is also the treatment of the lubrication of bearings in its influence on friction. The experiments of Tower are referred to, but Lasche's monumental work is not mentioned.

The treatment of the several topics is sound, no doubt, and the book may be of use as a reference for teachers and may perhaps be sufficient for the needs of certain polytechnic schools. With the possible exception of Part II, however, it it too limited in its scope to be of use in the higher technical colleges, where mechanics, kinematics and machine design are specialized and comprehensive courses. Engineering and the sciences on which it rests have become so widely extended that any book which aims to treat of several of these branches must necessarily be so concise, on the one hand, as to resemble a handbook or run a risk of being unbalanced in content or superficial, on the other. An excellent feature of the book is the list of graded problems at the end of each chapter.

*Professor of Machine Design and Construction, Sibley College, Cornell University.

PERSONALS

H. E. Streeter, who for several years was the Canadian representative of the Heald Machine Co., Worcester, Mass., is now works managers of the Precision Tool and Machine Co., Ltd., Montreal, Canada.

H. C. White, formerly production engineer of the Curtiss Motor Co., and previously department superintendent with the Pierce-Arrow Motor Car Co., has become factory manager of the Holt Mfg. Co., Stockton, Calif.

John A. Camm has resigned his position as sales manager of the Kearney & Trecker Co., Milwaukee, Wis., to become vice-president and general sales manager of the recently organized Cleveland Milling Machine Co., Cleveland, Ohio.

BUSINESS ITEMS

The McMaster-Carr Supply Co., Chicago, Ill., announces the election of Harry Channon as president and James A. Delaney as vice-president.

The Hydraulic Press Mfg. Co., Mount Gilead, Ohio, has opened a branch office at 416 Citizens Bldg., Cleveland, Ohio, in charge of Chas. E. Newell.

The headquarters of the S. K. F. Ball Bearing Co., which have been for several years located at 50 Church St., New York City, have been removed to the new home office in Hartford, Conn.

FORTHCOMING MEETINGS

National Metal Trades Association. Annual meeting, Apr. 27-28, New York, N. Y., Hotel Astor. H. D. Sayre, secretary, Peoples Gas Building, Chicago, Ill.

American Society for Testing Materials. Annual meeting June 27 to July 1, 1916, Hotel Traymore, Atlantic City, N. J. Edgar Warburg, secretary, University of Pennsylvania, Philadelphia, Penn.

American Society of Mechanical Engineers. Monthly meeting first Tuesday. Calvin W. Rice, secretary, 29 West Thirty-ninth St., New York City.

Boston Branch National Metal Trades Association. Monthly meeting on first Wednesday of each month, Young's Hotel. W. W. Poole, secretary, 40 Central St., Boston, Mass.

Providence Association of Mechanical Engineers. Monthly meeting fourth Wednesday each month. J. A. Brooks, secretary, Brown University, Providence, R. I.

New England Foundrymen's Association. Regular meeting second Wednesday of each month. Exchange Club, Boston, Mass. Fred F. Stockwell, 205 Broadway, Cambridgeport, Mass.

Engineers' Society of Western Pennsylvania. Monthly meeting third Tuesday; section meeting, first Tuesday. Elmer K. Hiles, secretary, Oliver Building, Pittsburgh, Penn.

Rochester Society of Technical Draftsmen. Monthly meeting, last Thursday. O. L. Angevine, Jr., secretary, 857 Genesee St., Rochester, N. Y.

Superintendents' and Foremen's Club of Cleveland. Monthly meeting third Saturday. Philip Frankel, secretary, 310 New England Building, Cleveland, Ohio.

Western Society of Engineers, Chicago, Ill. Regular meeting first Wednesday evening of each month, excepting July and August. J. H. Warder, secretary, 1785 Monadnock Block, Chicago, Ill.

Philadelphia Foundrymen's Association. Meetings first Wednesday of each month. Manufacturers' Club, Philadelphia, Penn. Howard Evans, secretary, Pier 45 North, Philadelphia, Penn.

Technical League of America. Regular meeting second Friday of each month. Oscar S. Teale, secretary, 35 Broadway, New York, N. Y.

Prices--Materials and Supplies

IRON AND STEEL

Pig Iron—Quotations were current as follows at the points indicated:

	Apr. 21, 1916	One Month Ago	One Year Ago
No. 2 Southern Foundry, Birmingham	$15.00	$15.00	$10.75
No. 2 X Northern Foundry, New York	20.75	20.50	14.75
No. 2 Northern Foundry, Chicago	19.00	19.00	14.25
Bessemer, Pittsburgh	21.95	21.95	14.90
Basic, Pittsburgh	18.95	19.20	13.90

5	43.12	31.08	68.30	46.62
6	55.68	40.32	91.20	60.48

Bar Iron—Prices are as follows in cents per pound at the places named:

	Apr. 21, 1916	One Month Ago
Pittsburgh, mill	2.50	2.45
Warehouse, New York	3.15	3.10
Warehouse, Cleveland	3.25	3.25
Warehouse, Chicago	3.10	3.10

Cold Drawn Steel Shafting—From warehouse to consumers requiring fair-size lots, the following quotations hold:

		One Month Ago
New York	List price plus 20%	5% from list
Cleveland	List price plus 20%	List price
Chicago	List price plus 10%	List price

Boiler Tubes—From Pittsburgh, the following are the less-carload basing discounts for lap-welded boiler tubes:

1¼ and 2 in.	47%	3½ to 4½ in.	56%
2¼ in.	44%	5 and 6 in.	49%
2½ and 2¾	50%	7 to 13 in.	55%
3 and 3¼	55%		

These discounts apply to standard gages and to even gages not more than 4 gages heavier than standard. For long tubes charge 10% net extra as follows: 1¾ in. size over 18 ft. and not exceeding 22 ft.; 2 to 3 in. sizes over 22 ft. and not exceeding 24 ft.; 3¼ to 13 in. sizes over 22 ft. and not exceeding 25 ft.

High Speed Tool Steel containing from 10 to 18% tungsten sells as follows per pound in New York:

Billets ....$2.35 Bars $3.00

Swedish (Norway) Iron—This material per 100 lb. sells as follows f.o.b. places named:

New York Today	New York One Year Ago	Cleveland	Chicago
$5.50	$3.25	$5.05	$4.25

In coils an advance of 50c. is usually charged.

METALS

Miscellaneous Metals—The present quotations in cents per pound, with a comparison of practically a month and year ago, are as follows:

	New York Apr. 21, 1916	New York One Month Ago	New York One Year Ago
Copper, electrolytic (carload lots)	30.00	27.00	18.00
Tin	50.00	49.50	43.00
Lead	7.75	8.50	4.20
Spelter	19.87½	18.00	12.00
ST. LOUIS			
Lead	7.75	8.40	...
Spelter	19.25	17.87½	...

At the places named, the following prices in cents per pound prevail:

	New York Apr. 21, 1916	New York One Month Ago	New York One Year Ago	Cleveland	Chicago
Copper sheeets, base	37.50	35.50	22.50	36.50	35.50
Copper wire (carload lots)	36.50	35.50	19.00	34.50	37.00
Brass rods, base	41.50	37.50	18.25	36.00	38.00
Brass pipe, base	44.50	41.50	21.00	43.00	46.00
Brass sheets	40.50	37.50	18.50	36.00	38.00
Solder ½ and ½ (case lots)	37.87½	30.50	32.00	35.50	34.75

Old Metals—The following are the dealers' purchasing prices in cents per pound:

	New York Apr. 21, 1916	New York One Month Ago	Cleveland Apr. 21, 1916	Cleveland One Month Ago
Copper, heavy and crucible	24.50	23.00	25.00	25.00

The Boston Duck Co. has awarded the contract for the construction of a 5-story, 130x400-ft. mill at Bondsville, Mass. Estimated cost, $275,000.

The contract has been awarded for the construction of an addition to the plant of the Massachusetts Rubber Co. at Cambridge, Mass. Estimated cost, $35,000.

The contract has been awarded for the construction of a 4-story addition to the plant of the Bay State Paper Co. at Dalton, Mass.

The Central Worsted Co. plans to construct a 2-story addition to its plant at Hartford, Conn. Estimated cost, $40,000.

MIDDLE ATLANTIC STATES

The Superior Manufacturing Co., Hoosick Falls, N. Y., manufacturer of knit goods, has awarded the contract for a 4-story addition to its plant. Estimated cost, $30,000.

The National Air Cell Co., New York, N. Y. (Borough of Brooklyn), manufacturer of asbestos for pipe covering, has acquired a site in the South Cove section of Jersey City, N. J., and will construct a reinforced-concrete factory. John A. Schawarth is Mgr.

Plans have been prepared for an addition to the plant of Thomas Oakes & Co., Bloomfield, N. J., manufacturer of woolens. Estimated cost, $15,000. Noted Apr. 20.

An addition will be built to the plant of the International Oxygen Co., Newark, N. J.

Plans have been prepared for 2 additions to the plant of Marden, Orth & Hastings, Boston, Mass., on Newark Meadows, Newark, N. J., manufacturer of oils and acids. Estimated cost, $75,000. Noted Jan. 27.

The contract has been awarded for 2 additions to the plant of the Merck Chemical Co., Rahway, N. J.

Press reports state that the Elizabeth Sash, Door and Supply Co., Roselle Park, N. J., will construct four 2-story buildings at its plant.

Bids are being received for the construction of additions to plant of Alexander Bros., 414 North 3rd St., Philadelphia, Penn., for the manufacture of leather belting.

A cold-storage plant will be constructed on Enterprise St., Pittsburgh, Penn., by the Independent Packing Co. Estimated cost, $60,000.

SOUTHERN STATES

The Richmond Cold Storage Co., Richmond, Va., will construct a 5-story reinforced-concrete plant.

C. C. Coddington and associates, Charlotte, N. C., plan to construct a factory for the manufacture of tires.

The Magnet Knitting Mills, Clinton, Tenn., plans to construct a 2-story factory. Estimated cost, $10,000. J. D. Allsup & Co., Chattanooga, Arch.

The Waller Manufacturing Co., manufacturer of furniture, has purchased a plant at Lexington, Ky., and plans to construct additions.

MIDDLE WEST

The Wovenright Knitting Co., 5815 Kinsman Rd., Cleveland, Ohio, will build a 2-story, 55x63-ft. addition to its factory at Cleveland. Estimated cost, $10,000.

The Monarch Tag Co. is constructing a 2-story, 60x135-ft. factory on East 5th St., Dayton, Ohio. Estimated cost, $35,000. Noted Mar. 23.

The Emmerson Sash and Door Co., recently incorporated, plans to construct an addition to its plant at Marion, Ohio.

The Cincinnati Can Co. contemplates the construction of a 1-story factory at St. Bernard, Ohio. Estimated cost, $20,000. G. F. Edwards, Eggleston Ave. and 4th St., St. Bernard, is Supt.

The contract has been awarded for the construction of a 2-story, 76x130-ft. factory at Toledo, Ohio, for the Hettrick Bros. Co., manufacturer of awnings, tents and canvas beltings. Estimated cost, $20,000.

The G. I. Sellers & Son Co., manufacturer of kitchen cabinets, plans to construct additions to its plant on North 13th St., Elwood, Ind.

The contract has been awarded for the construction of a 3-story, 38x60-ft. addition to the plant of the Wabash Cabinet Co. at Wabash, Ind. Noted Mar. 16.

Plans are being prepared for the construction of a 3-story, 50x100-ft. factory at Detroit, Mich., for the Detroit Cabinet Co. Estimated cost, $90,000. Frank Clipper, 988 Riopelle St., Secy.

The Globe Knitting Works contemplates constructing an addition to its factory on Commerce Ave., S. W., Grand Rapids, Mich.

The contract has been awarded for the construction of an addition to the plant of the Hawthorne Paper Co. at Kalamazoo, Mich. Estimated cost, $35,000. Noted Jan. 13.

The American Shoe Stock Co. has awarded the contract for the construction of a 2-story, 52x100-ft. factory at Centralia, Ill.

The Patent Novelty Co. has awarded the contract for the construction of a factory at Fulton, Ill.

The Chicago Rubber Clothing Co. has awarded the contract for the construction of a 1-story, 60x125-ft. factory at Racine, Wis.

Bids will soon be received for the construction of a 4-story, 80x144-ft. factory at Sheboygan, Wis., for the John C. Nicholas Harness Co., Janesvile. Estimated cost, $25,000. Noted Feb. 3 and 17.

WEST OF THE MISSISSIPPI

Plans are being prepared by J. Webster, Arch., for a packing plant for George Rath & Son, Dubuque, Iowa.

The contract has been awarded for the construction of a 2-story factory for the Hugo Manufacturing Co., 310 West 2nd St., Duluth, Minn., manufacturer of specialties. Estimated cost, $25,000. Noted Apr. 20.

The Daniel Shoe Co., 415 South St., Wichita, Kan., has awarded the contract for a 2-story addition to its plant. Estimated cost, $15,000. Noted Apr. 6.

The Du Pont Powder Co. will build a powder mill at Dawson, Mont. W. J. Laird, Dawson, Arch.

F. C. Bretsnyder, of Bell Oil Co., St. Louis, Mo., and others are interested in the construction of an oil refinery at St. Louis. The company is in the market for machinery.

The plant of the Interstate Compress Co., Hobart, Ark., recently destroyed by fire will be rebuilt.

WESTERN STATES

H. W. Etz, J. A. Gumm and C. E. Goetz plans to construct a canning plant at Benson, Ariz. Estimated cost, $10,000.

Plans have been prepared for the construction of a 2-story, 50x72-ft. cold-storage plant at North Yakima, Wash., for the Yakima County Horticultural Union. Estimated cost, $25,000.

The Standard Furniture Co. has purchased a site at 4th Ave., S. and Walker St., Seattle, Wash., and will build a factory.

The Inland Empire Paper Co. has awarded the contract for the construction of a sulphite mill at Spokane, Wash.

Plans have been prepared for the construction of a 2-story addition to the plant of the Hood River Canning Co., Hood River, Ore.

CANADA

The Acme Rubber Co. will build a factory at Brampton, Ont. Estimated cost, $30,000. F. D. Law, 471 Yonge St., Brampton, is interested.

The Waddell Preserving Co. will build a factory at Brantford, Ont., and install machinery. J. A. Waddell is Secy.

The Mitchell Woollen Mills Co. will construct an addition to its plant at Mitchell, Ont., and install new machinery.

Two kinds of advertising the American Machinist does not want:

Advertising of machine tools made for "export only"—

Advertising of any equipment that will not stand the light of Truth—about which the truth cannot be and is not told.

Only reliable products can be continuously advertised.

Manufacturing British 8-In. Shells in 4½ Hours--I*

By Fred H. Colvin

SYNOPSIS—The necessity for lifting shells by mechanical means introduces a new factor and one that adds much to the handling time. The illustrations show several forms of hooks and clamps, special lathes, heavy boring tools, single- and double-tooling for lathe carriages and formers or cams for both turning and boring. While there are no startling innovations, the methods have all been carefully worked out and are giving good results, as will be seen by the operation times.

The manufacture of the 8-in. shells involves several problems not presented by shells of smaller caliber, the first noticeable difference being in the handling. Owing to the greatly increased weight over the smaller sizes, tackle is required for putting the shells into and taking them out of the machine. This lifting is done in various ways, as will be seen in the different illustrations as well as in the different forms of handling devices grouped together in Fig. 3.

The necessity for these aids will be made clear when we realize that the blanks or rough forgings weigh 250 lb. each, while the finished shell weighs 177 lb. This figure, however, includes the adapter plug, which is screwed into the base, as shown in Fig. 1. The plant illustrated has been built especially for making these shells and consists of a one-story building 88x128 ft., divided into four 22-ft. saw-tooth bays running lengthwise of the building. The shop is divided into eight 16-ft. sections by columns and roof-beams running in the other direction, giving post centers 22x16 ft.

Raw material comes in from the cars at one corner and traverses in regular order up and down the different bays, as shown in Fig. 2, receiving its final baking, after being varnished, at the same end, but on the opposite side, from which it started. From here it goes to the bonded warehouse in charge of the British inspectors.

The shell itself is illustrated in detail in Fig. 1, with all principal dimensions. It ordinarily consists of but two parts—the body and the adapter plug, which screws into the base. There is also a provision by which any shell that is too large in the nose to pass inspection may be rebored and a special adapter screwed into it. The dimensions of this adapter are also given.

Coming in from the forge shop, the shells are handled by the type of hook seen at A, Fig. 3, this being so balanced that it hangs with the open end lower than the nose, so as to avoid all danger of accidentally slipping off and injuring a workman.

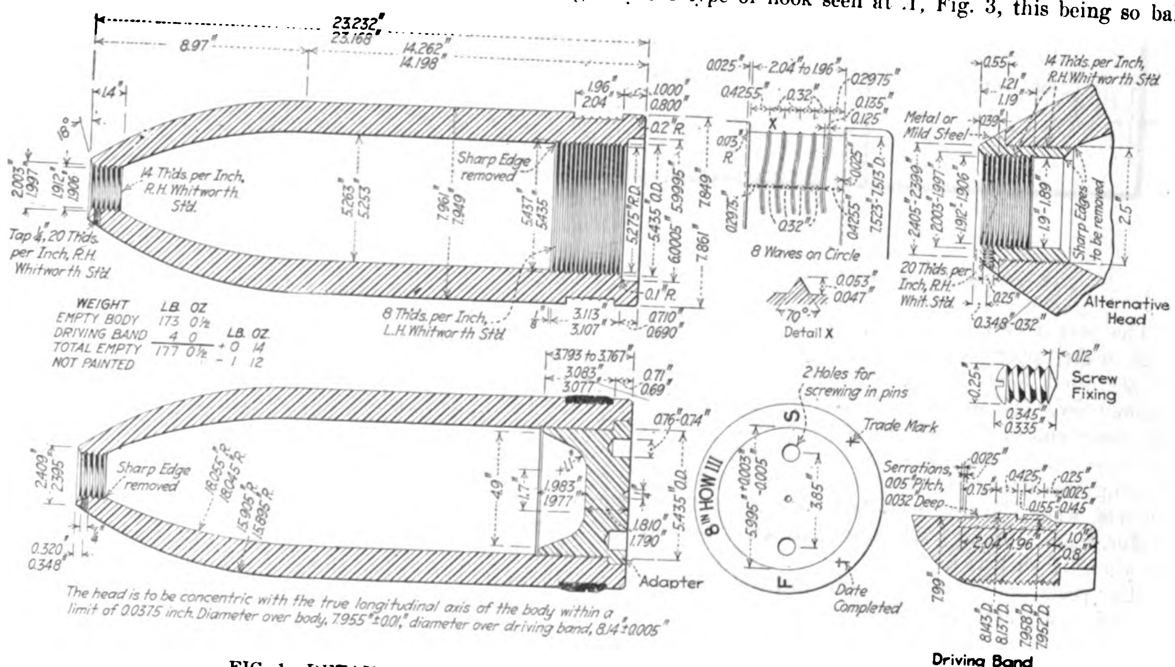

FIG. 1. DETAILS OF THE 8-IN. HIGH-EXPLOSIVE HOWITZER SHELL

The First Operation—Drilling the Nose

The first operation is the drilling of a hole in the nose, which is done on a W. F. & John Barnes drilling machine that happens to be available. A special drilling fixture of the turntable variety carries two mandrels, as in Fig. 4. These mandrels have a ring A at the upper end, which fits inside the bore of the shell near the nose, so as to center the shell from the inside, but at the same time leaves plenty of room for the nose drill to break through without interfering with the mandrel. Details of these mandrels appear in Fig. 5, only one spindle being given.

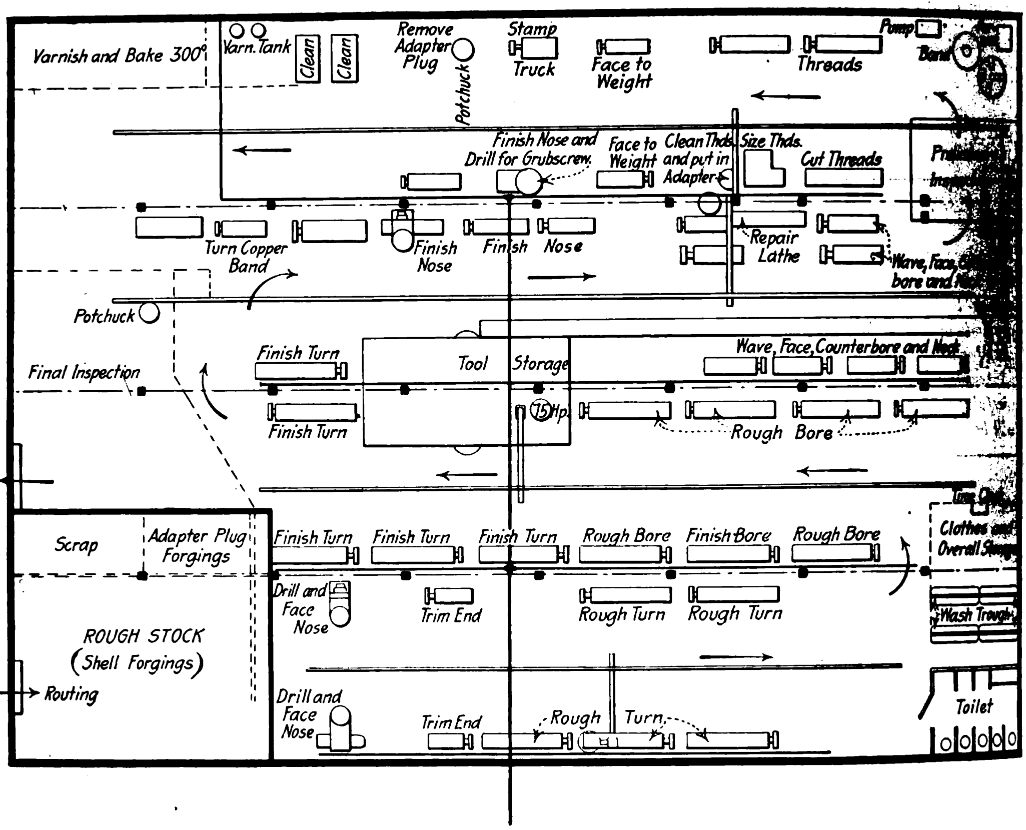

FIG. 2. FLOOR PLAN AND LAYOUT OF MACHINERY FOR MAKING 1,000 8-IN. SHELLS PER WEEK

The post A carries the centering plunger B, which is kept in the upper position by the spring C. The weight of the shell forces the plunger B down, so that the tapered lower end forces out the three fingers D to center the lower end of the shell while the collar on B centers the upper end. The shell is centered by the hole in the forging, it being easier to take care of eccentricity on the outside, where turning tools and carriages can be made stiffer, than in boring. The spring E throws the finger D in when the shell is removed.

The posts are mounted on the turntable F, which is carried on a central ball bearing H and has two indexing positions. The base G carries the indexing pin J operated by the lever I and is also provided with a raised edge to retain the lubrication. Stepping on the lever I withdraws the indexing pin J and also throws the ball bearing into action, making it easy to turn the table F. Releasing the lever allows the table to rest on the large and substantial annular bearing of the base.

This drilling fixture has a swinging plate C, which centers itself over the shell to be drilled and also carries the drill bushing. It can be swung in either direction, so that only one drill bushing is required for both mandrels, as can be seen in Fig. 4. The facing cutter is shown at D.

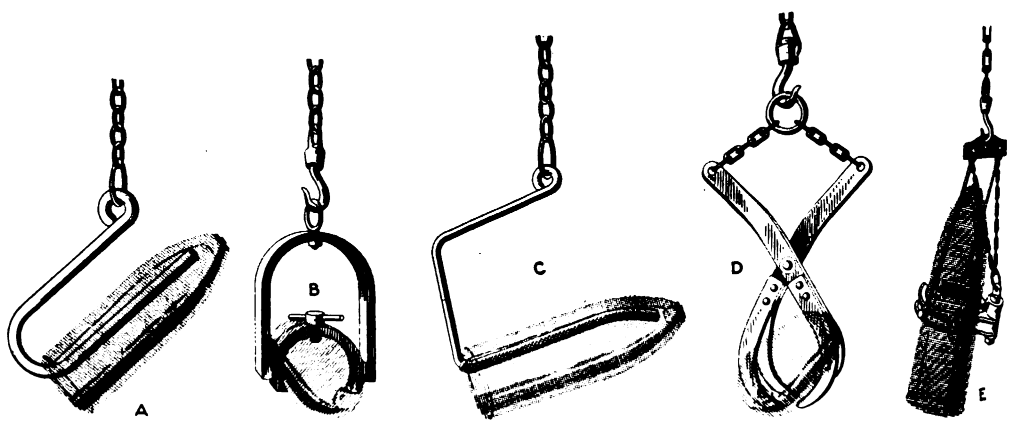

FIG. 3. TYPES OF HOOKS AND CLAMPS USED IN HANDLING 8-IN. SHELLS FOR THE VARIOUS OPERATIONS

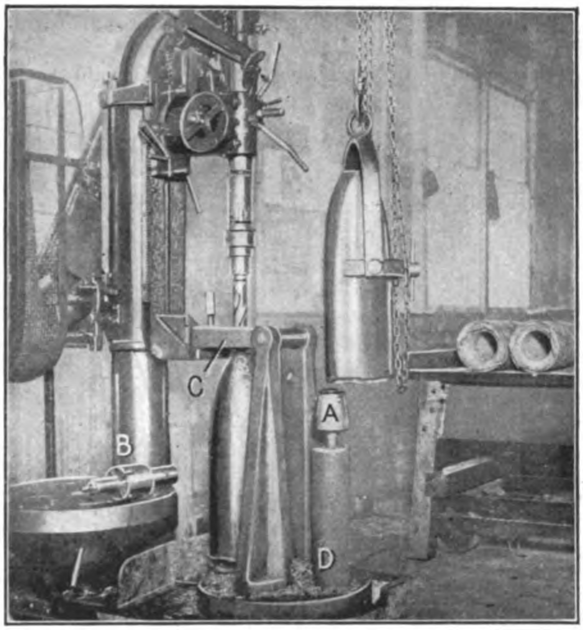

FIG. 4. OPERATION 1: DRILLING NOSE, $1\frac{11}{16}$-IN. DRILL
Machine Used—W. F. & John Barnes vertical drilling machine.
Fixtures—Revolving stand with drill bushings.
Gages—None.
Production—8 min. each.

After the hole is drilled, the shell goes to a special Root & Van Dervoort cutting-off machine, Fig. 6, with a spindle large enough for the shell to be slipped inside and held by three substantial screws. This places the shell inside the main bearing and avoids all overhang, permitting a cutting speed of from 35 to 40 ft. per min. with a heavy feed. In order to assist in centering the shell so that the ends shall be square with the bore, there is a tapered stop or plug on the inside of the spindle, which enters the hole already drilled in the nose and centers that end of the shell, while the outer end is clamped by the three screws in the chuck previously referred to. This stop also locates the shell for cutting off to length.

After this cutting-off operation the heat number, which had previously been stamped on the body of the shell, is transferred to the end, to prevent its being lost in the turning operation.

Rough-turning comes next, Fig. 7, the shell being tested at the point to see if it will true up to the required size. In case the point is somewhat eccentric, it can be coaxed over a limited amount by means of special brass cups A, of varying thickness, which are placed over the ends of one or more of the locating and holding points in the work-holding mandrel. These mandrels, illustrated in Fig. 8, are operated by air chucks. The shell is set by the bent gage, Fig. 7-B, so as to conform to the location of the cam at the back of the lathe. This gages from the flange of the shell mandrel to the point of the shell.

A rough sizing gage for the nose is shown at B, Fig. 8. It is turned on the outside so that it will slip easily into the $1\frac{11}{16}$-in. hole already drilled, while the hole through the gage is a loose fit over the end of the shell mandrel. The looseness of this fit on the mandrel shows how much the shell can be jockeyed on the mandrel and still clean up on the inside. As long as this rough gage will go over the end of the work mandrel and into the shell nose, the bore of the shell has not been thrown out of center too much to be cleaned up. This instrument also serves another purpose, as the outside is used as a gage for setting the turning tool. It also avoids inconvenient calipering on the rounded nose and allows the operator to set his tool for the cut almost at random, as he cannot well set it to cut smaller than the outside of the nose piece.

Two Tools for Rough-Turning

Two tools are used in the rough-turning—one starting at the nose and the other about midway of the shell. They are held in independent tool slides on the carriage. One slide—the one with the nose tool—is controlled by the forming cam at the back of the lathe, as can be seen in the view in Fig. 7, which is taken looking straight down on the lathe.

This operation is also performed on a Root & Van Dervoort special lathe having the same type of headstock as the cutting-off machine. The main bearing in each case is 14 in. in diameter by $7\frac{5}{8}$ in. long, the rear bearing being 7 in. in diameter by $7\frac{1}{2}$ in. long. The same lathe

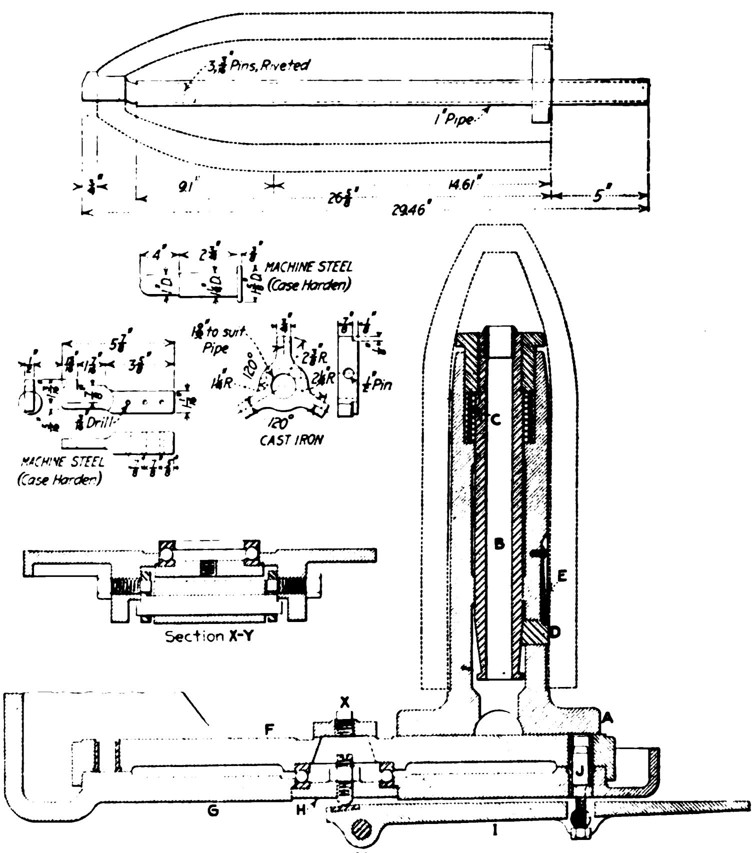

FIG. 5. DETAILS OF DRILLING FIXTURE AND GAGES

head is used for both the turning and the boring lathe, a special mandrel, Fig. 8, being bolted to the end of the hollow lathe spindle for the outside operations. The lathes for the internal work are fitted with special steel draw-in collets operated by air and fitting the turned shell.

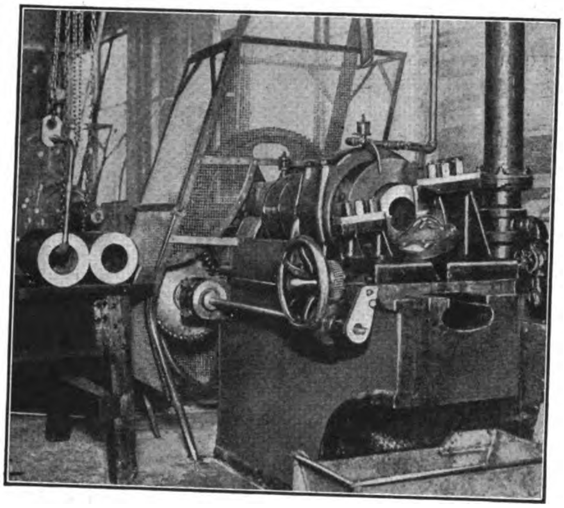

FIG. 6. OPERATION 2: CUTTING OFF OPEN END
Machine Used—Root & Van Dervoort special.
Fixtures—Chuck length stop and handling truck.
Gages—Length.
Cutting Speed—35 to 45 ft. per min.
Production—8 min. each.

Rough-boring comes next, the shell fitting inside the lathe spindle as in cutting off. A heavy boring bar made of a steel casting is used for this work, being guided for contour by the slotted cam at the back of the lathe bed. It is shown in Fig. 9, while details of the boring bar itself will be found in Fig. 10. Finish-boring is done in a similar manner on an adjoining lathe, the work progressing from one machine to the next, in order to reduce handling to a minimum, this being important on heavy shells.

Finish-turning is performed by a single round tool, Fig. 11, that is held stationary and turned only when it is desirable to present a fresh cutting edge to the work. This method gives a fairly broad contact and leaves a

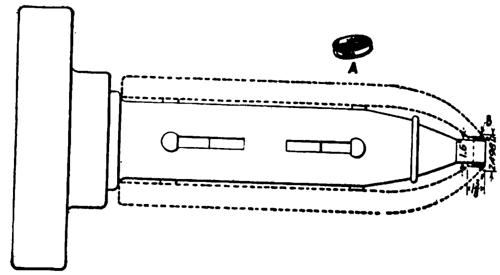

FIG. 8. DRIVING MANDREL FOR SHELL

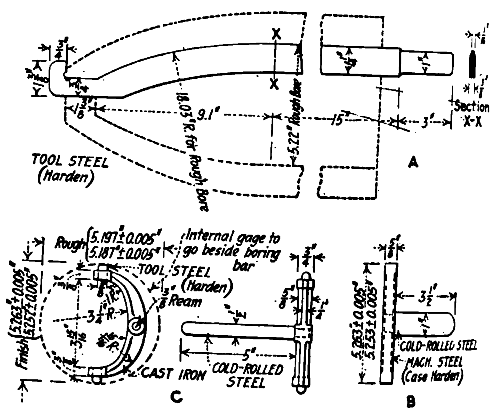

FIG. 9-B. GAGES FOR OPERATIONS 4 AND 5

smooth finish on the work. After the finish-turning, the heat number is stamped on the nose of the shell, so as to preserve it when the outer end has been faced off to length and to secure the specified weight.

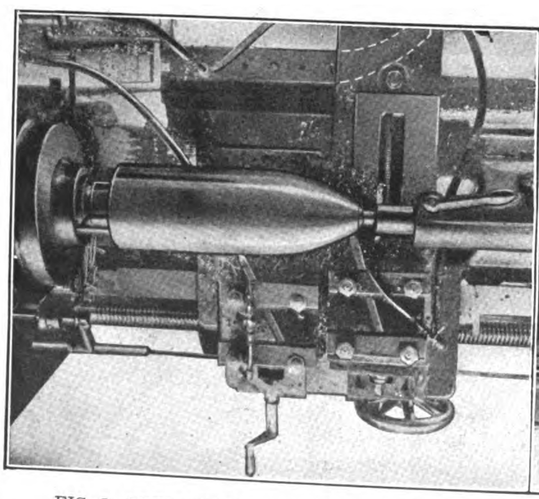

FIG. 7. OPERATION 3: ROUGH TURN OUTSIDE
Machine Used—Root & Van Dervoort special lathe.
Fixtures—Mandrel and forming cam for tool slides.
Gages—Snap for outside diameter; nose gage.
Cutting Speed—55 ft. per min.
Production—35 min.; expect to reduce to 25.

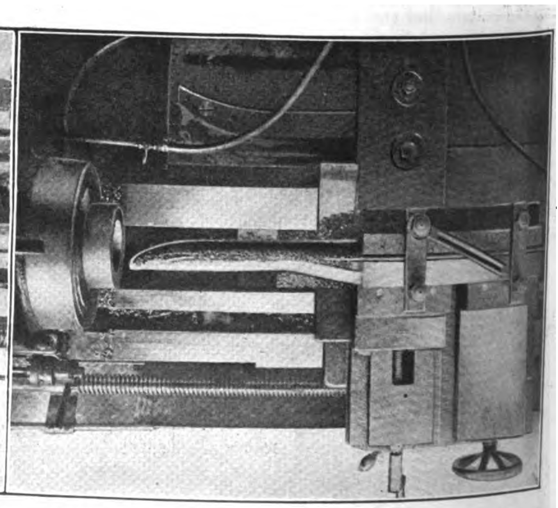

FIG. 9. OPERATIONS 4 AND 5: ROUGH AND FINISH BORE
Machine Used—Root & Van Dervoort special.
Fixtures and Tools—Boring bars and formers.
Gages—Diameter and contour.
Cutting Speed—55 ft. per min.
Production—25 min. roughing, 20 min. finish.

Boring and tapping the nose for the fuse were first accomplished in a special lathe having a similar headstock and a two-position cross-slide—one for the nose reamer and the other for the collapsing tap, as shown in Fig. 12—but are now being done under a Baker vertical drilling machine by changing the reamer and tap by means of a magic chuck.

Drilling and tapping for the fixing or grub screw comprise one of the vexatious operations on a shell of this kind. In the beginning a portable pneumatic drill was used, while the shell was held in the pot chuck, Fig. 13. The drilling bushing was held in the fixture shown at the top, and in detail at *A*, Fig. 14, the threaded plug screwing into the nose after locating the hole the right distance from the end of the shell. The details of the pot chuck for holding shells vertically are also shown. It can be used for holding the shell either end up, the ring *B*, bored to the proper curvature, forming a seat for the shell nose when the large end is up for screwing in the adapter plug. This prevents bruising the nose.

This method was a slow and unsatisfactory proposition and has been replaced by a sensitive vertical bench drill, the shells being rolled along until they come under the drill. This procedure is proving much more satisfactory, both for drilling and tapping, and has reduced the time and broken taps to a considerable extent. Continuous benches are used as much as possible throughout the shop, so that the shells can be rolled from one operation to the next. This has been used as an alternative to the trucking system in use in some shops and about which

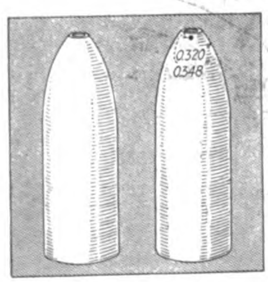

FIG. 13-A. OPERATION 8

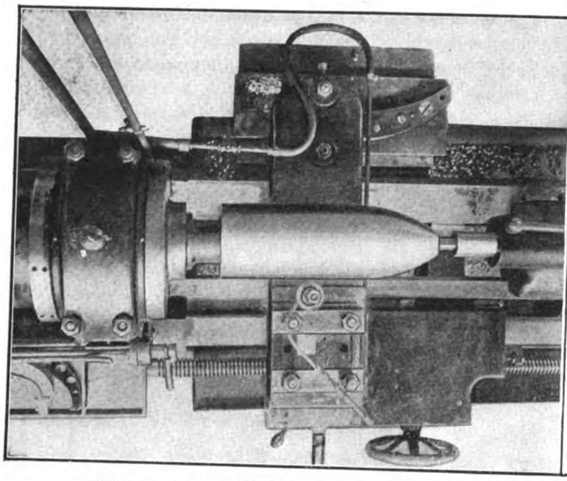

FIG. 11. OPERATION 6: FINISH TURN
Machine Used—Root & Van Dervoort special.
Fixtures and Tools—Mandrel, one round tool former.
Gages—Diameter and contour.
Production—30 min. each.

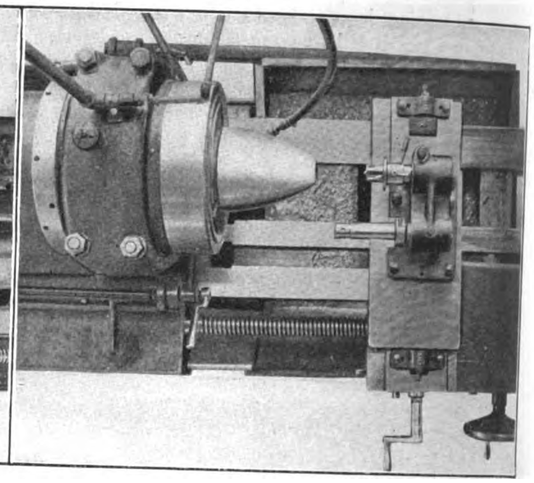

FIG. 12. OPERATION 7: BORE AND FACE NOSE
Machines Used—Root & Van Dervoort special, Boker drilling machine.
Fixtures and Tools—Collet chuck, Kelley reamer Murchey tap.
Gages—Diameter, thread and bevel surface.
Production—6 min. each.

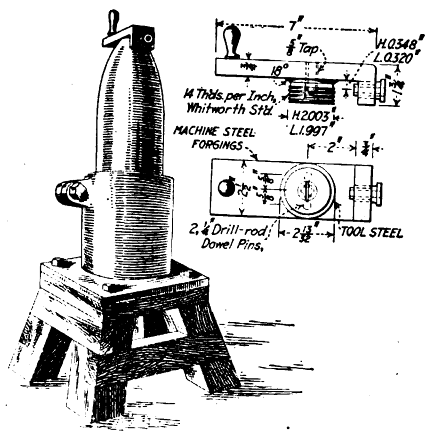

FIG. 13. OPERATION 8: DRILL AND TAP FOR GRUB SCREW
Machines Used—Portable drill and bench drill.
Fixtures and Tools—Pot chuck, drilling jig, drill and tap.
Gages—Location of holes, diameter and thread.
Production—3 to 6 min.

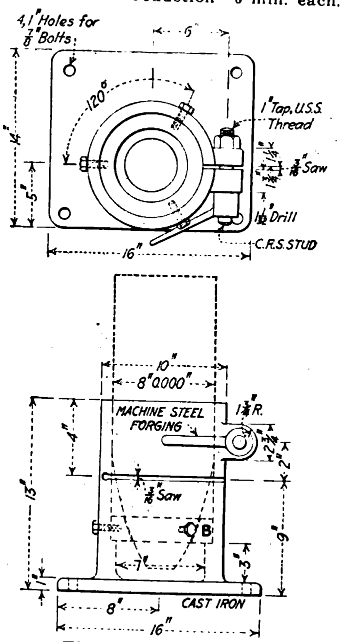

FIG. 14 DETAILS OF POT CHUCK

there is quite a difference of opinion. With lighter shells the truck system is probably the best, but with shells weighing approximately 200 lb. each, rolling saves considerable handling. And when handling means the clamping or placing of hooks or tongs, and then lifting the shell by mechanical means, the time required is by no means a negligible quantity. In fact the matter of handling 250,000 lb. of shells a week, and not only once but between every one of the many operations, is quite a problem in itself.

Special frames were made to hold these on the trucks, with divisions to keep them on end and separate. These were, however, abandoned in favor of the bench system. It saves considerable lifting at various stations and has proved very satisfactory.

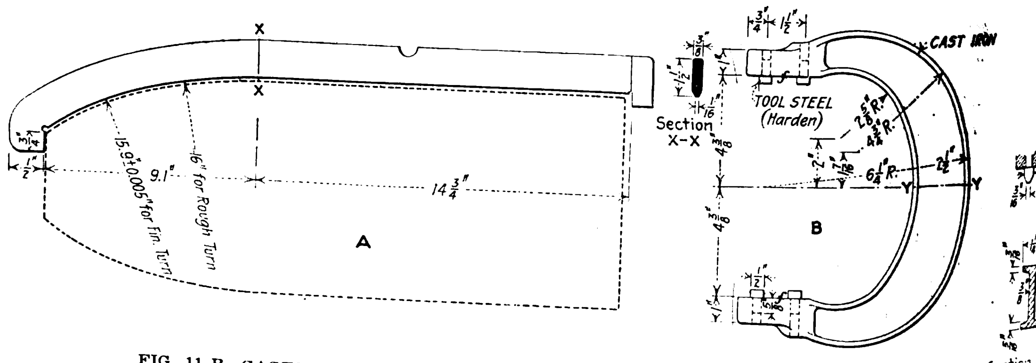

FIG. 11-B. GAGES FOR OPERATION 6, FINISH-TURNING THE OUTSIDE OF THE SHELL

Using Skill for Capital in the Small Shop

By John H. Van Deventer

SYNOPSIS—Doing what other people cannot do is one of the surest ways to success in the small-shop field. This article tells of a New England die-sinking shop that is making good on a line of work that requires a high degree of skill. How large-shop experience helps the small-shop owner to operate on sound and systematic lines becomes evident.

When you go into a successful small shop, you are often struck with the resemblance it has to a well-managed department of a large shop. Evidently there are certain earmarks of good practice that apply to small and large shops alike. Some of them, such as a clean floor, orderly and convenient arrangement of machines, proper cupboards for small equipment and tools, may be classified, inventoried and written down in plain figures; others are more vague and elusive, but can nevertheless be quite plainly felt by a shopman's sixth sense. Among these is the perception that the work is being handled to advantage, from both the customer's and the shop owner's viewpoints. Time study would paint this picture after a month or two—the sixth sense will do it instantaneously, like a "snapshot" photograph.

The small-shop owner who has had a part of his training in a large shop is somewhat ahead of the game, having obtained his education in an institution richly enough endowed to be able to find better ways of doing things by experimentation, as distinguished from the small-shop man "brung up" in the small shop, who must cut his eye teeth without the aid of a dentist. And so when the ex-large-shop man starts a small shop he is apt to carry in his mind the memory of the large-shop department and its way of doing business.

The large-shop idea is evident in the small shop of Hollander & Johnson, Worcester, Mass., who specialize in drop-forge die sinking. At present some seventeen men are employed in this shop, which is a rather rapid growth from a two-man beginning made three years ago. To some extent the demand for drop-forge dies for munition making has been responsible for this enlargement; but the start in the right direction was independent of this condition, and it is the start that will interest other small shops having a large capital of skill and a small capital of cash.

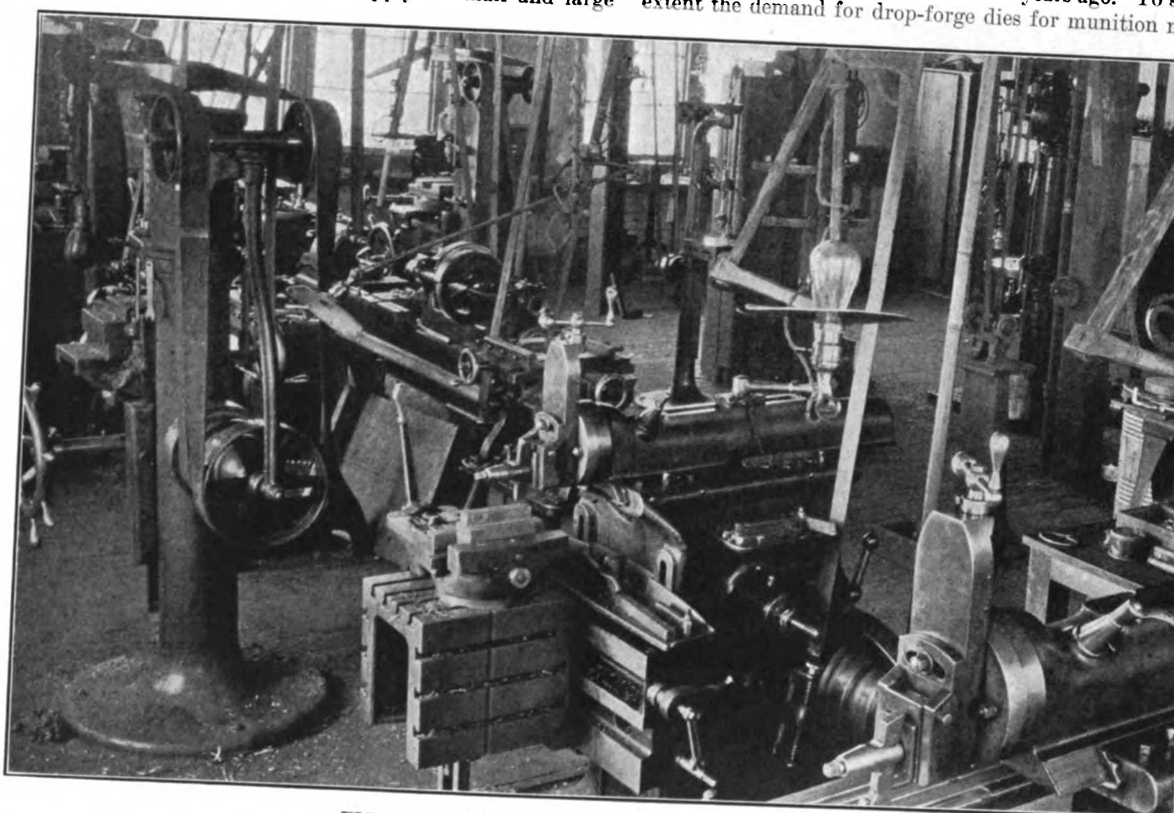

FIG. 1. A THREE-YEAR-OLD DIE-SINKING SHOP

A shop struggling for a start cannot pick and choose the class of work that it does. Often the crucial test comes in the shape of an order for work that is apparently unsuited to the machine tools at hand. In this case it was an order for 450 sets of molds for making rubber shoe-soles. There were two machines available for this work—a shaper and a die sinker—in fact, with the addition of a lathe they comprised the entire shop equipment. Taking

The order for these 450 molds for delivery in 6 weeks took both nerve and hard work; but the task was accomplished by operating night and day, and doing it put the small shop on its feet—one might say a pair of rubber-soled ones!

S. G. Hollander obtained his large-shop experience in drop-forge dies at the United Shoe Machinery Co.'s plant

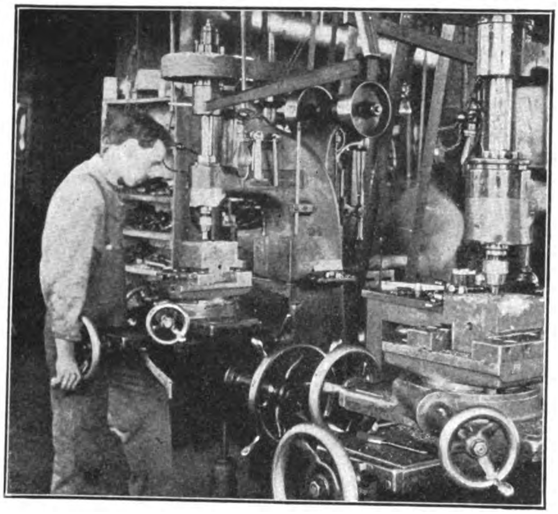

FIG. 2. SINKING RIFLE BOLT DIES

at Beverly, Mass., where he had charge of this class of work, both as to making the dies and using them. He has retained one very important large-shop feature in the making of such things—the division of labor according to the degree of skill required. Some small die-making shops are run on the old toolroom basis, one skilled man traveling about from machine to machine and taking care of the job from start to finish. The large-shop method is to pass the work from one man to another, each one a specialist on his own machine or bench, and this scheme is applied in the small shop to good advantage in both time and money.

The properly run small shop can take work requiring a high grade of skill at very nearly the cost-to-make in

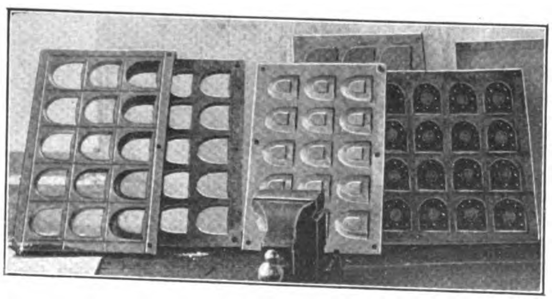

FIG. 3. MOLDS FOR MAKING RUBBER HEELS

the big-shop toolroom and come out with a profit. Here lies one of the big weapons of the small shop in hunting for business, and it is due to the low overhead expense as compared with the high one in the big plant. A shop of fifteen to twenty men, in which the owner is superintendent and manager, correspondent and time clerk, as well as on frequent occasions a die maker or tool maker, will show up an overhead of from 15 to 25 per cent., as compared with the 100 to 150 per cent. of the big shop. If this fact is thoroughly mastered, it will open up new business for the small-shop man who grasps it and uses it as a selling argument.

Another feature that will result in business is to relieve the large shop of responsibility and detail. Some people cannot get enough responsibility to suit them, but the real big fellows have a habit of placing it on other shoulders than their own when they make sure that these shoulders are broad enough to carry it. The small-shop man with small views is apt to pin the responsibility as closely to his customer as he can, living up strictly to his blueprint. The small-shop man with big views goes at it another way, saying: "Show me the piece you want made and the machine on which you want to make it and leave the rest to me. I will be responsible for the result." It

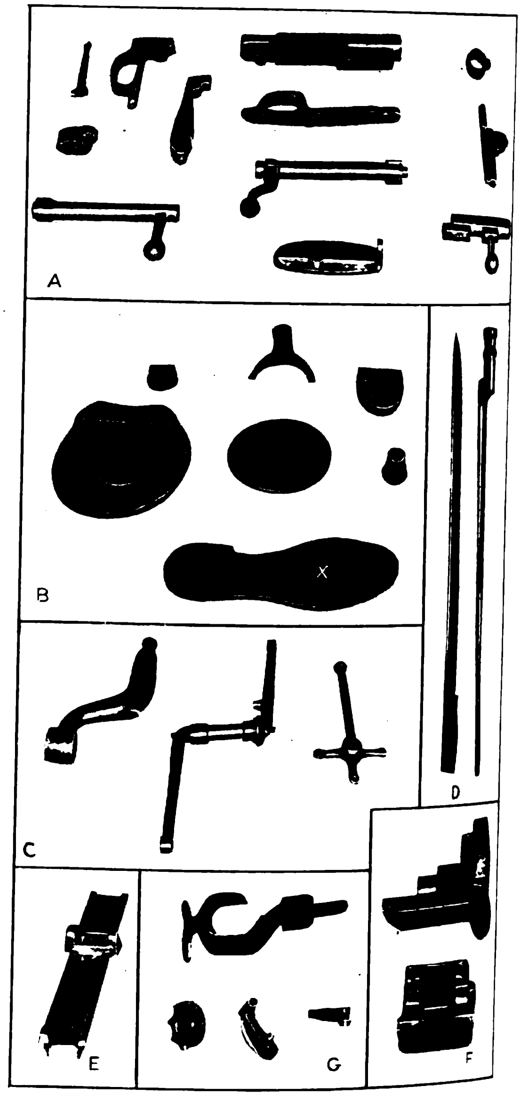

FIG. 4. ARTICLES PRODUCED IN SMALL-SHOP MADE DIES

A—Military rifle forgings; B—Rubber die products; C—Auto and bicycle forgings; D—Bayonet forgings; E and F—Machine-gun forgings; G—Miscellaneous

is unnecessary to say that this is a strong argument with a busy executive who is buried up to his chin in responsibility and who is glad to place some of it elsewhere on favorable terms.

The illustrations reproduced on these pages show what progress a two-man three-machine small shop can make in three years. It was done by hard work and skill and with no outside capital and should encourage other small-shop owners who have plenty of the former and not much of the latter.

Steel Famine in Japan and Its Effect on Shipbuilding

By a Japanese Engineer

Since the war in Europe broke out, industry in Japan has expanded wonderfully, though not so much as in the United States. This is especially true in shipbuilding. As an example, the Osaka Iron Works have orders in hand at present for a tonnage exceeding that of all the ships which they have built during the last 35 years, or since they started in that kind of business. Besides, all sorts of engineering works, for both peace and war, are in full swing and being extended. This situation makes it interesting to study the question of raw material—namely, iron and steel—for these works.

When the war began, the supply of steel from England was affected to some extent, and this condition became more serious when the Munitions Act in that country went into force. Later on, the greater activity of the submarines in the Mediterranean Sea made it worse. Beside that, the declaration last fall, of the American Steel Trust that it would not accept any new orders until further notice was a great blow to many engineering works. This fact is shown by the following table of steel material ordered from abroad. The amount, even for shipbuilding alone, allotted for vessels to be completed during 1916 is estimated to be 75 per cent. of the whole weight, 50 per cent. of this proportion being from the United States.

The steel for shipbuilding, for ships to be completed during 1916, is estimated as follows:

Ordered from	Tons	Approximate Percentage
British Isles	22,690	25
United States	44,880	50
Home	23,704	25
Total	91,274	100

Of these orders the material from Great Britain is mostly bars and section, while that from the United States is in plates. According to the latest news from England, the mills are busy drawing bars for munition works, the result being the suspension of output of bars and sections for Japanese shipbuilding, though it is said that it will be possible to resume this work in the near future.

Production of Japanese Steel Works

Such being the case at present, it is quite natural that all users of iron here go to the home steel works, asking for more and more turn-out, though at the same time they do not neglect any means for getting steel from abroad as well. The capacity of the home mills is as follows, the Government steel works being the largest one in this country and all private firms being quite small:

	Tons per Year
Rolled-Steel Capacity:	
Government steel works	290,000
Tanaka Steel Works, Kamaishi	30,000
Total	320,000
Pig-Iron Capacity:	
Tanaka Steel Works, Kamaishi	40,000
Wanishi Steel Works, Hokkaido	20,000
Honkeiko, Manchuria	40,000
Total	100,000

On the other hand, the imports of raw material during the past three years have been as follows:

	Tons 1912	1913	1914
Pig iron, spiegel iron, ferromanganese, ingots, blooms, etc.	238,400	279,817	178,639
Bars, sections, plates, wire tubes and pipes, building material	612,409	548,172	436,113
Nails, anchors, chains, wire rope	54,903	29,842	18,301
Total	905,712	857,831	633,053

Taking the amount in 1912, which is the highest figure, and comparing it with the largest turn-out of the Government steel works—227,300 tons—which was in 1914 (the output in 1912 and in 1913 being 204,005 tons and 212,816 tons respectively), we get:

	Imports, 1912, Tons	Turn-Out of Government Steel Works, 1914, Tons
Plates, including checkered plates, corrugated plates, galvanized sheeets and plates, tin plates	155,548	47,505
Sections and the like	185,000	68,064
Rails	59,100	68,732
Nails and wire, including bands and hoops, wire rope, galvanized wire and railway nails	45,672	29,216
Others	84,680	13,783
Total	530,000	227,300

The item of imported plates in 1912 included:

	Tons
Corrugated plates	220
Galvanized plates and sheets	34,000
Tin plates	26,500
Total	60,720

These products cannot be made in Japan at all. Deducting this amount from 155,548 tons, it leaves 94,828 tons, which is approximately twice the capacity of the Government steel works—47,505 tons. The rails are the only item in which the amount imported is less than the home product. The turn-out of the Tanaka Steel Works was not taken into account in the summary given, as their exact figures are not available. Since that plant makes miscellaneous varieties, this omission will not affect the comparison to any large extent.

Comparing Past and Present Imports of Pig Iron

Pig iron was imported to the amount of 270,000 tons in 1912, this being 27 times the home product of 100,000 tons. These figures of comparison of the past, combined with the present crisis brought about by the shortage of steel and iron, naturally induced many new firms to start in business and caused the extension of existing firms. These projects number about 18 up to the present. Figures obtainable are as follows:

1. Government Steel Works—An addition in course of construction during the past few years will be completed early this year. The total capacity will be increased to 350,000 tons per year. Besides, a program will be submitted to congress in a few weeks, asking for an extension to cost 36,000,000 yen (2 yens = \$1, approximately) and to be finished in five years, beginning in April of

this year. An additional capacity of 300,000 tons per year will thus be provided, bringing the total to 650,000 tons per annum. If congress approves, the extension will be executed in such a manner as to add 50,000 tons' capacity at the end of the first year and another 50,000 tons at the end of the second year, for the purpose of relieving the urgent demand. At the end of the fifth year the total additional capacity of 300,000 tons will be reached.

2. The Tanaka Steel Works, the Lumitomo Steel Works (Osaka), the Kobe Steel Works and the Kanasaki Shipyard (Kobe), the Nippon Steel Tube Co. (Kanasaki), the Nippon Steel Works (Hokkaido), the Kuhara's Steel Works, the Kinjiho Steel Works (Chosen), etc., are contemplating extensions, or new plants. I estimate that when this construction work is completed—in perhaps four or five years—about 100,000 tons will be turned out by these firms.

3. The Honkeiko Iron Works report that they will treble their capacity of pig iron after a few years, adding, say, 80,000 tons to their present capacity.

Estimated Output in Five Years

So after four or five years the total product of rolled-steel material will be 880,000 tons, as compared with a consumption of 757,300 tons—the total of the imports of 1912 and the home turn-out of 1914.

Pig iron will reach to about 200,000 tons, compared with a consuming power of 370,000 tons. Thus, it is seen that there will still be a great shortage of iron and steel material in Japan. In view of the naturally great demand for steel building and machinery, I wonder if it is not a chance for American steel makers, who must be thinking of what they are going to do when the great European War comes to an end.

Turning again to the shipbuilding problem of Japan at present, we find such facts as that a ship 35 years old was recently sold at a price of 130 yen per ton. Last year the ownership of a 3,200-ton steamer that was to be completed in February, 1916, was transferred into other hands at a price of 70,000 yen, while she was still on the shipway. Moreover, a similar vessel, which is to be finished in April of this year, was sold at a price of 150,000 yen. These incidents show how scarce ships are in Japan just as everywhere else.

The whole number of ships with a tonnage of over 1,000 tons now in the shipyards of Japan is 88—a total of 481,000 tons and 292,680 i.h.p., including 20 stock boats of 172,800 tons total. Of these 88 ships, 40 (totaling 160,000 tons) will be finished during this year, while most of the remaining 48 ships are intended to be delivered during next year; but it all depends upon whether the supply of steel necessary from abroad comes in time or not.

It is interesting to notice that the net weight of the ships when turned out from the shipyard, without water and consuming material (usually called light displacement), is about 60 per cent. (strictly speaking, a little less in a pure cargo boat). As the cargo-carrying capacity of a ship is slightly less than twice the gross tonnage, it may be said that one ton of ship will be able to carry about three tons of cargo. In other words, every ton of ship that costs approximately 300 yen will earn about 450 yen interest per year at present rates.

The Imperial Government Railway, which controls nearly all railroad lines in Japan, used to get 100,000 tons of steel per annum from the Government Steel Works, including rails, nails, etc., besides the greater amount obtained from abroad. Lately the railway office has demanded a supply of 70,000 tons as a minimum quantity for this year. The Government Steel Works, however, have declined to supply more than 40,000 tons, which means the practical stoppage of any new work, as well as the use of wood in place of steel, wherever possible. This will delay the introduction of steel cars on Japanese railways.

The engineers' society at Osaka is proposing to the Government Steel Works to buy a great amount of steel material of several varieties from the United States, as stock, but it is doubtful whether this will be done.

The First Cleveland Automatic and Its Development

Special Correspondence

An interesting contrast, which indicates the development of one of the best-known automatic screw machines in this country, is illustrated herewith. The first machine shown was built in the toolroom of the White Sewing Machine Co., Cleveland, Ohio, 28 years ago. It was designed for producing brass washers for sewing-machine bobbins, its only work being confined to forming, as the drilling of the washers was a separate operation. The tools for forming the washers were mounted on an

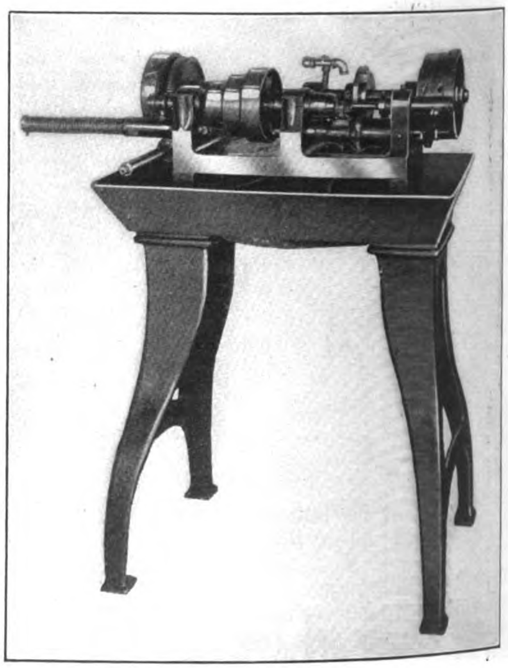

FIG. 1. THE FIRST CLEVELAND AUTOMATIC

oscillating tool post, which swung forward for the forming tool and swung back for the cutting off.

The regulation three-step cone was used on the main spindle, which means that only one speed was available without moving the belt by hand. The mechanism on the inside of the cone for opening and closing the chuck would be considered old-fashioned and bothersome today.

on account of the large number of parts liable to be disarranged. Considering the fact, however, that this machine was built 28 years ago, it worked quite satisfactorily.

Its success was responsible for continuing with the automatic idea, and this machine was in reality the foundation of the Cleveland Automatic Machine Co. of today, which built it with no thought of ever going into the machine-building business. Six of these automatics

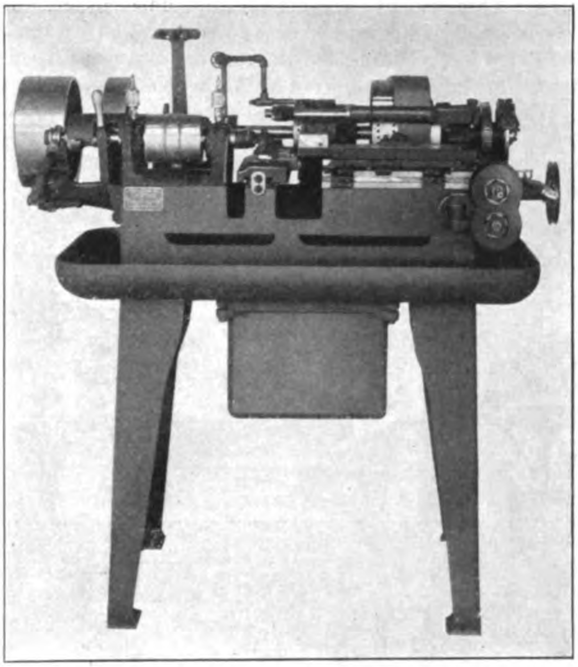

FIG. 2. THE DEVELOPMENT OF 28 YEARS

were first built—of ⅝-in. capacity—as a beginning of the automatic-machine business, about 26 years ago.

It is interesting to notice both the difference and the similarity between the original and the present machine, the most striking difference being that the speed of the camshaft can now be changed for various kinds of materials and jobs by means of changed gears. A series of tools can be mounted on the longitudinal slide so as to produce several shoulders. The gage stop is separate and independent. Independent cutoffs and the use of double cross-slides enable interesting operations to be performed on a plain automatic, which was not originally the case. The real similarity ends with the appearance, as while the old machine was designed for forming the simplest kind of machine parts, the other is suitable for the many operations demanded of a modern machine.

Sponges That Only Absorb

By John R. Godfrey

They say it takes all kinds of people to make a world, but my own opinion is that we have a plentiful supply of several kinds for some years to come. One of these is the sort of sponge that is perfectly willing to absorb all the information he can find, but refuses on one pretext or other to give up any in return. There aren't so very many of this breed, but they still exist.

My friend Bill Johnson, got into the shell game pretty early and had all kinds of trouble, till he got on to a lot of the curves of both the shells and the inspections. He didn't make any bones of it either and naturally felt a bit proud when he'd found the bugs and killed 'em.

Bill was traveling not long ago and ran on to another fellow from out in the Middle West, who was just starting in the same game and was having his troubles, same as most of 'em do. Well, Bill opened up and told him how he'd crawled under some difficulties and climbed over others; and as the Middle Westerner was going to be near his town, Bill asked him to come over and see things.

Mr. Middle Westerner comes all right and spent a day, Bill giving him as much time as he could and letting him nose around by his lonesome the rest. Oh, but he was grateful—any time Bill wanted any dope in M. W.'s line, all Bill had to do was to holler, and a lot more taffy that Bill set down to natural exuberance or such.

Now it so happened that Bill went West not so very long after and thought he would blow in on Mr. M. W. and see how he was getting on. Bill dropped a line to say he'd be in on the 2:15 train and kinder half thought Mr. M. W. might be there with his car to drive him out. But the M. W. wasn't, and that isn't all. Bill found his way out to the place, way backside of nowhere, with dirt roads and no sidewalks. He caught a glimpse of the M. W. when the latter didn't know it and so was a bit surprised to be told he wasn't in. But Bill nailed him at last and was rewarded with the information that it was strictly against the rules for anyone to go into the shop. Sorry, but he couldn't make any exceptions and other bunk.

I'd like to write what Bill said to Mr. M. W. when he got over the shock, but the censors would stop the edition, even if the editor shut his eyes when it went by.

But after passing the M. W. a few complimentary remarks about being a hypocritical, ungrateful cuss in general, Bill read the riot act on the principle of the whole thing. He pointed out in polite but forcible language that he had given a lot of his time, all his experience and saved M. W. a barrel of money in experimenting. Then he showed that man what a low-down, lop-sided sort of a hound he was to grab all he could from others and not give back to the general fund of mechanical knowledge.

Then Bill spotted the *American Machinist* reprints on shrapnel and high-explosive shells, and he broke out in a fresh spot. Showed how such information was made available because most manufacturers were openminded enough to realize that the whole advance in mechanics was due to an interchange of ideas—that the fellow who didn't give out his mite was reniging in the game and had a soul about the size of a plugged nickel. Said that if M. W. wouldn't add his bit of real dope he ought to be man enough not to use the other fellow's stuff and that there ought to be some way whereby he could be prevented from buying any of the papers which give other methods.

Bill came home mad clear through—wouldn't have hurt him so much if it had been somewhere else besides the "open-hearted West"—that's what got his goat the most, and it isn't altogether strange is it?

As Bill says, he don't blame anyone in the war game for not saying much till he gets what orders he needs; but when he's got things cinched, he sure ought to give up for the general good.

I'm wondering if Bill's scheme for an embargo to prevent the *American Machinist* from reaching men who won't give up their end of the game isn't a good thing.

Jigs Used for Machining Parts of a Press Feeder

By Robert Mawson

SYNOPSIS—Because of the high speed at which the feeder operates and the necessity for interchangeable manufacture, these parts must be accurately machined. In most cases when the part is milled the drilling operation is the next in sequence. This routine enables the part to be either located or placed on finished surfaces.

The two-sheet rotary printing press illustrated on page 58 is manufactured by the United Printing Machinery Co., Woonsocket, R. I. Several articles have already appeared, showing and describing examples of jigs and fixtures employed in machining elements used on the press. These tools were examples of economical and successful small-tool construction, and equally well designed tools used in machining five other parts used on the feeder for the press form the subject of this article.

Where rough surfaces are used for locating, adjustable means, such as screws, are provided so that the locator may be easily changed as conditions demand. The operations on all of the parts consist of drilling and reaming.

JIGS USED IN MACHINING PRESS-FEEDER PARTS, WITH WORK SHOWN IN POSITION

FIGS. 2 AND 2-A

Operations—Drilling and reaming upper center bearing, Fig. 1. The milled casting is located against two pins, being forced back with knurled-head screws, as A. The cover is then dropped down and held with the three thumb-screws shown. The three screws B are then tightened down and hold the casting in position.

Holes Machined—One $1\frac{15}{64}$-in. drilled and reamed $1\frac{1}{4}$ in., one $\frac{63}{64}$-in. drilled and reamed 1 in., three $\frac{47}{64}$-in. drilled and reamed $\frac{3}{4}$ in., one $\frac{31}{64}$-in. drilled and reamed $\frac{1}{2}$ in., three $1\frac{7}{64}$-in. drilled and reamed $1\frac{1}{8}$ in., one $\frac{55}{64}$-in. drilled and reamed $\frac{7}{8}$ in.

FIGS. 4 AND 4-A

Operations—Drilling and reaming pile drag carriage bracket, Fig. 3. The milled casting is located by ears which are set on the inside of the machined surface of the fork end. It is forced back with a knurled-head screw at the opposite end. The cover is then dropped down and fastened with the thumb-screws A. The setscrew B is tightened down on the casting and holds it securely.

Holes machined—One $\frac{55}{64}$-in. drilled and reamed $\frac{7}{8}$ in., one $\frac{49}{64}$-in. drilled and reamed $\frac{5}{8}$ in., one $\frac{63}{64}$-in. drilled and reamed 1 in., one $\frac{5}{16}$-in. drilled and one $\frac{3}{16}$-in. drilled.

FIGS. 6 AND 6-A

Operations—Drilling and reaming lower conveyor bracket, Fig. 5. The rough casting is located by a V-block inside of which the circular boss of the part is forced, with a setscrew at the opposite end. A setscrew on the under side forces back the piece against locating pins.

Holes Machined—Four $\frac{39}{64}$-in. drilled and reamed $\frac{5}{8}$ in., two $\frac{47}{64}$-in. drilled and reamed $\frac{3}{4}$ in., one $\frac{63}{64}$-in. drilled and reamed 1 in., one $\frac{3}{16}$-in. drilled and two No. 9 drilled.

FIGS. 8 AND 8-A

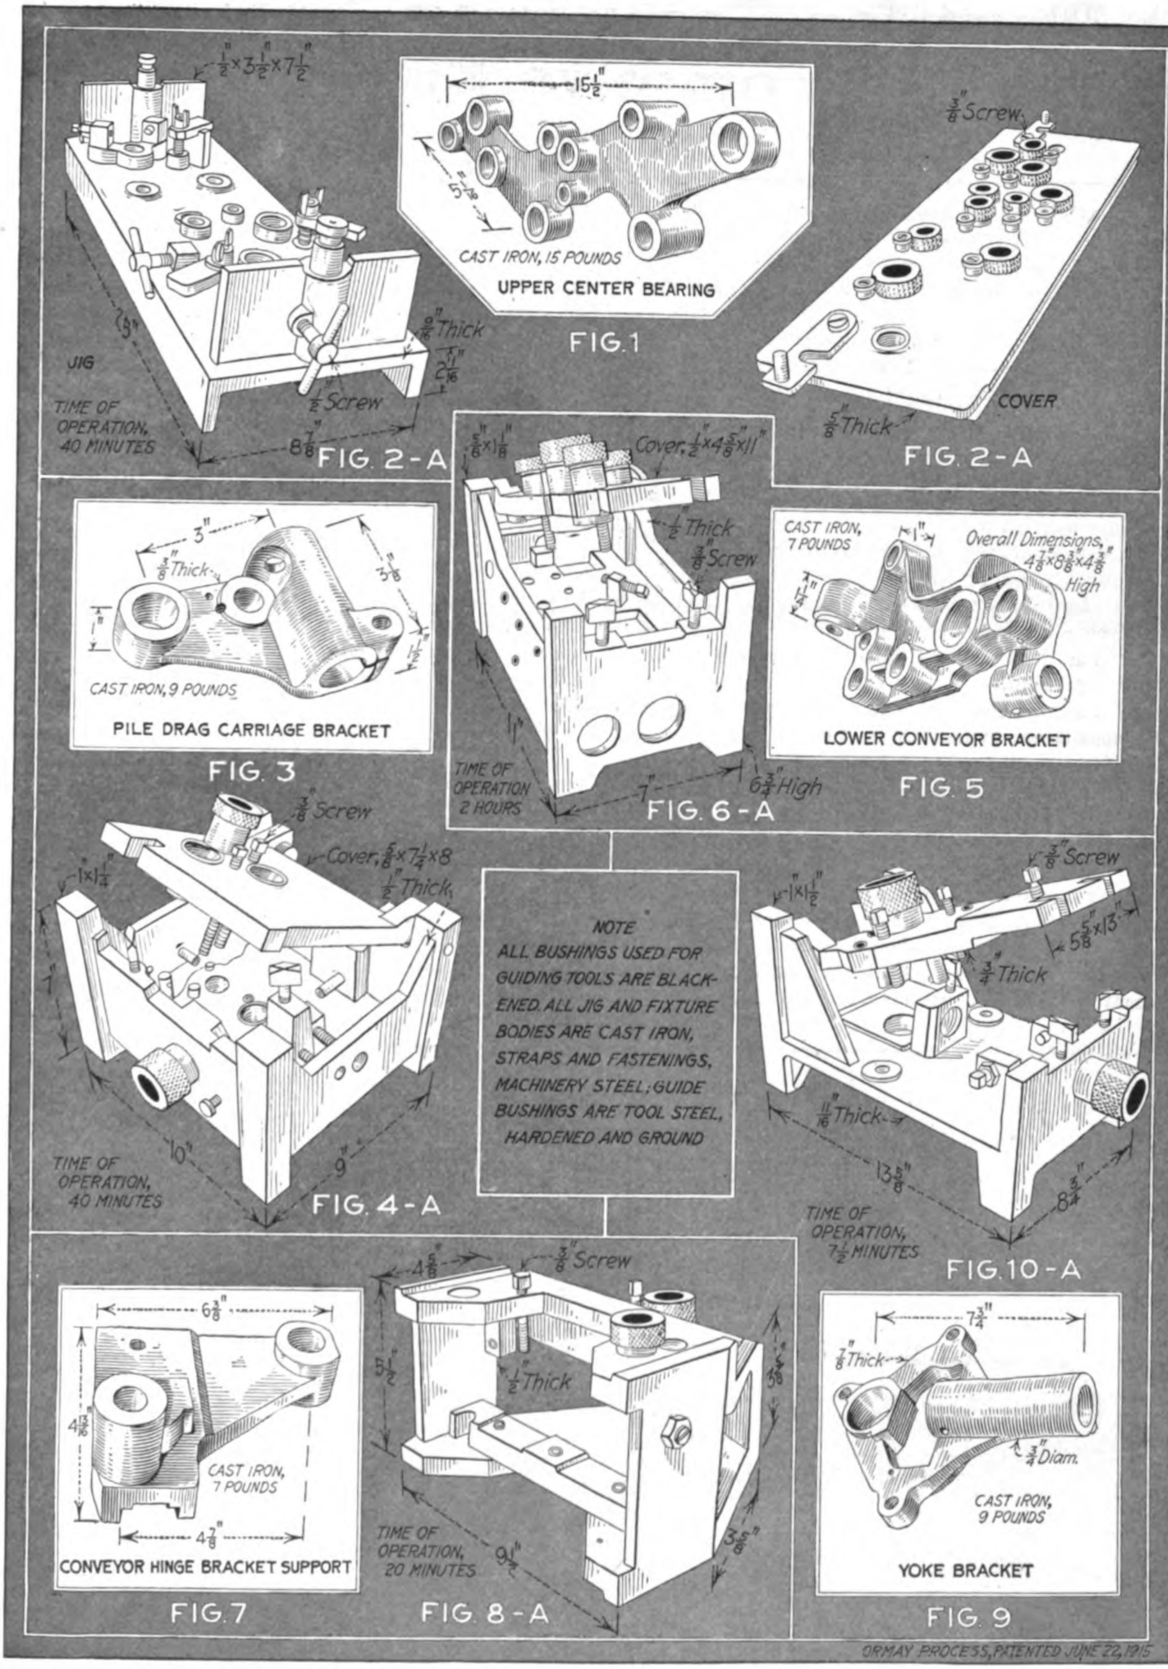
Operations—Drilling and reaming conveyor hinge bracket support, Fig. 7. The milled casting is located over a machined block and forced into the correct position determined by the adjustable setscrew A with another screw. The cover is then dropped down and fastened with the thumb-screw, as shown.

Holes Machined—One $\frac{55}{64}$-in. drilled and reamed $\frac{7}{8}$ in., one $\frac{39}{64}$-in. drilled and reamed $\frac{5}{8}$ in. and two $\frac{5}{16}$-in. drilled.

FIGS. 10 AND 10-A

Operations—Drilling and reaming yoke bracket, Fig. 9. The milled casting is located by a stop pin at one end and forced against the adjustable setscrew A with a screw at the other end. The cover is then dropped down, fastened with the three thumb-screws, and the setscrews B are tightened on the casting, thus holding it securely.

Holes Machined—Two $1\frac{15}{64}$-in. drilled and reamed $1\frac{1}{4}$ in. and three $\frac{7}{16}$-in. drilled.



DETAILS OF JIGS USED IN MACHINING PRINTING-PRESS FEEDER PARTS

A Plant for Conversion From Rifle to Locomotive Building

EDITORIAL CORRESPONDENCE

SYNOPSIS—The main interesting feature of this plant is the fact that it was designed primarily for building locomotives and is yet capable of being temporarily converted to the manufacture of rifles. The wide difference in products and in methods makes such a building construction of unusual interest. The completeness of the oil-reclaiming plant, covering as it does both chip and waste, is also unusual in size and equipment. It reclaims both the oil and the waste.

It is decidedly unusual to speak of a huge manufacturing plant as a byproduct, and yet that is exactly the character of the new buildings of the Baldwin Locomotive Works at Eddystone, Penn. Several years ago the company purchased a large tract of land, with the purpose of ultimately moving its huge locomotive works from the heart of Philadelphia to the new site, and a few buildings were erected as the beginning of the change. In common with many other unexpected developments due to the war the need of manufacturing plants for immediate use furnished the opportunity of preparing buildings for practically the entire plant at most advantageous terms.

A contract was entered into with the Remington Arms Co. of Delaware for the erection of these huge shops and their use during the manufacture of large orders of rifles for the contending armies. Plans were made so that the buildings erected should be eminently suited for the manufacture of locomotives, but should temporarily be converted into shops for rifle manufacture. These conditions developed a type of buildings, as illustrated in Fig. 1, that are capable of considerable interior modification, either temporarily or permanently, to adapt them for various kinds of work.

There is nothing temporary about the construction of the buildings themselves, which are of the most modern type, laid out to secure the best use of the land available.

The flooring arrangement has been put in with a special view to the manufacturer of rifles, but can be readily altered at any future time or even entirely removed from the central bays in shops where the nature of the work may make it seem desirable to do so. The general construction may be said to be of tile and steel, with a view to making the plant thoroughly fireproof.

The plant covers 15 acres of ground and was erected in record-breaking time—about 3 months. The main building is 1,040 ft. long by 816 ft. at the widest part. The buildings, with the temporary flooring, give a total floor area of nearly 38 acres. The main building has 13 aisles and 341 bays, each 24x80 ft. Four towers, 80x48 ft. and 74 ft. high, provide spaces for three hydraulic motors in each, when locomotive boilers are to be made. Three cranes will go in each tower to handle the boilers being riveted.

Every effort is made to secure a maximum amount of light, and in addition to the light from glass in the roof the outer walls have as large windows as are possible. To conserve still further the effective lighting, the sections with one or two auxiliary floors are alternated with single-floor bays.

It will be noticed that the building is not of uniform ground plan, but that the width increases in steps. This

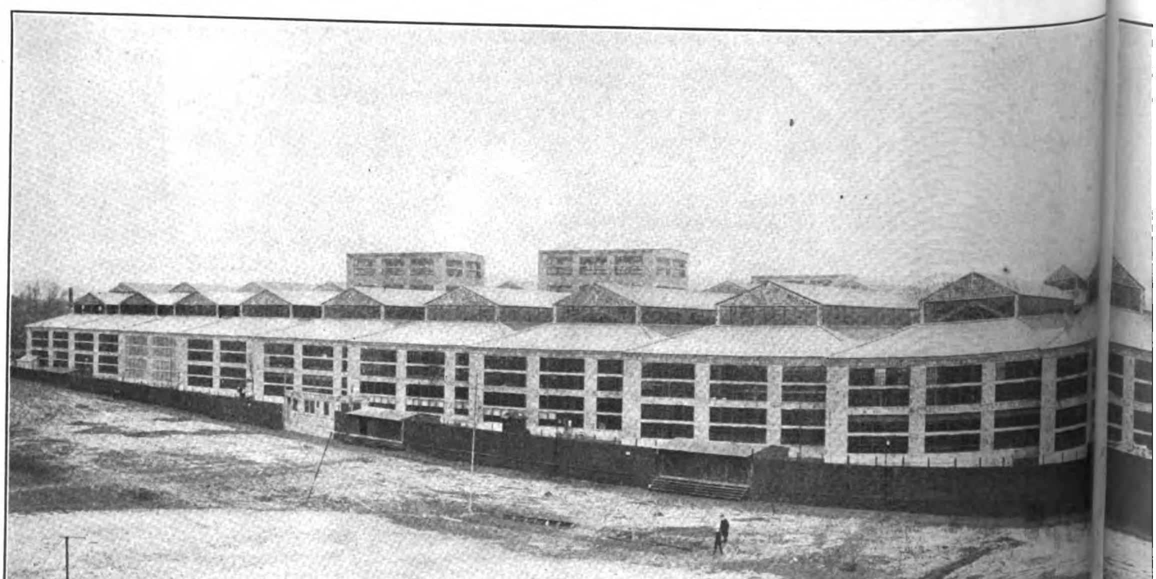


FIG. 1. A GENERAL VIEW OF THE NEW SHOPS ERECTED FOR THE ULTIMATE USE OF THE BALDWIN LO

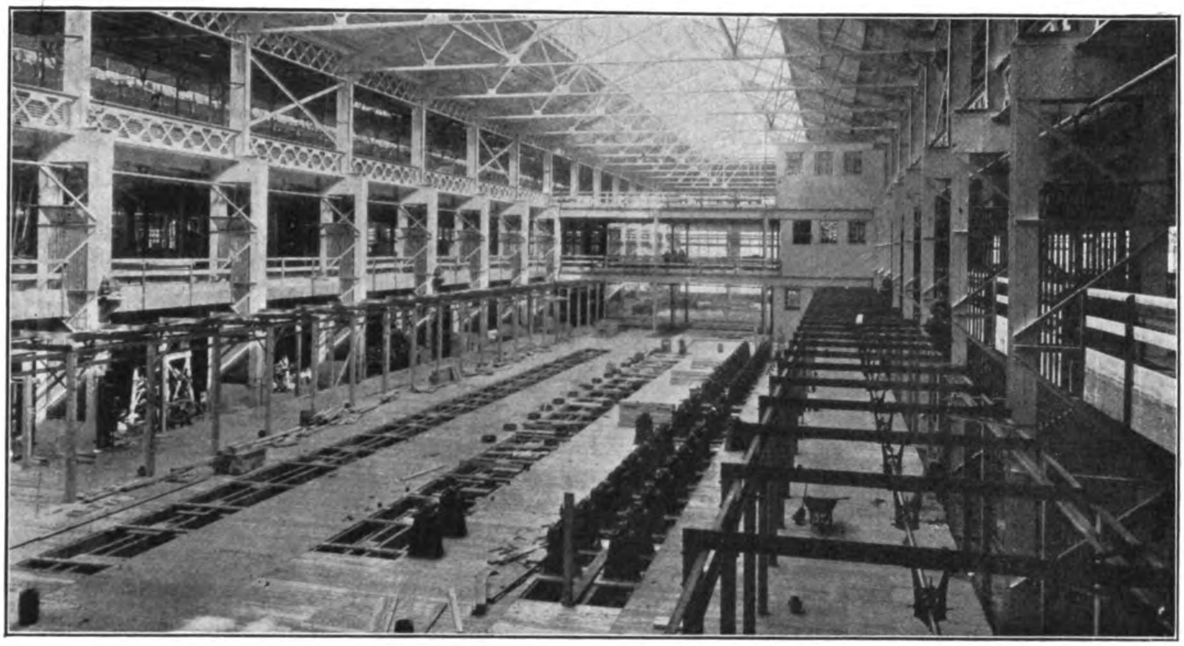

FIG. 2. A BAY WITH NO TEMPORARY FLOORING

arrangement gives entrance for a track at each step on each side of the building and allows all material to enter and leave at the sides, being transferred by traveling cranes wherever needed.

Power comes from the Philadelphia Electric Co. at 13,000 volts and is handled in three transformer houses that deliver it at 440 volts, 3 phase, 60 cycles. Five thousand kilowatts will be used.

The size of the work made a blanket contract out of the question, and the unit plan was adopted. The McClintock-Marshall Co. took the steelwork and employed all its own facilities in addition to subletting a portion to the Fort Pitt Bridge Co. The grading, foundation and concrete work was given to one firm, and other items were handled in the same way.

Fig. 3 shows a ground plan of the plant layout and gives some idea of the immense area covered by it. Only a few of the principal dimensions are given, but these will serve to show the size of the plant.

Figs. 2 and 6 are different interior views of the plant, the first giving a good idea of one of the bays that has been left free from intermediate flooring. The temporary line and countershaft structure is shown at each side, while a row of grinding machines occupies a

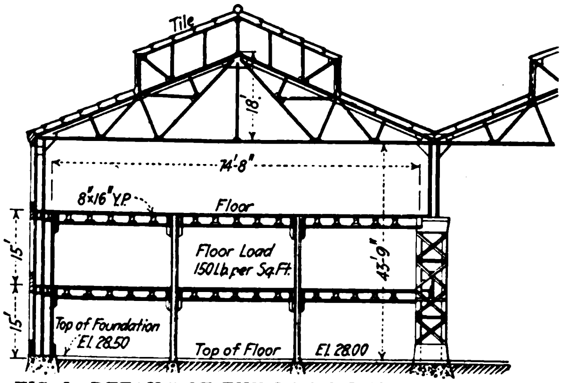

FIG. 5. DETAILS OF THE DOUBLE-FLOOR INSERTION

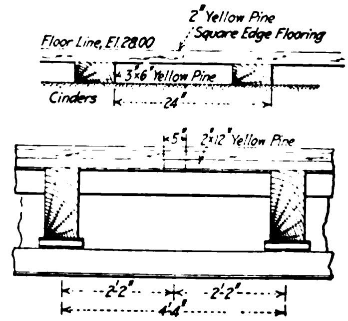

FIG. 6. FLOORING DETAIL

prominent place near-by. They are driven by shafting beneath the floor, the belt coming up inside the grinder column, as in modern practice.

Figs. 4 and 5 illustrate sections of the 80-ft. bays with the flooring in place. As will be seen, there are two styles—one being 43 ft. 9 in. to the bottom of the roof girder and carrying two floors with a headroom of nearly 14 ft. and intermediate columns that give practically a 25-ft. column spacing. The lattice girders supporting the ends of the roof trusses will carry rails for craneways, if the floors are removed and the shops used for handling large work. A portion of the buildings is only 30 ft. to the bottom of the roof girders. These sections are used with but one temporary flooring in place, but are otherwise very similar to the construction shown in the other view. A construction detail is shown in Fig. 6.

A view in the drop-forging plant is seen in Fig. 7, where numerous furnaces are shown in the foreground; the drop hammers are in the adjoining bay. This illustration also gives a good idea of the general building construction, particularly the lattice columns that support the roof and will eventually carry the rails for the craneway.

One of the most interesting features is the oil-reclaiming plant, which was designed by the plant engineer, B. T. Converse. Although this oil-reclaiming plant occupies a comparatively insignificant area as compared with the whole, it is in reality quite a fair-sized structure, about 26x70 ft. and approximately 20 ft. high. This building is of reinforced concrete throughout, with standard fireproof doors in every case, the window sash being of steel fitted with wire glass. In other words, it has been made as nearly fireproof as possible.

The object of installing this house is to remove from the main building all oil-soaked waste and oil-soaked chips, both for the purpose of reclaiming the oil and

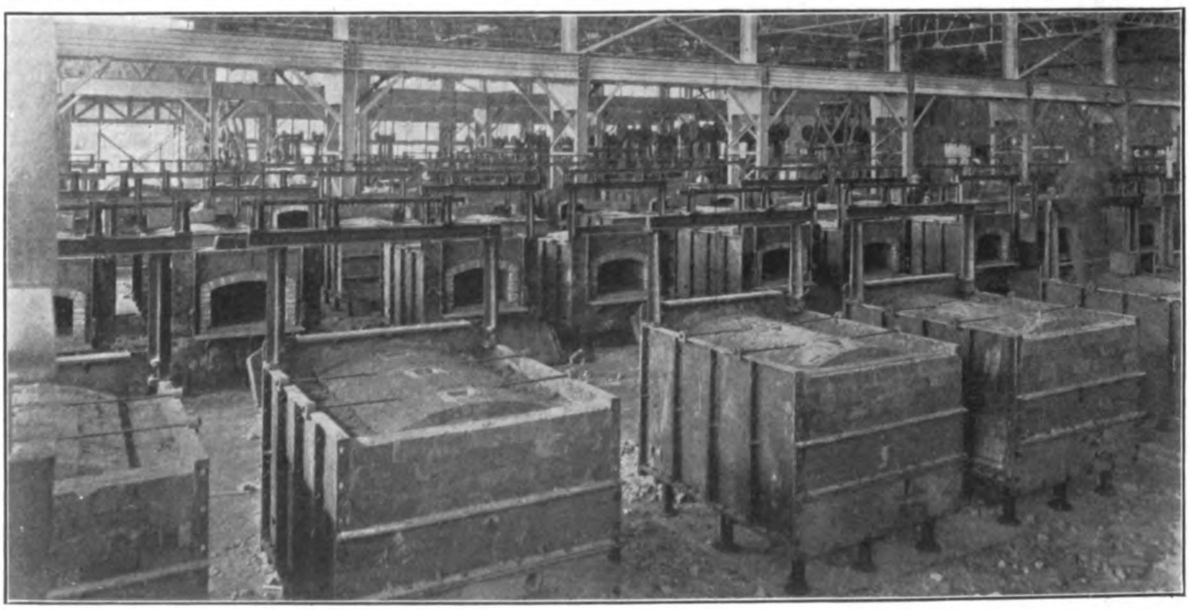

FIG. 7. THE DROP-FORGE PLANT; FURNACES IN THE FOREGROUND AND DROP HAMMERS BACK OF COLUMNS

the waste and also for reducing the fire hazard of the shop itself. The waste is washed, dried and issued again for use. The chips are run through an oil-separating machine and are then dumped directly into the cars in which they are to be shipped away.

The present equipment, as can be seen in Fig. 8, is five steam-turbine waste-washing machines on one side of the building, with foundations and pipe connections for a sixth machine, should this become necessary. On the other side of the building are six oil-separating machines, driven by quarter-turned belts from line shafting and suitable countershafts, the motive power being a 25-hp. 440-volt 3-phase 60-cycle motor, which runs at 950 r.p.m. under full load. The reclaimed oil is piped to the sediment-extracting oil tank and goes from there to the steam-turbine oil filters, shown in the room at the right. Then it goes to a suitable storage tank, which is located underground.

A better idea of the appearance and exact location of both the waste-washing machine and the oil separators can be had from the sectional view, Fig. 9, which also shows the sediment tank, the live-steam hot-water heater and the centrifugal oil filters, as well as the construction of the building itself. This shows the upper and lower floor and the gallery, all of concrete.

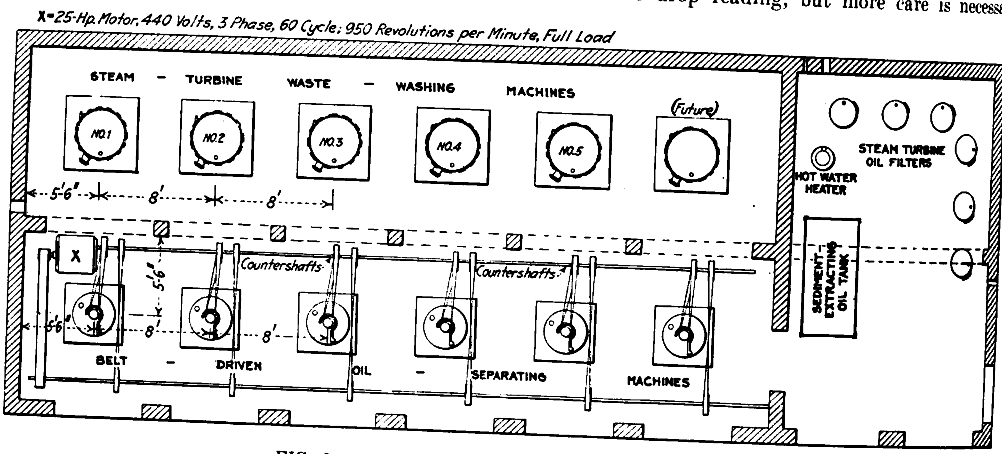

FIG. 8. PLAN VIEW OF OIL-RECLAIMING PLANT

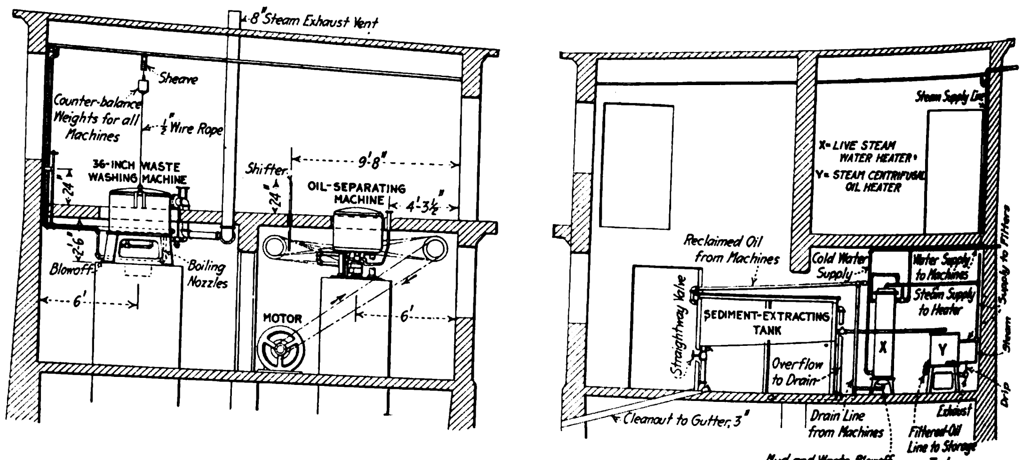

FIG. 9. CROSS-SECTIONAL ELEVATIONS, SHOWING PRODUCERS

Water Flow Through Pipe Orifices

In a paper presented at the spring meeting of the American Society of Mechanical Engineers Horace Judd derived the following conclusions: (1) A thin plate orifice inserted in a pipe is as reliable for flow measurement as the thin plate, or frictionless orifice, as used ordinarily. (2) The shape of the pressure drop curves indicates a maximum point at about ½ pipe diameter from the diaphragm, which would seem to indicate a zone of maximum velocity of flow. (3) The eccentric and segmental diaphragms are advantageous in that they increase the drop reading, but more care is necessary in making the pressure connections, especially on the upstream side of the diaphragm. (4) The best point for the pressure connection is not less than ½ pipe diameter from the diaphragm on the downstream side, and not less than 1 pipe diameter from the diaphragm on the upstream side of the pipe. (5) The 80 per cent. diameter size of diaphragm should not be exceeded to secure uniform flow conditions and to insure steady pressure drop readings. (6) The average coefficient of discharge for a 5-in. pipe diaphragm agrees very closely with the average coefficient of discharge for the 5-in. pipe cap orifice.

Empirical Formulas for the Proportions of Lathes

By A. Lewis Jenkins*

SYNOPSIS—The results of a study of the proportions of 393 American-built lathes, including practically every standard machine made in the country. The formulas cover 40 features of design. They are unquestionably the result of the most detailed study ever made of American lathes.

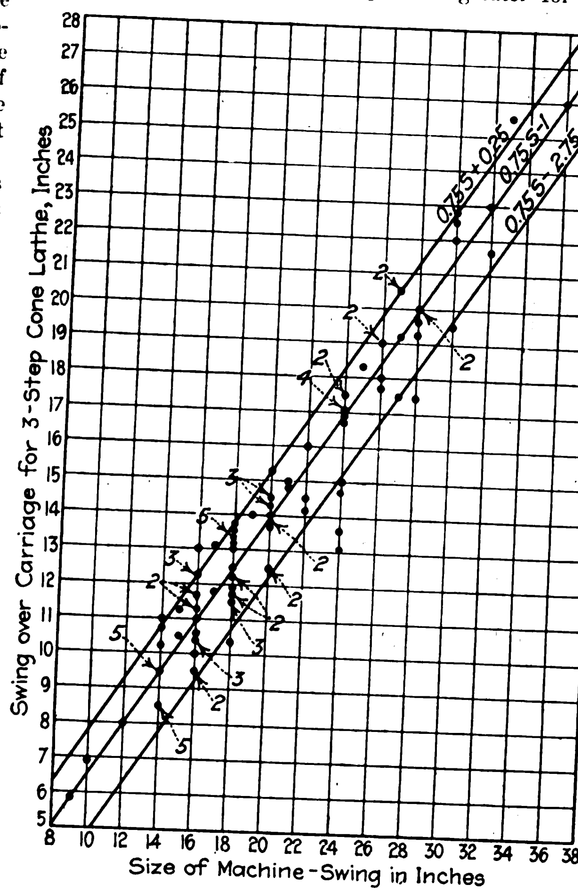
The paper presented by Mr. Alford before the National Machine Tool Builders' Association, on the "Standardization of Machine Tools," and published in Vol. 35, page 725, of the *American Machinist* created an incentive among those interested in machine tools to study the proportions of various machines from the standpoint of the principles he outlined. The results of such a study of American-built lathes is herewith presented, showing the average and limiting values used for the most important proportions.

The data used in this work consist of the specifications given for 393 lathes, and this number practically includes every standard lathe built in this country. The data were tabulated on tracing cloth, from which blueprints were made. These blueprints were gummed, then cut horizontally into strips, giving the data for each lathe on a single strip. The strips were sorted, and the data for the three-step cone, four-step cone, five-step cone and all-geared head machines were collected and arranged in the order of their sizes and mounted on large sheets of paper. This resulted in having all the data for each size and type conveniently collected for comparing and averaging. Each proportion for each type was then plotted against the size of the machine, requiring about 170 sheets of cross-section paper and the plotting of something like 14,000 points. With the exception of only one make the data used in this analysis are more complete than those given in catalogs.

In order to condense the information given by the 170 graphs, empirical formulas were derived for curves or lines through the maximum, average and minimum values. These formulas are given in Table 1. Here S denotes the nominal size of the machine, which is approximately equal to the largest diameter that will swing over the bed. No distinction was made between the light, medium, heavy and toolroom lathes. Many of the data are equally applicable to all and some merely moved from one size to the next, such as results from putting a 16-in. headstock on an 18-in. bed. These variations are accounted for in Table 1 by the maximum and minimum values.

Fig. 1 shows the data for the "swing over carriage" for the three-step cone lathe, and the lines give the maximum, average and minimum values. Great care and my best judgment were exercised in drawing these curves. The maximum and mean values were not drawn through the most extreme point when there were a few extending considerably beyond the range; but enough points, from two to ten, depending upon their position, were considered as being due to error or accident. The maximum and minimum values obtained in this way are not freaks or absurdities and have sufficient practical applications to justify their use. The fields of all graphs, with the exception of those for the highest and lowest feeds and a few others, show a remarkable consistency. Perhaps the most varied or apparently inconsistent are the graphs for the countershaft speeds. In addition to the information given in Table 1 the following conclusions and comments are worthy of mention:

Swing Over Shear—The swing over the shear is practically the same for all cone types and greater for the



PLOTTED DATA FOR SWING OVER CARRIAGE

geared. There is apparently no reason why the swing over the shears should not be standard and equal to $S + 1$, which gives ½-in. clearance between the large faceplate having a diameter equal to the nominal size of the machine and the V's on the bed. The maximum values for the three-step cone and geared types are about a size larger than the average for those types.

Swing Over Carriage—The minimum values for the swing over the carriage show a greater variation from the average than is shown for the swing over the shear. This is probably due to the increased size of the carriage on some of the heavy models.

*Associate Professor of Mechanical Engineering, University of Cincinnati.

* S = nominal size of lathe, which is equal to about twice the height of centers; all dimensions are expressed in inches, weights in pounds.

Length of Bed Minus the Distance Between Centers—This shows the length of bed occupied by the headstocks and tailstocks. This value taken from the length of bed gives the maximum distance between centers. The minimum values for this proportion are apparently small. This is due to the fact that the actual lengths of some beds are greater than specified; for example, the actual length of an 8-ft. bed may be 8 ft. 6 in. in some instances, although it is not generally so made.

Taper of Centers—With very few exceptions the Morse tapers are used exclusively. The relation of the size of the taper to the size of machine may be expressed as follows: No. 2 is used on 10-in. to 12-in. lathes; No. 3 on 12-in. to 16-in.; No. 4 on 14-in. to 24-in.; No. 5 on 14-in. to 30-in.; No. 6 on 24-in. and greater. In view of these data the range could be satisfactorily covered by the three sizes Nos. 2, 4 and 6, although there are about as many Nos. 3 and 5 used as Nos. 4 and 6.

Bearings—The lengths and diameters of bearings on machines built in this country are greater than the values given by Nicolson and Smith in their book, "Lathe Design," which is based on examples of British design.

Belts—The values for the width of belt do not vary as much as might be expected for the cone-type machines, but there is a considerable variation in the widths used on the geared heads.

TABLE 2. RATIOS FOR GEOMETRIC SERIES OF LATHE SPINDLE SPEEDS*

Number of Steps on Cone	Number of Countershaft Speeds	Number of Back Gears	Number of Spindle Speeds	Constant Multiplier, r	Values of Back-Gear Ratios W_1	W_2	W_3	Values of Cone-Pulley Ratios (Duplicate Cones) U_1	U_2	U_3	U_4	U_5

5	2	1	20	$\left(\frac{L}{A}\right)^{\frac{1}{19}}$	r^{10}	.	.	r^4	r^2	1	$\frac{1}{r^2}$	$\frac{1}{r^4}$

*A = first spindle speed; L = last spindle speed; ratio of first and second countershaft speeds = r.

Pitch of Lead Screws—Considerable variation exists in the pitch of the lead screws. More than half of all the machines are fitted with a four-pitch lead screw. The ranges are as follows:

Sizes of Machines, in Inches	Pitch of Lead Screw, or Threads per Inch
14 to 16	6.0
14 to 36	4.0
18 to 54	2.0
30 to 42	1.5
30 to 36	1.0

Seven machines have a 0.5-pitch screw and seven have a 1.5-pitch screw.

Feeds—Where quick-change gear boxes are employed for cutting threads, they are also used for changing the feed. The values of the feeds are from $\frac{1}{12}$ to ½ the threads, the values of ¼ and ⅕ being the most common. Nicolson and Smith state that four feeds are sufficient, and these should equal $\frac{214}{S}$, $\frac{320}{S}$, $\frac{480}{S}$, and $\frac{720}{S}$ per inch, in a geometric series with constant ratio of 1.5.

It is seen that the average American practice is to use smaller minimum and larger maximum values, thereby increasing the range in both directions. It is also average American practice to provide a lathe with about 50 feed changes when a quick-change gear box is used. Lathes not intended for screw cutting have about eight feed changes when geared and either three or six when belted. The smallest feeds on three-step cone lathes do not seem to bear any relation to the size of the machine and vary from 80 to 450, with an average of about 180 turns per inch when a gear box is used.

Threads—The minimum number of threads per inch or the largest threads that lathes will cut are limited to the values of 0.5, 1, 1.5, 2, 3 and 4. Only a comparatively few cut 3 threads per inch. The values for the smallest threads are represented in Table 1.

Countershaft Speeds—The ratio of countershaft speeds must be equal to r the constant multiplier in the geometric series, in order to produce spindle speeds in a geometric series. In many instances the ratio of the countershaft speeds does not check with the value of r obtained from the maximum and minimum spindle speeds or from the cone-pulley ratios.

The countershaft speeds are quite variable. The values given for the averages meet the requirements of the geometric series, based on the value of r computed from the highest and lowest spindle speeds, with the exception of the four-step cone machines that are larger than 24 in. For the four-step cone double back-geared lathes having two countershaft speeds the average values are as follows: $r = 1.27$; maximum spindle speed $= \frac{7,800}{S}$ r.p.m.; diameter of largest step on cone $= 0.68S$ in.; diameter of smallest step on cone $= 0.298S$ in.; fast countershaft speed $= \frac{3,750}{S}$ r.p.m.; slow countershaft speed $= \frac{2,950}{S}$ r.p.m.

Spindle Speeds—Considerable variation is found to exist in the speeds given by lathes of the same type and size and designed for the same class of work. It is not uncommon to find a variation of as much as 50 per cent. in two lathes of the same size and duty, built by two different concerns of equal reputation. The values of the geometric ratios, ratios of back gears, countershaft speeds and diameters of steps on cones give evidences of the existence of several important considerations that have been taken into account by the designers. The four most important of these are: (1) The maintenance of a constant geometric ratio on all sizes; (2) the slowest spindle speed such as will give a constant cutting speed on a diameter equal to the nominal size of the machine or faceplate diameter; (3) large back-gear ratios; (4) maximum belt velocities.

Constant Geometric Ratio—The value of the geometric ratio may be considered as constant for each type of American-built lathe, such as three-step cone, double back geared, but varies with the type and number of speeds given by a single type, such as an all-geared head. There is considerable variation in this value when based on the highest and the lowest spindle speeds, but this is largely due to the fact that many machines do not give a geometric series of spindle speeds. The relation of the geometric ratio r to the highest and lowest speeds, back-gear ratios and cone-pulley ratios are given in Table 2. This shows that the back-gear and cone-pulley ratios are entirely dependent upon the value of r.

Constant Cutting Speed on Faceplate Diameter—The slowest speed for a given type of lathe may be found by considering a constant cutting speed either on a diameter equal to the nominal swing of the machine or on the largest diameter that will swing between centers and over the carriage. This, together with the constant value of r for each type of lathe, results in a constant ratio R, of the highest and lowest spindle speed for each type.

Nicolson and Smith give the same highest and lowest spindle speeds for all cone-type lathes for the same duty, the highest and lowest speeds on a three-step cone, double back-geared lathe being the same as for a five-step cone, single back-geared lathe. This causes the value of the geometric ratio to vary not only for the type, depending upon the number of speeds, but also for each size of a given type. It also gives different values for the geometric ratio for every possible lathe, whereas the average American practice is to make the ratio constant for each type.

Large Back-Gear Ratio—A large back-gear ratio has been looked upon by some as being a desirable feature. This will of course increase the available spindle torque on the slow spindle speeds by merely decreasing the speeds below those in the geometric series, but does not increase the available power for the first, second, third, etc., speeds, which is dependent entirely upon the belt velocity and efficiency of the machine. The available power for the first three speeds for a three-step cone lathe cannot be altered by changing the back-gear ratio. However, there is more available power at the third speed than at the first in any cone-type machine; and if the back-gear ratio is large enough to lower these speeds considerably, the lathe will have a greater power for a given diameter of work and cutting speed. The large back-gear ratio increases the belt velocity for a given revolution per minute of the spindle, which is desirable in making more power available at the tool.

The average value of the second back-gear ratio for a three-step cone lathe is 10.9, based on the value of a geometric ratio equal to 1.22 computed from the average values of the highest and lowest spindle speeds on the assumption that the speeds are in geometrical progression. This ratio may be increased to 14.6 by making the geometric ratio equal to 1.25 and $R = 44.5$ instead of 29.5; and by properly changing the cone-pulley ratios the speeds will be in a geometric series without the large gap caused by increasing the back-gear ratios without correcting the cones. Hence, it is possible to make the back-gear ratios much greater than the average and maintain a geometric series of speeds; but the ratio R may become undesirably great, and the small step on the cone becomes undesirably small.

High Belt Velocity—The available power is proportional to the belt velocity and varies with the diameters of the steps on the countershaft cone or with the speeds of the cone on the machine. On the five-step cone machine with diameters of steps ranging from 6 in. to 18 in. the available power and belt velocity at the highest speed of the driven cone are three times as great as for the slowest speed. When the cone is on the spindle, high spindle speeds result from high belt velocities. The lower spindle speeds may be reduced by increasing the back-gear ratio, but this gives a gap in the spindle speeds. Hence, higher powers and belt velocities are best obtained by having the cone off the spindle or by using an all-geared head with a single pulley drive.

Table 3 shows the values of the back-gear ratios, cone-pulley ratios and cone-pulley diameters that give speeds in geometrical progression for practically all cone-type mechanisms used in this country in the design of lathes. The values given for the geometric ratio, or constant multiplier r, are those found to be the average for the various types and those suggested by Carl G. Barth.

Mr. Barth suggested (*American Machinist*, Vol. 36, page 52) that one of the two values $\sqrt[4]{2} = 1.189$ and $\sqrt{2} = 1.414$ might be used in the design of any lathe. Averaging the values of r given for the 8-, 9- and 10-speed machines gives 1.58, and for the 16-, 18- and 20-speed machines gives 1.25. These values, approximately equal to $\sqrt[3]{4}$ and $\sqrt[6]{4} = \sqrt[3]{2}$, come nearer to the values actually used on lathes than those suggested by Mr. Barth.

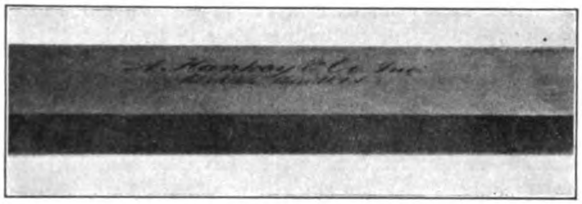
Etching Names on Steel

The accompanying illustration shows a very good example of deep etching by A. Hankey & Co., Rochdale, Mass. This process is used for etching names on both high-speed and carbon-steel hardened blades and straightedges and requires but a few moments.

It is necessary to have a raised impression of the name on a steel plate. This is used as a master impression and resembles the raised characters on a rubber stamp, except that it is direct, not reversed, and is raised only a slight amount.

Beeswax and lampblack are boiled in turpentine to the consistency of soft putty and well worked by the fingers, so that all lumps and hard spots are removed. This mixture is warmed and then rubbed over the master impression, filling the spaces between the letters. Transfer paper, known as the G. B. etching tissue, made by C. H. Dexter & Sons, Windsor Locks, Conn., is applied over the wax on the master impression. It is rubbed down into close contact with the surface of the letters. The tissue paper is then stripped from the master impression and brings with it a coating of the wax and a reversed impression of the lettering, similar to a stencil in wax, backed by tissue paper.

This transfer is applied face down to the steel that is to be etched, which must be ground very smooth and



NAME ETCHED BY ACID PROCESS

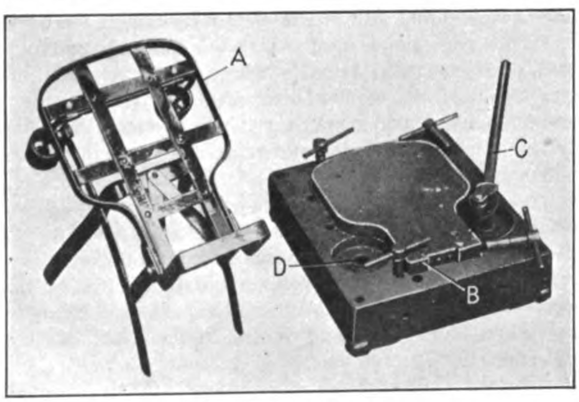
polished with emery cloth. It is rubbed into contact with the steel by a rubber roll. The paper is then removed by moistening it with water and rubbing it off with a finger. Sometimes it is necessary to retouch the waxed steel, in order to fill small pin holes and the like, which is also done with the finger.

The etching acid consists of a mixture of two-thirds muriatic and one-third nitric, being diluted with water in the proportion of 1 to 2. It is applied to the work by means of a glass tube, only sufficient being used to cover the letters. The acid is allowed to remain upon the steel, a length of time depending on the depth of etching desired, after which it is washed off and its action neutralized by a few drops of potash solution consisting of a small amount of potash dissolved in water. The results of this process are superior to those secured by a number of so-called secret processes that are kept religiously guarded.

A Bending Fixture

The frames of the tandem seats used on Henderson motorcycles are made of heavy band iron. The outer frame is bent to shape in the fixture shown. One of the completed seats, without the cushion, is shown at the left and the part that is bent in the fixture is indicated at A.

The method of using the bending fixture is first to remove all pins and the radius lever. The end of the piece of iron is then placed at B and a pin inserted in



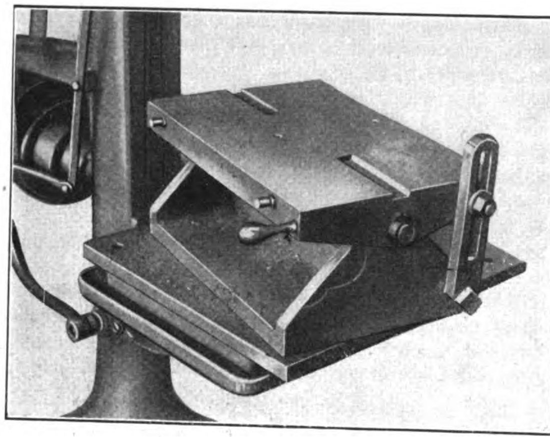
A BENDING FIXTURE

the hole just in front of it. The corner bend is then made, bending the iron in far enough so that the radius lever *C* can be placed in the hole *D*. By turning this lever the roller end forces the iron into the form. The iron is now bent around the form, using pins to hold it wherever necessary until the position is reached where the radius lever has to be used again, when the end of the iron is brought around to meet the other end. The main parts of the form and base are made of cast iron, but steel pieces are inserted at the corners and a steel bushing is used for the radius lever to turn in.

Handy Tilting Table

The illustration shows a handy tilting table used in the shop of the Millholland Machine Co., Indianapolis. Ind. For drilling holes at an angle it is unusually convenient; and constructed in the way it is, it is rigid.

The work table is 12 in. wide, 18 in. long and 1⅝ in. thick. The trunnion is made of a piece of 1-in. bar. The



A HANDY FITTING TABLE

table is about 8 in. high. The pins shown in front and the grooves in the table are for locating some special work, but any ordinary work may be easily clamped to the table when desired.

Shell Inspection Incident

Some of the manufacturers of munitions have had interesting experiences with the inspectors from foreign governments. Many of these incidents are amusing, others vexing and still others even worse. For the most part, however, the inspectors are fine fellows, generally well posted and amenable to reason so far as their instructions permit. Few of them were accustomed to our methods, and many knew only the practice of the older arsenals, which is not always modern, to put it mildly. One experience with a shell inspector is of interest.

The first hundred shells had been made to see what could be done and to have them looked over before going ahead with the job. The inspector found some little discrepancy—the outside diameter was a trifle large by his gage—so with all his authority, plus a good-sized hammer, he proceeded to strike and dent each shell that did not pass muster.

Now the maker was a fine mechanic, with as much ingenuity as any man I have ever known; and it hurt him to see good work bruised beyond repair without knowing the reason why, for the inspector had maintained a silence that would put the sphinx to shame. When he swatted the tenth shell, the maker decided to call a halt. So he talked to the inspector after this manner:

"Let's have a better understanding about this, my friend, but don't think I want to put over on you anything that isn't right. Just remember those are *my* shells now. I bought the steel and paid for all the work. If they aren't right, I don't want you to take them. But I do want to know what's wrong with them.

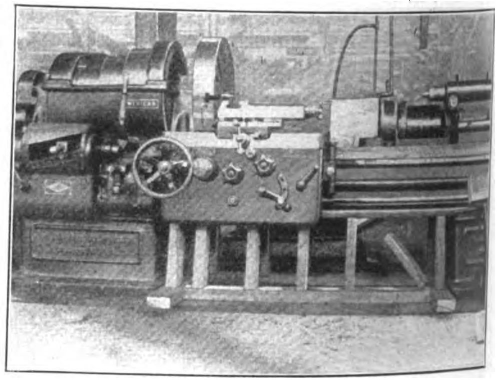
"These 90 shells are *mine;* those you've spoiled so I can't fix 'em are *yours.* Any more you spoil are yours—and must be paid for. If I spoil them, I pay for them, of course.

"Let's just understand this game right from the start. Tell me what's wrong, and I'll make it right or make new shells. But don't go destroying my shells with your hammer. If you do, you pay for 'em or we don't make another shell."

The inspector saw the point, for he was a decent sort of chap. He'd been trained wrong, that's all. They had no further trouble and became quite chummy before the contract was finished.

Bracing Lathe Beds To Prevent Distortion in Transit

The bracing shown has been made to avoid disappointment and delay to customers, owing to lathe beds being sprung out of shape by strains set up in shipping. This



BRACING LATHE BED AGAINST DISTORTION

photograph was taken just as the lathe-bed braces were being knocked out of the way. The braces are short struts set in between the skids and the lathe bed. They are fitted both at the front and the back of the bed, as shown.

Low-Grade Fuels in Producers—It is pointed out in a paper recently published by the Bureau of Mines that within the past five or six years marked progress has been made in Europe in the utilization of various kinds of refuse material not ordinarily given much consideration. The manufacturers of gas producers report the successful use of a large variety of fuels, including wood shavings, wood blocks, sawdust, excelsior, coffee husks, rice husks, cocoanut shells, straw and spent tan bark. The figures on fuel consumption reported by the manufacturers are about as follows: With reasonably dry wood (say mixed oak, ash and elm) the consumption has been as low as 2 lb. per b.hp.-hr.; with sawdust the consumption averages 3½ lb. per b.hp.-hr.; and with spent tan bark containing 50 per cent. moisture it is about 4½ lb.

Machining Automobile Parts

EDITORIAL CORRESPONDENCE

SYNOPSIS—The machines described have been specially designed to perform certain operations and have been provided with means for both hand and machine feed. The tool for machining the valve-guide holes has two spindle speeds. This is advisable, as the holes are small in comparison with the larger surfaces, which are beveled and faced in the second operation.

The Dile Motor Car Co., Reading, Penn., has designed and built several special machines for manufacturing automobile-motor parts. In Fig. 1 is shown the machine for boring and reaming the cylinders.

The casting is located by two bars *A*, against which the bosses on the cylinder rest. The holes are first bored with heads *B*, which are fitted with two inserted cutters. The heads are then removed, the reamers inserted, as shown, and the holes reamed to size. The various tools are guided through bushings in the flange *C* of the fixture. A view of the driving side of the machine is given in Fig. 2. The table carrying the cylinder is fed up against the revolving cutters by a worm and wormwheel, and the screw shown at the rear is operated by the pulley *A*.

When it is desired to lower the casting for replacing with another cylinder, the clutch *B* is thrown out of contact with the foot-operated lever *C*. The handwheel *D* is revolved, operating the screw that lowers the table and casting. The average time required to bore and ream a cylinder is 10 min.

The machine for drilling, reaming and facing the valve-guide holes and valve faces is shown in Fig. 3. The casting is located by two plugs that fit into reamed bolt holes in the flange, while the cylinder is held in position by the two clamps *A*. The valve-guide holes are drilled with the tools shown, which are placed the correct distance apart. The drills are driven through a worm and wormwheels by the pulley *B*.

The table carrying the cylinder is fed by a screw operating a nut that is revolved by the wormwheel *C* and gears *D*. It will be observed that the machine is provided with two rates of table feed. The upper gear may also be slid on a spline attached to the shaft into a neutral position between the gears.

The table may be fed by hand by the handwheel *E*. After the holes have been drilled, combination facing, beveling and reaming tools are placed on the spindles. The holes are reamed, faced and beveled with the machine operated in a similar manner to that described.

Two speeds of the spindles are obtained by gears placed in mesh by clutches controlled by the handle *F*. It moves the shaft, which in turn slides the clutches into the required positions. The time taken to machine the valve guide is 15 min.

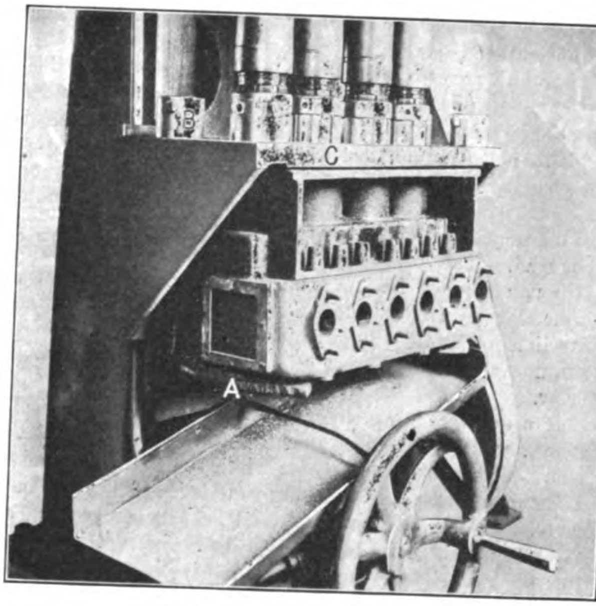


FIG. 1. MACHINING CYLINDERS

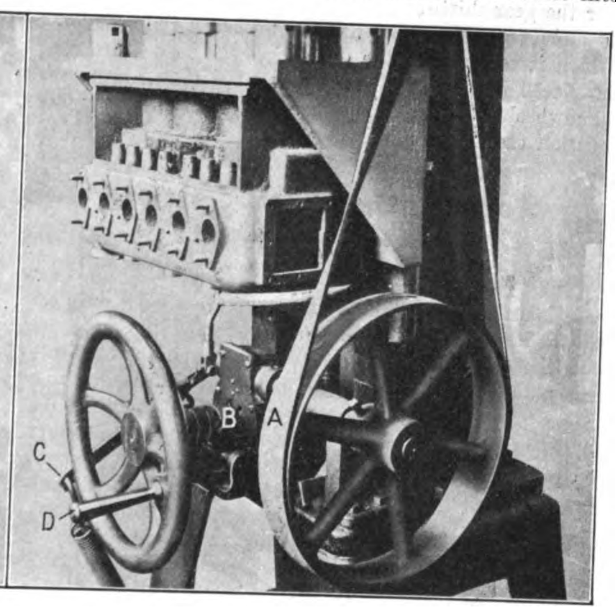

FIG. 2. DRIVE SIDE OF MACHINE

The machine for boring and facing the differential housing is illustrated in Fig. 4. The casting has the axle holes drilled in a previous operation, and the arbors *A* are inserted in the machined holes. The screws in the clamp *B* are tightened against the casting to hold it securely in position. The boring bar and facing tool are revolved by the pulley *C*.

A belt placed on the shaft end *D* drives the pulley *E*, which feeds up the table and casting by a worm and wormwheel that operates the screw shown at the rear. This screw fits into a nut attached to the work-holding table. When it is desired to feed the table by hand, the power of the pulley *E* is thrown out of mesh by a clutch, so that the table may be operated by the pulley *F*. The time necessary for this operation is 8 min.

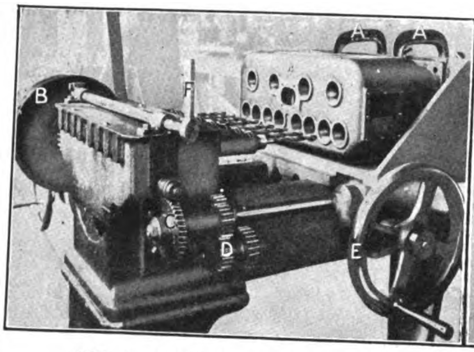

FIG. 3. DRILLING, REAMING AND FACING THE VALVE GUIDE HOLES

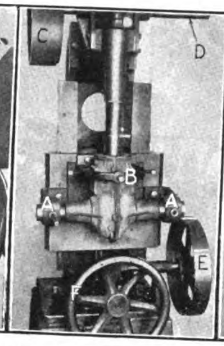

FIG. 4. BORING THE DIFFERENTIAL HOUSING

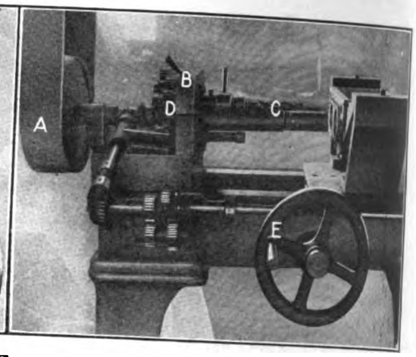

FIG. 5. METHOD OF MACHINING TRANSMISSION CASES

The machine for boring the transmission cases is shown in Fig. 5. The casting is located on dowels that fit into previously machined holes. The various tools are revolved through gearing by the pulley *A*.

Feed to the table is obtained by a screw through gears and the worm and wormwheel shown. The two positions for the gear-shifting lever holes are obtained by the pin *B* and two positions of the sleeve carrying the drill *C*, which is revolved on the gears *D*. The feed gears may be placed in a neutral position and the table fed by the handwheel *F*. The average time for machining a transmission case is 30 min.

Secrecy in Rate Setting Not Desirable

By John Bailey

It is an axiom of shop management that rates once set should never be cut. How does this affect the employee and the employer? In considering the individual rate this plan is very satisfactory to the employee; but if a rate is set on a somewhat similar piece, he is still at the mercy of a dishonest rate setter. It is also satisfactory to the employer, unless the rate is set too high through error or other cause. Then it is an injustice to the employer not to be able to correct the mistake.

When a new method of doing a piecework job is adopted, there is always a chance for ill-feeling. It is certainly just that the rate should be changed if a faster method of doing the work is discovered by the management. This fact, I believe, will be admitted by any fair-minded mechanic. In practice, however, it often leads to trouble, as there is nothing to prevent a dishonest rate setter from cutting a rate 25 per cent. because of an improvement that may save 5 per cent. of the time. In other words, there is nothing to prevent the management from adopting a minor change of method in order to have an excuse to cut a rate.

I think everybody will admit that standard piece rates are not as satisfactory as they might be. In their place I would suggest a standard method of rate setting for each plant, understood by the workmen and never to be changed. The four items entering into the setting of rates are:

1. The time consumed by the machine on all the operations—that is, the time taken to make a cut on a lathe from the moment the feed is thrown in until it is thrown out again.

2. The time consumed by the operator on all operations—that is, the time taken to throw out a feed, swing the turret, throw in the next and handle the piece.

3. The allowance made for resting or other purposes.

4. The amount the operator will earn, provided he does his work in the set time. This sum should be at least 25 per cent. more than for daywork. The amount will of course be larger if he uses his rest periods or becomes more proficient and betters the time allowed under 2.

I would suggest that the operator be taught the method of rate setting and that time allowances under 3 and 4 should be guaranteed standard and not subject to change.

This policy would then leave us only two items subject to change. If a new tool steel is purchased that will stand a higher speed or feed, the time allowance under 1 would be shortened, but the other three items would remain unchanged. The rate would be lowered; but the man, although doing a few more pieces, would still make the same wages. It would entail a little additional physical exertion to handle a larger number of pieces, but a man running a machine is very seldom bothered by the actual labor.

If a quicker-acting chuck that saves time is designed, item 2 would be changed and the other three be left intact. This result is just, for while the man will make a few more pieces, his chucking time is shortened on each piece. He does no more work and gets the same pay.

When a change is made at the suggestion of the operator, the rate should be set so as to give him the benefit of at least 50 per cent. of the time saved.

I have set quite a few rates at one time and another. I always show the operator just what time he takes on each operation and how I figure his rate. In fact, I do it with the operator looking right over my shoulder. I have never had any dissatisfaction over a rate and have always credited this success to being open with the men and not making a mystery of time setting.

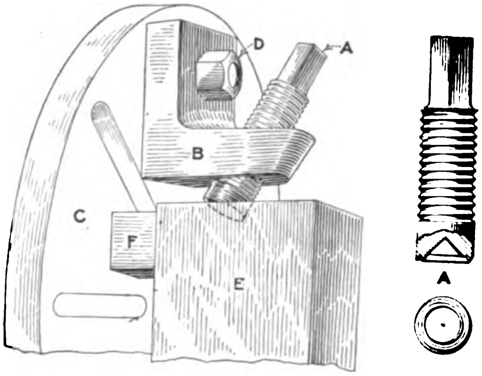
I have never tried on a large scale the system here outlined, but I believe it will work just as well and that secrecy does more than anything else to cause dissatisfaction with the setting of rates under scientific management.

To Remove Grease from Parts of Machinery the following method has been substituted in Germany for the use of gasoline and other light oils because of the scarcity of the latter: Boil the parts in soda-lye, then brush while the lye is still hot. Caustic soda is recommended as better than ordinary soda, since it causes the fat or grease to dissolve more quickly.

Letters from Practical Men

A Faceplate Dog

The illustration shows a dog for holding on the faceplate work that is to be machined. It consists of a steel screw *A* housed in the angle block *B*, which is bolted to the faceplate *C* by the nut and bolt *D*. The piece to



A FACEPLATE DOG

be machined is shown at *E*. A parallel block *F* is between *C* and *E*. The point of the screw *A* is made in the form of a spiral thread.

The rear of *A* is made square to fit the socket wrench. The function of the screw is to hold the piece *E* securely centrally and to draw it down solidly on the block *F*, thus insuring a parallel job.

G. L. JOHNSON.

McKeesport, Penn.

Sizes of Tap Drills for Varying Conditions of Work

The table of tap-drill sizes for machine screws shown herewith was derived from a series of exhaustive tests made to determine the size of drill best suited for tapping different materials of various thicknesses, or depths of hole, under ordinary manufacturing conditions. This study included the consideration of the minimum amount of tap breakage and at the same time the production of a thread of sufficient depth to serve the purpose for which it is intended.

The sizes given will not allow enough stock for a full thread, but take into consideration the strength of the tap and the amount of metal it can remove without breaking, as well as the strength of the screw itself; that is, a fine-pitch tap of a given size will be able to cut a relatively greater percentage of the full thread than a coarse-pitch tap of the same diameter.

Let us take for illustration a No. 8-32 tapped hole in a brass casting, where the depth of hole equals twice the diameter of tap, or more, this being considered as thick metal.

Referring to the table, we find that a No. 27 drill is recommended, which will give us approximately 50 per cent. of the total depth of thread. This is sufficient when we consider the root diameter, or strength of the screw. Under these conditions the screw will break before the threads can strip.

If we wish to tap this same casting for a No. 8 screw having 40 threads per inch, instead of 32, we find from the table that this also requires a No. 27 drill, which gives us approximately two-thirds of a full thread instead of 50 per cent., as will the other screw. But we have a greater root diameter in the latter than in the former

TAP DRILLS FOR VARYING DEPTHS OF BRASS AND STEEL

case and therefore have greater strength in the tap. We have of course a stronger screw, but to compensate for this we have a greater percentage of thread to resist stripping.

Numerous tables of tap drills are available, but they all differ more or less; and in most cases the sizes recommended are too small for general manufacturing purposes, thereby causing a large amount of tap breakage, which must be added to the manufacturing cost. Anyone having large quantities of holes to tap will find this table very

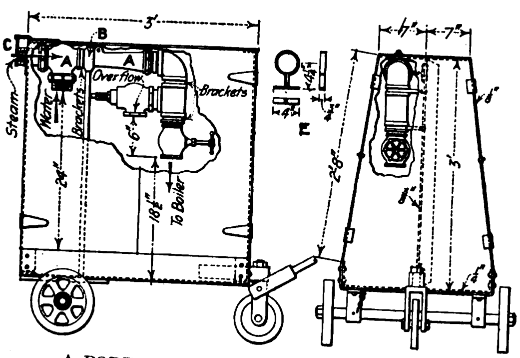
valuable as a reference. It must be remembered that, while some of these drills seem to leave very little thread, even a sharp tap forces up some metal and that a dull tap will greatly increase the amount of thread in the hole.

Indianapolis, Ind. O. R. KLEPPER.

Boiler-Washing Outfit

The boiler wash-wagon shown herewith is handy, because it can be easily hauled around the shop or engine house for one locomotive or another. The bottom end plates and one top of the box are of ¼-in. boiler iron. The center or partition plate is ⅜ in., flanged and riveted to the end plates, which are flanged at top and bottom and, of course, riveted.

A nice thing about this wagon is that there are doors on each side, hinged at the end plates and meeting in the center. They are provided with hasp, staple and lock,



A PORTABLE BOILER-WASHING OUTFIT

so no one can "borrow" the hose. One side is entirely for hose, and both sides are closed and locked when not in use.

The ejector is shown at *A*. The other fittings are ordinary, an overflow being provided as indicated. *B* is a kickoff with a pipe leading toward the floor. Hose is attached to the overflow and leads to the pit on the sewer.

A washer or plate *C* is placed over the steam end, to prevent dirt from getting into the ejector tubes. The ejector and fittings are held to the center sheet by means of four small brackets *E*. All connections can be easily made, the doors, of course, being open when in use.

Renovo, Penn. JOSEPH K. LONG.

Clearing Chips from Deep Holes

A case where a little ingenuity saved a shop a good many dollars in both drills and time was recently brought to my attention. The work consisted of a series of manganese-steel forgings, in which a number of holes were to be drilled for bolts and for oil leads. These holes were of small diameter and ranged from 4 to 7 in. in depth, depending upon the thickness of the material at the point drilled. For the first 2 or 3 in. the drills would work well and clear satisfactorily; but as the holes deepened, the chips would jam against the walls of the hole, the bit would seize and in many cases break off before the operator was aware that trouble was brewing. Compressed air was tried for blowing out the chips, but was found to lose its effectiveness at a point but little below that where the fluting of the drill served to remove the chips.

The trouble became so bad that the drill-shop foreman figured one-half of the time spent in drilling the pieces was wasted in trying to clear the holes. The number of drills broken mounted so high that profits began to disappear before being really earned. Finally, as a last resort, the inner winding was taken from an induction coil belonging to an old motor car stored in the shop's pattern loft. This coil was fastened to one end of a steel rod having a diameter slightly less than the smallest of the holes to be drilled and the coil connected to it through a push-button switch and heavy insulated wires, then to a set of six dry cells on the floor beneath the drill press. The work was carried out experimentally by drilling 1 in. and then inserting the magnet into the hole and switching the current on. The magnet was withdrawn, bringing most of the chips with it, and the circuit was broken by releasing the switch. The chips dropped as the bar became demagnetized. The magnet was then used as a probe a second time, to remove the remainder of the chips.

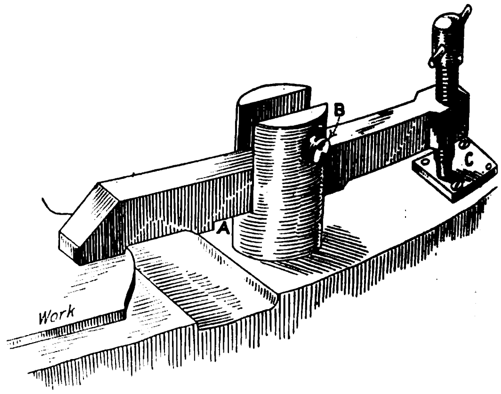
Contrary to the predictions of some of the shopmen, the chips did not show any great attachment for the sides of the hole, but instead adhered closely to the magnet bar. After a few trials it was found that the magnet, on account of its being of steel, retained a part of its magnetism and therefore refused to part with the chips readily. A soft cast-iron rod was machined to the proper size and used as a magnet pole with satisfactory results. The experimental magnet was so successful and required so little time for its operation that one was provided for each drill press. The job was finally turned out at a profit instead of the large loss feared when the trouble made its appearance.

Pittsburgh, Penn. CHARLES C. LYNDE.

A Notched Clamp

The illustration shows a simple clamp that I have not yet noticed in print. It is notched at *A* instead of having the usual elongated hole through it. The hinge pin *B* is above the clamp.

When the screw is released, the clamp drops away from the pin *B* and is easily slid back. The screw point slides



A NOTCHED CLAMP

on the hardened block *C*. The notch *A* must be long enough to allow the clamp to slide away from the work. Clamps of this type have been found strong.

Milford, Conn. CHARLES W. OVIATT.

Spherical-Seat Boring Bar

This boring bar has been designed for boring the spherical seat of the grinding spindle head shown in Fig. 1. After a straight hole has been bored in the piece, the bar is inserted with the cutters in the farthest position to the right.

The bar *A* fits into the spindle of a horizontal boring machine. It is slotted, as shown, to provide two chambers for the cutters *B* and a guide for the link *D*. The two cutters are hinged on pins *C* and are stepped to take the cut in two chips. The star wheel *F* acts as a nut on the screw *E*, which pulls on the link *D*. This star wheel is so shaped that it will allow the screw to deviate from the central line of the bar with the motion of the cutters. The piece *G* supports the screw and is provided with a curved seat for the nut *F*. A spring *G*, bearing against a curved washer *K*, keeps the nut in place. P. P. FENAUX.

Newtownville, Mass.

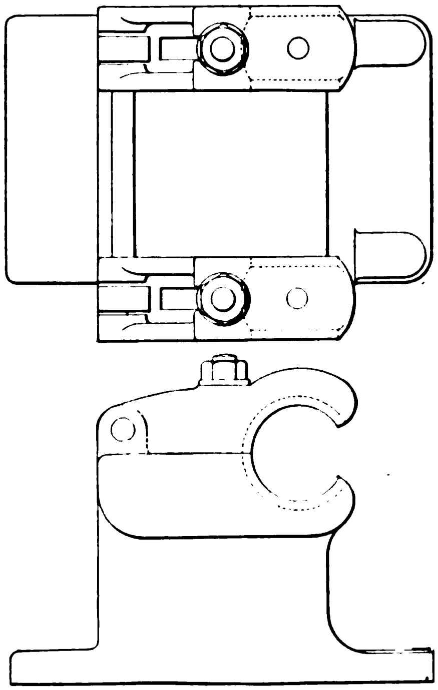


FIG. 1. SPHERICAL BEARING SEATS IN GRINDER HEAD

Is the Evening Trade School Worth While?

The ordinary citizens who give the matter of evening trade schools a thought must view them as places of inspiration and advancement for the ambitious young mechanic. To them it must seem that a person who has the energy and ambition to rush home at the close of a hard day's work, gulp his evening meal and hurry to the school must have all the qualifications that go toward success and must therefore be deserving of a goodly portion of the taxpayers' money in the support of such institutions. And it is for the ambitious that the evening trade school is maintained.

The principles underlying the foundation and maintenance of the school coincide with the ideals of the citizen. Theoretically, it gives the pupils a supplementary training in the evening that will aid them in taking the next step forward in their daily work.

School supporters in general realize that men in factories are not hired with any idea of helping them to advance by trade training, but for their immediate power of productiveness. To assist worthy mechanics to a better development in a knowledge of their trade, the taxpayer approves a considerable appropriation. The idea of the taxpayer is not to get any financial return to the city for its investment, but so to better the training of workmen that their added wage and intelligence will count toward civic betterment. Is the taxpayer getting his money's worth?

Being an instructor in evening trade-school work, my knowledge of the situation as I see it from the inside may be of interest. Experience shows that, while many register, a very large number drop out as the term advances. Those who drop out with but a rudimentary knowledge

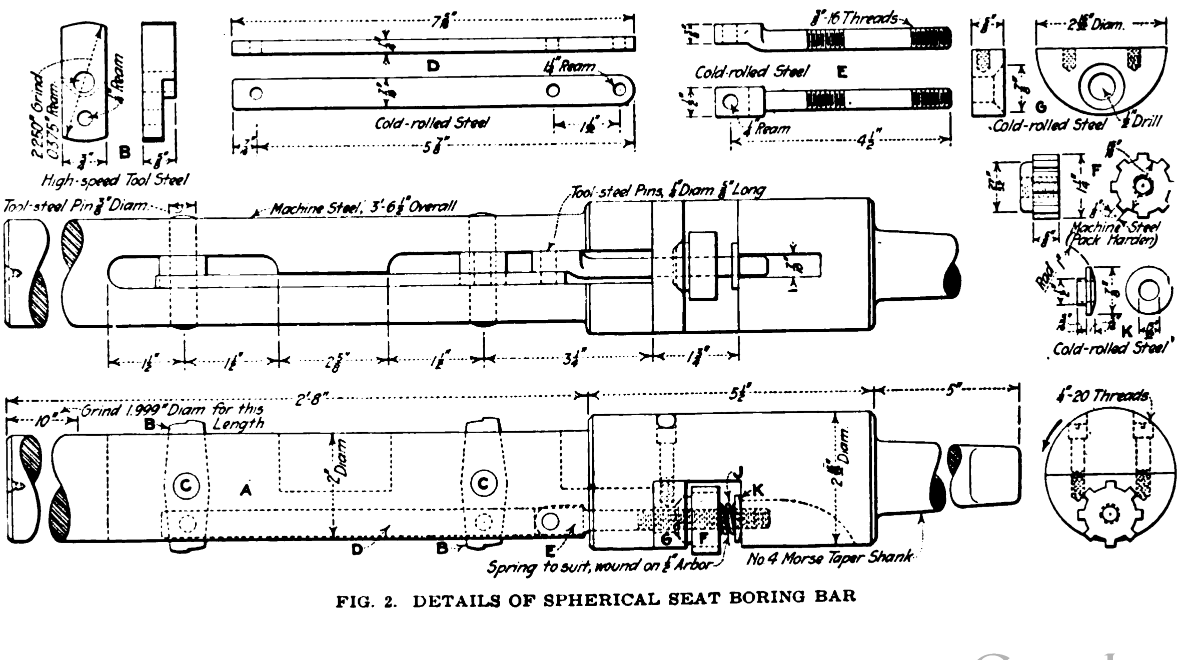

FIG. 2. DETAILS OF SPHERICAL SEAT BORING BAR

of the operation of a machine are really a menace. The school simply gives them a basis for bluffing. When they leave the school, they too often pose as competent operators and start on their career of spoiling work and getting fired until they really become skilled through the experience gained in different shops. But the manufacturer pays for this sort of training in the work spoiled, the entire fraternity of machinists loses and the school loses much in reputation.

It is discouraging to the instructor to attempt to take the interest he should in a floating group. The general belief in the type of men who take advantage of evening trade-school instruction will bear revision. It is by no means a seleced group of men having promotional capacity. Some (but these are the decided minority) are naturally bright and are a delight to the instructor. The prospect of training them toward a specific goal is always pleasing. The majority, however, who require more repetitive work than the limited number of evenings justifies, show little inherent ability to grasp or absorb instructions, to say nothing of ever being able to advance on their own initiative. Their record shows a considerable shifting about from place to place and from job to job, and no amount of training will get them much more than their initial wage. There are of course some exceptions who have ability enough in a way, but they direct it toward using the evening school as one of the stages in the evolution of "picking up" a trade.

Some pupils attending evening schools are, to an increasing degree, too recently of such different foreign environment that they cannot profit by the instruction sufficiently to warrant their seeking work in the trades. Their entrance into a shop under the guise of a skilled workman would tend to lower conditions in the factory. To me the word "machinist" should express the qualifications and experience which the name implies, and I always feel averse to lowering in any way the dignity of the calling. Perhaps this is what has led me to write this article.

On the other hand, when the taxpayers' money is considered, it may be reasonable to suppose that the public is willing to spend money on evening trade-school work for the sake of the minority whom it helps toward advancement. The public always has in mind an ideal. A single Edison would justify an enormous expenditure. The promotion of one evening trade-school graduate to a shop superintendency would sink into oblivion all other failures.

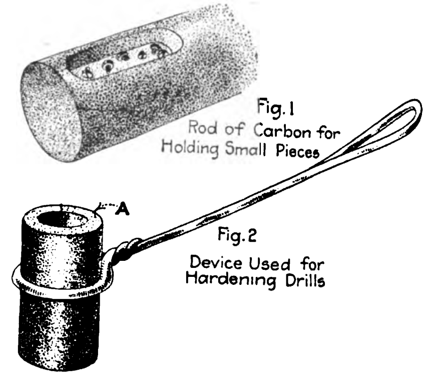
And of course there is always in mind the small proportion of men being trained in evening schools as compared to the whole number employed in the industry throughout the country. In Massachusetts the 7,000 students under evening trade-school instruction at present is but 1 per cent. of the whole number of employed adults.

Looking the situation over carefully from my point of view, I would make a few suggestions: Let the supplementary trade training be given to the skilled to make them more skilled, not to the unskilled—at present at least; establish a better measure of the ability of the applicant to profit by the instruction; consider a man's attitude toward his work, as shown by his record; and place more emphasis on the fact that the aim of the school is to open the way to future advancement in the trade along the usual channels and not by any tempting short-cut.

Worcester, Mass. ROBERT J. SPENCE.

Hardening Small Pieces

For hardening small drills or screws, pieces of arc-lamp carbon may be drilled or scooped out, as shown in Fig. 1, and used for holding the pieces while heating. It was necessary to drill several hundred holes 0.0135 in. in diameter for a number of small spring collets. The drills were not hard enough for the purpose, so they were hardened in a cup made by drilling a hole in a piece of



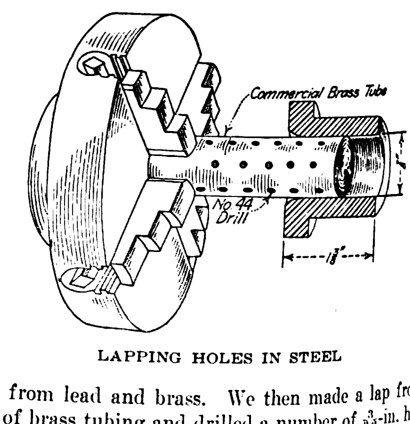
HARDENING SMALL PIECES

carbon and attaching a piece of wire, as in Fig. 2. If these small drills had been hardened in the open flame, an even heat would have been difficult to obtain and the danger of burning would have been great. The drills were heated in the cup A to the desired extent and dumped vertically into a pot of sperm oil. The results were satisfactory.

Newark, N. J. GUSTAVE A. REMACLE.

Lapping Holes in Steel

Some time ago we had a number of pack-hardened steel bushings with a ⅞-in. hole 1⅜ in. long to be lapped out. About 0.0015 in. of metal was to be removed. The holes were from 0.001 to 0.002 in. out of round after trying laps



LAPPING HOLES IN STEEL

made from lead and brass. We then made a lap from a piece of brass tubing and drilled a number of $\frac{3}{32}$-in. holes, staggered as shown, and found we gained about 50 per cent. in time.

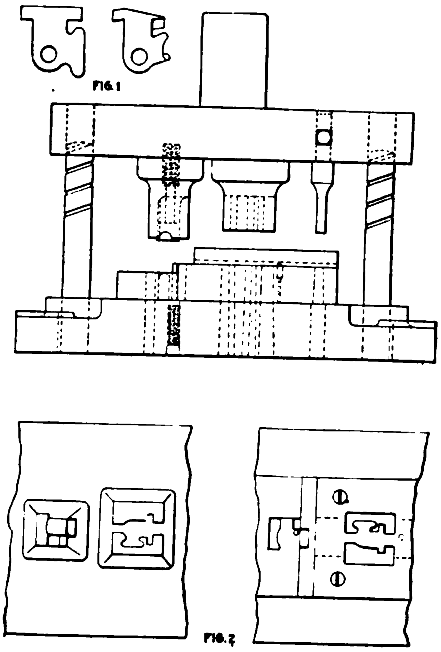
We used a mixture of turpentine and No. 00 powdered emery mixed to a liquid paste. The lapping compound was fed in from the hole in the tube and gradually worked itself out of the small holes. N. J. MIANO.

Norfolk, Va.

Discussion of Previous Question

A Simple Hand-Operated Bending Tool

On page 513 Mr. Breitschmid illustrates and describes a bending fixture for forming the small-sheet steel stamping shown in Fig. 1, which is first blanked and perforated on a power press. Although this bending fixture may suggest ideas in other lines of work, I cannot understand why it was necessary to go to this expense in order to form the stamping shown. The addition of simple forming parts to his blanking and perforating die would enable Mr. Breitschmid to complete this article in



PIERCING, FORMING AND BLANKING DIE

one operation. Even if made in very small quantities, a one-operation die of the progressive type, Fig. 2, would have cost much less than the blanking and perforating die plus the bending fixture.

Mr. Breitschmid states that fixtures of this character are of more than usual interest at this time on account of the great amount of work being required of power tools. This may be true in other lines of work, but in his case the addition of forming parts would not decrease the production in the operation of his blanking and perforating die, if the die was properly designed; and I fail to comprehend his meaning when he states that the hand-operated bending fixture requires only unskilled labor. Surely the operation of a small power press requires no better class of labor than that of hand-operated bending fixtures.

The die shown would eliminate the slow hand operation entirely. We have a great many dies of this type in service, some of which produce stampings very similar to the one Mr. Breitschmid illustrates. Others blank and form in a much more complicated manner by the use of cam-operated die parts, and nearly all of these dies will operate as rapidly as plain blanking dies, on an inclinable press.

If Mr. Breitschmid has many more of these parts to make, a die similar to the one shown would perhaps pay for itself.

South Bend, Ind.

Why Not Give the Applicant a Square Deal?

Reading Thomas B. Bracey's article on page 564, Vol. 43, reminds me of an experience of my own. Some time ago I answered an advertisement for a toolroom foreman. It required applicants to state age, nationality of parents, experience in full, names of last two employers, salary expected and to address XYZ office.

I replied, giving my family history, business experience and all other information asked for. Three weeks later I received a notice to call at the labor department of an out-of-town concern between 11 and 12 o'clock the next day. So 11:05 found me in the office in a more or less skeptical frame of mind, with three applicants for work ahead of me who, I learned later, were applying for the same position. After waiting a few minutes while the three clerks and the office boy gave me the "once over," I was handed an application blank designed to get a man's pedigree from the cradle up. Then my eyes fell on a framed notice that read, "Applicants not giving information asked for will not be considered."

In an hour and a half my turn came for an interview, which amounted to a cross-examination almost rivaling that to which a criminal suspect is subjected. After being ushered into a private office, I was seated between two men, one of whom I presume was Mr. Hiring Agent, the other the works manager. This is only a presumption, as neither introduced himself. However, I was not yet comfortably seated when they began to fire away—one putting the questions, the other cross-examining as to my truthfulness regarding the statements in my letter and application, which they had before them—and meanwhile writing down their impressions. They finally summed up by asking me how soon I could report in case they decided to hire me.

Up to this point I seemed to make a fair impression; but as I had begun to consider the situation seriously, I felt that I was entitled to know something of my prospective employers too. So I asked permission to put a few questions, at which they acted somewhat surprised, but consented. They balked, however, at my questions, which were: "Is this a new department; if not, why do you need a new foreman? Was the previous foreman promoted? Did he leave or was he discharged? Why? What was his salary?"

They decided I would not suit, whereupon I demanded the record they had obtained. They flatly refused to

surrender this, saying that it was to be filed away for future reference.

Has any business concern any right—legal, moral or otherwise—to keep a record, which in some instances is very personal, of a man who is not, never was and is never likely to be in their employ? WALTER HURLEMAN.

Philadelphia, Penn.

Over-Safetyized Machines

On page 371 Mr. McDermid discusses over-safetyized machines. This brings to mind an incident that happened in one of the Government navy yards.

When the fever of placing guards on machines struck the metal shop, all moving parts, approaches to punches and guards were painted a glaring red. Over each machine was hung a huge red and white sign, telling what to do and what not to do. It seemed impossible for a workman to be injured, unless he were blind or one of the "safety-signs" fell upon him. And that is what actually did happen. This accident was due to no fault of the operator nor yet to unprotected machines, but to "over-safetyization." The sign had been insecurely fastened.

The incident caused considerable joking among the men in the shop and about the yard, and the statement went around that the only way to get hurt in that shop was by a safety sign itself. CARL G. PLANCK.

Charleston, S. C.

Wanted--A Lighting Gage

I read with much interest your editorial on page 654, dealing with the lighting of factories.

I was at one time engaged by the largest rubber-producing corporation in the world in the attempt to reduce or abolish certain wastes of time, material and power that were taking place in its largest plant. The indifferent mental qualities of some of the laborers made it a difficult matter to impress upon them the importance of eliminating the waste, for instance, of lighting current, although this waste became an important factor when spread over the entire plant.

I suggested that the heliostat used in the automatic buoys common in our waters be adapted as a unit to cut in and out the lighting for whole floors or sections of floors where the average light requirements were the same. I even went so far as to consult with the engineers of the firm making these buoys and was told that, while the idea was new to them and they had no such apparatus ready for the market, there was no reason why the plan would not work.

It was planned to put one of these light-sensitive units at such a point that the minimum daylight necessary for the proper handling of the work would control the lighting circuit for that section. As soon as it became sufficiently cloudy or late in the day, the unit would automatically throw into circuit the lights or ring a bell as a signal to the proper person, whose duty it would be to attend to it. If good judgment were used in locating this unit, there would always be available current for lighting use; but it would not be possible for a careless employeee to leave his drop burning in full daylight. Since these units in buoy service are sufficiently sensitive to operate when the sun is suddenly obscured by a cloud or a fog, it is easy to see that they would be sensitive enough for factory service, especially if, as probable, a special adaptation were made.

The foregoing suggestion does not, of course, dispose of the cases where a special drop is used to examine work in process, but such conditions are nowadays carefully avoided by efficient superintendents and lighting engineers. ROBERT G. PILKINGTON.

Chicago, Ill.

Side Shields for Emery Wheels

W. B. Greenleaf states on page 606 that there is nothing in the composition of the wheel to prevent side grinding. This is true, but from my experience covering several years as a grinding-wheel salesman I am convinced that it is poor practice habitually to use the side of the wheel. It is a recognized fact among grinding-wheel manufacturers that a wheel for side grinding should be considerably softer, speed for speed, than one used for peripheral grinding.

Let it be assumed that we are using a tool-grinding wheel 12 in. in diameter, running at the correct speed for this size. For the dry grinding of general tools N grade is usually considered to give good results. When we grind on the side of the wheel, it glazes readily owing to the fact that the speed is far too high for this kind of grinding. Then we true the wheel at frequent intervals, which soon wears it out of shape, as the dresser cannot be brought very close to the collar. The result is a taper-sided wheel with its periphery half cut away from frequent truings. Such a wheel is a poor compromise, to say the least.

If the wheel was of a soft enough grade to do side grinding in a satisfactory manner, the periphery would be too soft. In other words, it is almost impossible to strike a happy medium. To be sure, if the workman exercises care, satisfactory results can sometimes be obtained. This in all probability was Mr. Greenleaf's experience. Where there is any amount of work that requires grinding on the side of the wheel, it is the best accepted practice to order cup wheels in a suitable grade for this purpose. With this type of wheel the dresser can be passed clear over the rim of the wheel, thus preserving a true surface. This plan not only insures good work, but it is the most economical practice in the end. The only excuse for grinding on the side of the wheel is where the shop refuses to purchase a cup wheel or a disk grinder. Many do not seem to realize that it is false economy to save the cost of one wheel at the expense of another. Moral: Don't expect too much of one wheel. F. B. JACOBS.

Indianapolis, Ind.

Who Can Make This Nail?

It is not so very long ago—before wire nails came into general use—that all malleable-iron plants made their own nails for flask boards and for general shop purposes. Why not cast the nail (referred to on page 604) of a good grade of malleable iron? A suitable molding-machine plate could be made for less than \$100, whereby one molder could easily produce 125,000 of these nails per day. A. E. HOLADAY.

Naugatuck, Conn.

Industrial Preparedness from the Engineer's Viewpoint

SYNOPSIS—A continuation of the discussion brought out at the New Orleans meeting of the American Society of Mechanical Engineers in which many practical pointers are made in connection with the manufacturing side of munition work.

Listing Engineers According to Previous Experience

By George R. Henderson

The point brought out by Mr. Miller that for each man at the front three are needed at home to prepare munitions of war is a most interesting fact. This is especially significant to those who through age or physical disability are prevented from entering the trenches or submarines, and it seems to me that in organizing for industrial preparedness the engineer who may not be directly connected with a manufacturing plant should not be overlooked. There are in the membership list of this society many who act in a consulting capacity, whose technical services would probably be of greater advantage to the national Government than digging trenches or shouldering a rifle. I believe these men should be listed, with their professional records, so that the very best use might be made of their services in the navy yards, arsenals and other plants where mechanical skill is of the highest importance.

I would suggest to the American Society of Mechanical Engineers representatives on the Naval Consulting Board that they consider this feature as well as that of mobilizing factories with their men and machines, so that all patriotic citizens would have the opportunity to serve their country in time of need in a manner which would insure the greatest efficiency of the organization as a whole and which would permit those who could not stand the rigors of active service to furnish their quota of usefulness by preparing ships, machines, etc., for those whose duty it might be to fight them.

Redesign Munitions To Reduce Cost of Manufacture

By Bernard M. Fine

The subject of industrial preparedness, while falling within the engineer's scope, should interest us also as citizens. As citizens we will have to meet the cost, and one good way to reduce it is to apply consolidated engineering experience to this problem and endeavor to put the design and construction of war material upon a basis similar to that customary in the commercial field.

In order to get production on the foreign contracts the limits had to be changed. This is too much like swapping horses in midstream. The time to do that is now, and it is really within the range of the American Society of Mechanical Engineers' work to assist the war office in modifying its standards.

To store in times of peace an amount of material equal to the needs of war would not be wise, but in times of peace let us educate ourselves to be adequate to meet this need. In war as now waged the industrial force plays as important a part as the fighting force. The industrial force must be officered by men trained in the peculiarities of munitions manufacture. This is the work of engineers, and the American Society of Mechanical Engineers should make the organizing of these men its business under an ordnance section and keep alive the work by requesting the presentation of papers on the subject at our meetings.

The delay that was occasioned in starting on foreign war orders was due to the fact that the contractor accepted orders for which his machine-tool equipment was inadequate, and the abnormal demand could not be met. As a result many, in order to escape penalties, pressed into service anything that resembled a machine tool, adaptable or otherwise, then improvised crude fixtures—all at great expense and delay. We can avoid this deplorable condition by means of Mr. Miller's system of cataloging adaptable equipment. We will then be sure that a contractor gets orders for only such component parts as his equipment will handle and in that way obviate the confusion and loss of time the foreign contracts caused. A central assembling plant, or a number of them, and an efficient inspection and supervisory force are necessary; but if we start now and line up the men adapted for this work, or even if we can get the war office to take these steps, we will have rendered the nation an invaluable service.

We have appointed a Publicity Committee to bring the work of the engineer into public view. Here is a chance for the committee to get busy and for the society to do work that will act as its own press agent.

I also wish to call attention to the fact that, with few exceptions, our munition plants are concentrated on the Atlantic Coast. This is in itself a danger, and steps should be taken so that in an emergency the work could be shifted to any section. Here is another instance where the ordnance section of the American Society of Mechanical Engineers would render invaluable assistance to the nation.

Preparation for Manufacture of Military Rifles

By Fred E. Rogers

A very large munitions plant would be required to run steadily for a year to turn out the shells fired by the Allies' guns in one day on the western battle-front. To provide the millions of shells used by them has required the united efforts of thousands of manufacturing plants. But these plants had to be provided with drawings, tools, gages, jigs and fixtures and plans of operations before they could begin to produce. It has been due to their lack that Great Britain has been so slow in getting ready.

Take, for example, the manufacture of military rifles: This is a complex process requiring special skill and experience. With the exception of our Government arsenals, there was at the outbreak of the present war perhaps not one plant in the United States properly equipped and manned for manufacturing military arms that would pass the rigid test prescribed by Government inspectors. There are about 800 principal machine operations involved in making the parts of the simplest military arm, including the wooden stock and hand guard. Many of these operations require special machinery, and practically all the parts must be held in jigs or fixtures during the machining operations.

When we consider the fact that, to provide for an army of 1,000,000 men, from 2,000,000 to 3,000,000 rifles are required, the size of the task of equipping an army of a million with shoulder guns alone becomes apparent. What the condition of this country would be in a sudden emergency, we can only guess. Judging from the experience of some of our ill-advised manufacturers who undertook to make shells, it would be one of great confusion and enormous waste.

Nothing can be left to guesswork. Every machine operation must be specified and the types of machines and tools; the production per hour is given and the number of machines that each man operates, etc. But no data are given of the jigs, the limit gages, the inspection or assembling. Several hundred jigs are required for each unit of a plant producing 200 rifles daily, and the same applies to the gages. All these data must be prepared by experts, but considerable experiment is always required before satisfactory results can be obtained. That such elaborate plans pay is known from the fact that a rifle, complete with strap, bayonet and scabbard, can be produced with about 20 man-hours' labor. Thus, while it is true that the means of production of munitions are in our machine shops, mills and factories, they must be supplemented by the drawings, specifications, jigs, fixtures, tools and plans of operations. These latter can be made ready for immediate distribution to the plants selected for each specific product.

Comprehensive plans should be prepared for the manufacture of shrapnel, high-explosive shells, cartridge cases, rifles, field guns and all the varied equipment of war. Every step of the operations should be laid down, specifying in each

instance the tool and the machine on which the work should be done and the limits of accuracy required, including an estimate of the possible production. It will be a great undertaking, but how much better it will be to spend a few million dollars working out plans to provide means for industrial mobilization and rapid production than to run the risk of a complete smash-up in time of stress. Perhaps in some cases selected plants should be required to produce some parts, even though only a few are made. When these parts have been actually produced, there will be in that plant a knowledge of the conditions and methods that should not be speedily forgotten.

It is true that all plans, tools, jigs, fixtures and methods of operations will become obsolete when improvements in the means of production and arms are developed, as they certainly will be; but is it not better to face this certainty and be ready to reconstruct the means of production and keep them up to date rather than to spend several hundred million dollars in the manufacture of those munitions, which themselves become obsolete and practically worthless in a few years?

There is an argument for this sort of preparedness which should appeal to every engineer whether he is in favor of military preparedness or not. It can be made a powerful lever for improving industrial efficiency. It is unfortunately true that many of our manufacturing plants are working far below their possible efficiency. They employ penny-wise and pound-foolish methods of production; their men are not trained to understand the basic principles of interchangeable manufacturing. Gaging systems are inadequate and incomplete; data on the life of gages are wanting as well as the number required for any given unit of production. There is too a lack of the coöperative spirit so absolutely necessary to success in any great trade or military emergency. Those emergencies will surely come to the United States, though, we trust, in the trade sense only. It will be only when we have coöperation in the true industrial sense that we can face with confidence great national emergencies.

Prevent Unnecessary Waste of Materials

By Percy E. Barbour

There have been many instances of great waste. How much of this waste is avoidable? The idea that there is a good deal of unnecessary use of metals by military men through thoughtless specifications is not new. A ray of light upon this subject is found in a communication from France, in the New York "Sun":

> A weeding out of unnecessary governmental expenses takes place in the Chamber of Deputies every year when the report of the Audit Office is distributed to Parliament. Usually a score or more of conspicuous cases in which the public money has been wasted are selected by a committee which investigates them. A member of the Committee on Economy spent several hours endeavoring to find a reason why ammunition was sent to the front in zinc-lined cases. The other members of the committee and the Minister of Munitions were not able to solve the problem, so two members of the committee accompanied a box of cartridges from Vincennes to the front, to ascertain the reason for the zinc. None were forthcoming, but after numerous fruitless interviews with army officers the general in command of the Fifth Army hit upon the reason. The zinc had been used for 60 years in ammunition boxes, and no one had ever thought to take it out. As a result an order was issued doing away with the zinc lining. As the zinc in each box is worth nearly $2, the saving during the war amounts to almost $150,000 a year.

Regarding this matter the "Engineering and Mining Journal" says editorially:

> In our opinion this indicates the most effective way for the engineering societies to render assistance to the military authorities of the United States. The measures that are being taken in the excitement of the present moment are largely at sixes and sevens. They are not laid out according to any definite plan. The logical way, we think, would be something like this:
>
> "The army general staff should determine the number of men to be put into the field in the worst possible contingency. No doubt it has done that already. It should draw up a complete bill of material for the supply of such an army. Perhaps it has done that, and perhaps not. That bill of material, together with specifications, should then be referred to the United States Naval Consulting Board, representing the engineering societies, and by it should be cut up and distributed among the engineering societies—the metallurgical parts to the metallurgical engineers, the mechanical parts to the mechanical engineers, the chemical parts to the chemists and so on. Those bodies would then subdivide things among their specialists. They would scrutinize the specifications, finding out whether certain things likely to be troublesome or costly were prescribed by reason of necessity or by reason of tradition. They would suggest substitutes and improvements. Having determined what was really needed, they would formulate plans for the supply of it, making a survey of the industries, listing industrial plants, etc., and recommending steps for the filling of gaps."

Recently a lot of barbed wire for military purposes was condemned by the inspector because the galvanizing was not even and smooth. This is certainly a ludicrous refinement, which can only militate against military efficiency in every way.

Organizing Men for Munition Manufacture

By James A. Campbell

Members of the American Society of Mechanical Engineers employing collectively several thousand mechanics could get signed statements from those men who would be willing in time of war to take positions in the large shell factories or wherever machinists were required. These mechanics could be classed by their superintendents so that firms requiring men could see from the lists the experience and class of workers available. Committees could be formed for the drafting of these men so that there would be no loss of time in the production of munitions.

Value of Good Roads in War

By John Younger

A nation in arms is two vast bodies—one the fighting unit, the other the producing unit. My experience has shown the tremendous importance of a third unit, the connection between the two—the transportation unit.

The production of any country is of little value if the transportation facilities are not ample to carry it. It must be remembered that in time of war the actual munitions will in general travel one way—toward the theater of operations. In time of peace Buffalo, for example, exports by means of its railway systems to the four points of the compass. Because of economic reasons these systems are proportioned in close accordance with the volume of traffic; and actually just now, when there is an exceptionally large volume of freight passing through to eastern ports, the transportation facilities are found inadequate and freight embargoes are operative on practically every railway.

We are exporting only a small percentage of the supplies used on the European battlefields, yet our transportation has not proved equal to the task. The building of more railways in our immense territory would be at a terrible cost that would render no adequate return in times of peace. Even if they were built, their use would be of value only in very restricted areas. Germany, France and Russia had all built strategic railways leading to and paralleling their frontiers, but they did not stop at this. They also built good roads. They knew that every ton of freight carried on the railroad is sometime or other carried on a road, and they took the precaution of having the road as efficient as the railroad.

Good roads are no luxury. They are not built for the motorist, who takes a week-end spin for personal enjoyment. They should be built to link up the small villages, the communities and townships with the railway and the big city. A good road opens up new country to the farmer, who can carry his produce to market at a cheaper rate. A poor farm located on a good road is often a better investment than a good farm on a poor road. A good road is an economic investment in time of peace, and it is a sign of the times that the country is waking up to facts.

In war times the roads are the first and last links in the transportation scheme. They carry munitions to the railway, and they distribute supplies from it. Each link in the chain must be of adequate strength. It is useless having a perfect railway, if it begins and ends in a bog. It is useless having stretches of perfect roads in New York State, if they be totally unrelated and unconnected with each other.

Great Britain, France, Belgium, Russia and Italy have bought from us vast numbers of motor trucks. They have been making others themselves, by the thousands, and still the supply is not adequate. Figures are not available, but I would estimate that France alone on actual military service is probably using 50,000 motor trucks. A vast army of men is kept exceedingly busy making and repairing her roads. Actually, munitions are being put on motor trucks in the industrial centers of England and carried along the roads to the desired port; thence the truck travels by steamer and completes its journey along the roads to the base depot.

The organization of our transport demands the attention of our engineering bodies just as much as does the

mobilization of our industrial resources. The standardization of our road systems, the standardization of the controls on our locomotives and motor trucks, so that men can change from one to another with all confidence, the education and disciplining of numbers of men to the principles of transportation are all matters that can be handled by engineering executives only.

Standardizing Gages and Fixtures

By Harold V. Coes

It seems to me that one of the vital elements necessary for the proper carrying out of the plan is for the Government to construct in its own factory under its own jurisidction and in accordance with its own standards the necessary jigs, templets, gages and fixtures that are required and that are adaptable to special or standard machine-tool equipment. Then the Government should rent, lend or sell these tools to those manufacturers who are equipped, and who signify their intention, to manufacture shells, rifles and other war material of this character for the Government.

I think there is no doubt that the British Government in its present crisis would have been much farther ahead with its plans if it had been able to send necessary jigs, templets, gages and fixtures to those manufacturers in this country who are making munitions of war for the British Government. The jigs, tools and fixtures that rifle manufacturers in this country use were of practically little use when it came to making the Lee-Enfield; consequently, it would appear extremely desirable for us to profit by this lack of foresight on the part of one of the powers now engaged in the present worl cataclysm.

Co-operation and Standard Methods in Shell Making

By Ralph Flanders

There are a number of points in connection with the experience of Canada which I think would be useful in our own situation. The first point noticeable was the difficulty of getting gages, and this difficulty was serious. It was necessary to try to get the shells out in a few weeks, but usually several months were required. A larger number of gage-making machines had to be undertaken than was reckoned with at first.

Another difficulty met with in the manufacture of Canadian shells was the lack of means for furnishing the material and supplies. It would be the same as if in a manufacturing establishment one department should get way ahead of another department. For instance, if the makers of the shells are many months ahead of the makers of the fuses, there is delay; and sometimes a fuse is held up for a small screw. There should be some committee to attend to such factors as that—what you might call routing of the work, to make sure that each department gets through with the work on time and to put all the energy possible behind the departments falling behind.

Another exceedingly favorable feature in the Canadian manufacture of munitions was the publicity and the co-operation shown there. There were absolutely no secrets in the shops of the Canadian manufacturers. That was made a requirement of the shops—that everyone who desired to engage in the manufacture of munitions was privileged to see what everyone else was doing. While the whole country was ignorant of, and unprepared for, the making of munitions, yet in a remarkably short time everyone was able to know what everyone else knew. In regard to that matter I think that we are in a somewhat bad condition in this country, or we should be if similar conditions were brought about. As a natural thing where ammunition is manufactured in private plants, we find that the processes of manufacture are kept quite secret and visitors are not allowed. This is the case at the present time at the plant in Philadelphia, unless conditions have changed in the last few months, and it is a bad state of affairs. It is not necessary that an arsenal should be thrown open to everyone, but it is necessary that everyone who may be called upon to manufacture shells may use whatever the Government arsenal has to offer.

Another thing to be noticed in Canada is the impracticability of standardizing methods. I am speaking of shrapnel and high explosives. I do not think the same statement applies to small arms. The demand for machine tools is so tremendous that it is impossible to approach the problem from an ideal standpoint. It is a question of adapting processes to machines that can be used and have to be used, and different kinds of tools have to serve in the different machines. For instance, take the operation of finishing the inside of the shell. That has been done on a lathe, on an automatic turning lathe, on standard machines, on drill presses and on special machines made for that purpose. It would be folly to confine the method of doing that work to any one machine and leave the resources of other machines untouched. So I am inclined to think that we should go a little slow in the matter of standardizing too finely the process of making shells, as thereby we should cut down the rate of production.

Another interesting point is the improvement in design and manufacture. This is a subject to which there are two sides. I think that a manufacturer or a machine-shop man who undertakes ordnance or munition work is beset by a large number of foolish provisions and unnecessary requirements regarding methods of manufacture. He is likely to find after he investigates the matter a little further, however, that they are not entirely foolish. They look foolish to him because he does not understand all the necessities of the case. There are a few instances, however, where it is possible for the ordnance designer to come more into line with the manufacturer, as in the case where the manufacturer has to swing into line making ordnance.

One point that I might mention is when the shell shall be treated. The method now followed in the average arsenal is to treat the shell in the blank immediately before the forging is done. It has been found, so far as the English shell is concerned, under pressure brought to bear on the manufacturers that it is possible to leave the heat-treating of the shell until the final finishing operation on the outside; and it would be well for the United States Government to provide for this, if it has not already done so, because it means an increase in the production of shells.

There are rumors of bad management in Canada, from the standpoint of excessive profits to certain firms and individuals. Such a condition might be true in our country and might be discovered more quickly than it was in Canada. So some such provision as is suggested by Mr. Miller would be necessary; and this would necessitate something in the line of a standard method of accounting, having some way of defining the various details of manufacture and the methods of manufacture. Depreciation should be reckoned, and the various items that go into the overhead should be calculated. The requirements should be quite simple and should be readily taken care of.

Pressures Used in Drawing Cartridge Cases

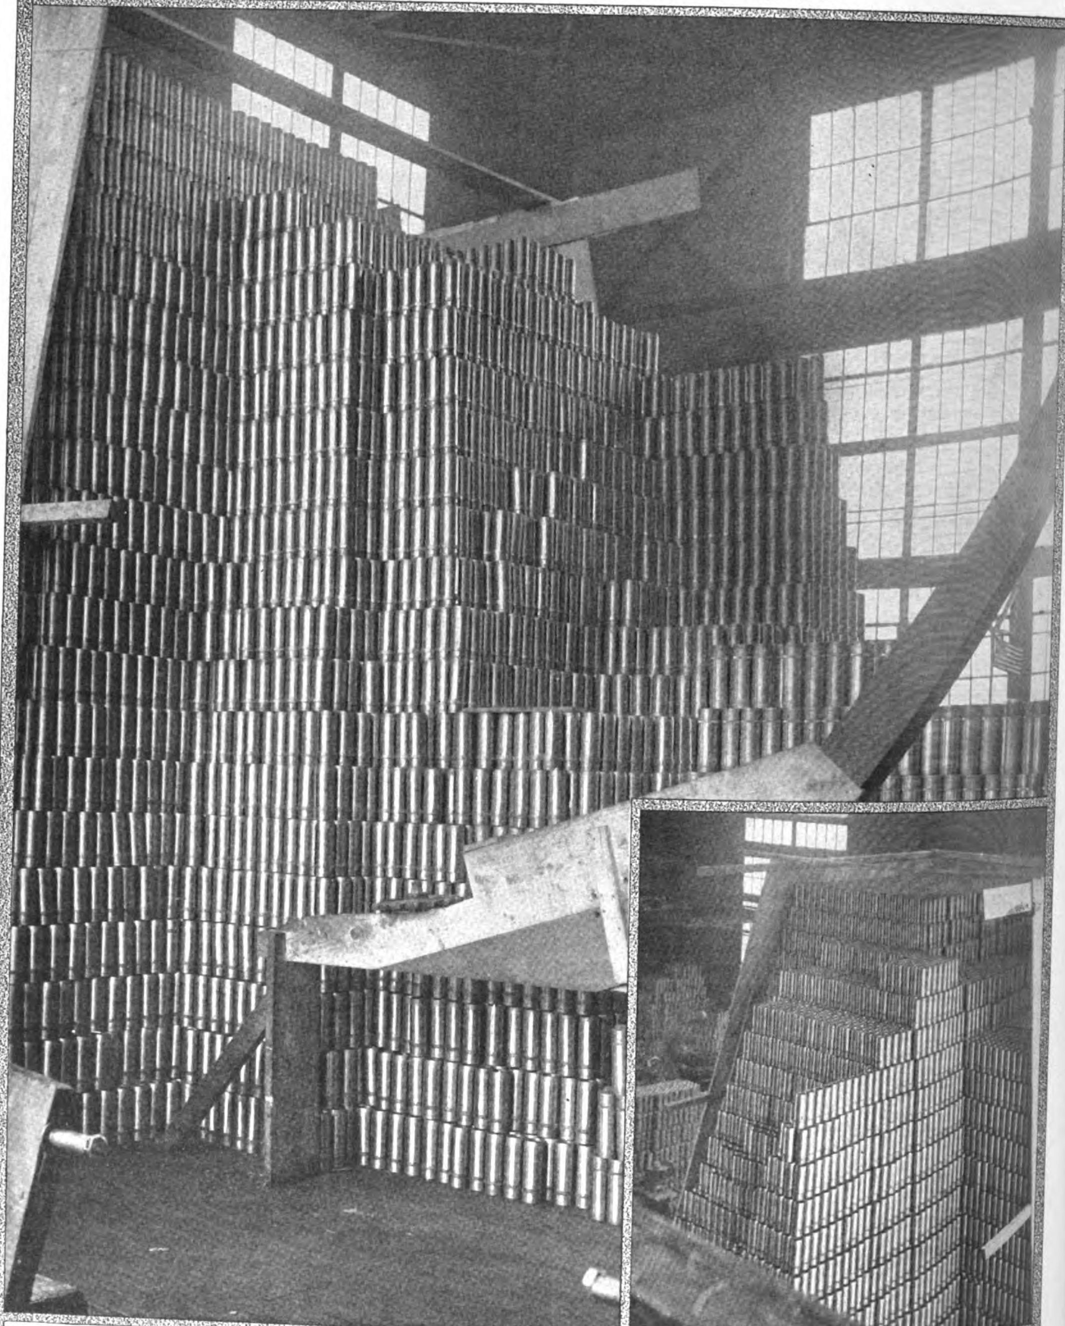
By Oberlin Smith

One very important class of machine tools was no. ...entioned in the paper by Mr. Miller—the presses with which cartridge cases are made, the brass cases up to 6 or 8 in. in diameter. The most important size is known as 3-in., or as the 75-mm. shell in France. More of those are used, probably, than of any other kind, and a great many American presses have been built for making the British 18-pounder—about the same size.

The cases are drawn in from six to nine operations, the 3-in. in presses giving 100 tons' pressure at first. They cut the blanks from sheet brass, usually about ⅝ in. thick, draw them into cups, by successive draws, down to an edge $\frac{1}{16}$ in. thick. Millions of these cases are being made, and thousands are spread over the battlefield of Europe every day. The operations are usually with 100 tons' pressure until the cases reach full length, and then they require 1,000 to 1,300 tons' pressure to squeeze the head, which is left full thickness, into the same shape as the small cartridge. The cases are almost all being made in presses already standardized. The presses themselves are almost exactly the same as have been made for years by the different press makers for all sorts of drawing work and all work of that nature.

Besides the presses for making cases there are some used for punching and drawing the steel shells, although a great many of the latter are cut from solid bars. The last drawing operations on the brass cases is often done in hydraulic presses, but lately sizes up to 3, 4 and 5 in. have been made chiefly in mechanical presses. The presses for long strokes also have their place.

Twenty Thousand Shells Waiting For Fuse Sockets



In shops producing thousands of shells daily the shortage of one component part causes a delay and accumulation that run into money.

Editorials

Delays That Mean Money

The accumulation of shells shown in the illustration on the opposite page is due to the shortage of a small component part, which is a few days' late in its arrival at the factory. Anyone can see at a glance that an accumulation of this kind means men, machines and money tied up—a disruption of organized effort that becomes serious in a very short time. It means a dangerous condition unless promptly acted upon by the company's officials.

Invisible dangers are much more to be feared than visible ones. In a shell-producing plant where shells form the exclusive product a condition of this kind cannot escape attention. The slightest interruption of regular routine or a shortage of component-part supply calls attention to itself immediately. There is but one main consideration—shells; there is a shortage of but one part—in this case, fuse sockets; the result is accumulation and congestion that begin to be seen in a few hours and continue to grow until they assume mountainlike proportions unless the cause is removed.

The shop that is not working on shells, but has a large variety of products, encounters this danger in a more insidious form. Shortages do not make their results apparent in such a striking manner, although their total effect, distributed over the many products made, may tie up just as much money. It is hard to grasp this fact, because the human mind cannot conceive the meaning of an immense variety of unlike objects and parts, as it can easily do with a quantity of exactly similar pieces, such as shells.

The average shop doing a great variety of work is marked by the large accumulation of product parts, and one having a clean floor is an exception. There is but one unit by means of which this accumulation can be translated into a realizable total, and that unit is the dollar. Plants that have a running inventory of work in process have a gage which will indicate the effect of delays quickly and accurately. Those that have not should study the illustration of this accumulation of shells and draw a profitable conclusion from it.

Avoiding Costly Errors in Indexing Work

The problem of accurate and reliable indexing on millers is a serious one in manufacturing products that require uniform spacing. Gear cutting is of course done by automatic indexing, but such work as reamers, milling cutters, etc., is not usually indexed in that way. The dividing head as applied to a modern miller, with its gearing for compound and differential indexing, works out admirably in the toolroom, but seems to leave some things to be desired when it is used in regular manufacturing work.

As an illustration we may cite an instance of an operator running four machines, each doing a different kind of work. The indexing varied from four to fourteen divisions of the work. With the geared dividing head this meant a different number of turns, in addition to the different fractions included between the fingers of the sector, although this feature should not be confusing. The main trouble comes from the varying number of turns for each dividing head.

With four heads to attend to, all with different indexing, together with the desire to do the indexing as quickly as possible and so reduce the idle time of the machine, it is small wonder that mistakes occur. Few of us could probably do much better in the long run, day after day; it is so easy to make one turn too few or too many. But the loss of nearly $900, covering a period of only 30 weeks in one particular shop, due to errors in the milling department, makes us feel that some sort of remedy should be forthcoming at an early day.

Two solutions seem to present themselves, aside from the question of automatic indexing, which might not be considered feasible in many cases. One, which seems to be the most practical, is to use direct indexing for such work. This can be easily accomplished on some dividing heads by dropping the worm out of mesh and using an index plate on the spindle, as with plain indexing centers. This plan would obviate any difficulty as to counting turns, the movement of the index pin between the sector fingers being all that is required, which could hardly be confusing.

Another solution, which is neither as simple nor as easy of accomplishment in most cases, would be so to plan the work that the same operator need not index different divisions. This arrangement is not easy, yet it might be possible in some instances where the dividing heads were incapable of being used for direct indexing; for $900 would pay for considerable readjusting of machines and work and is well worth considerable effort to save. And where no other way seems to be at hand, there can be no doubt that the work should be so arranged that a man does not have to make widely varying movements in indexing, with the ever present opportunity for error thus presented.

Special index plates, or at least plates that permit direct indexing by means of the sector, seem the most practical method of solution.

Some Changes Needed in the Consular Service

As American manufacturers are seriously engaged in reaching out for export trade, it is appropriate to suggest needed changes in the consular service in order to make it an efficient aid in business getting. The changes here suggested are inspired by questions asked by American manufacturers in response to circular letters sent out by the *American Machinist* and *Engineering News*, asking if specific information of any kind was desired on South American conditions. The inquiries in re-

ply came from all sections of the United States and Canada, showing that there was no section of the country more conversant with foreign-trade conditions than another. Extracts from these letters follow:

Is it necessary for a representative to have a knowledge of the Spanish language in order to do business there?

Please peruse our catalogs and tell us with what success these machines can be used in that country.

Please send us a list of reliable agents in each country.

What is your opinion of the possibility of selling friction clutches, friction-clutch pulleys and small friction-driven hoists there?

Please send us a list of users of our product.

My competitors are shipping at lower than publicly quoted freight rates. How do they do it?

What kinds of tools are principally used in the machine shops?

In what kind of manufacturing are ball bearings used?

We have had numerous inquiries from South America, but have been unable to sell. What is the trouble?

Is there a market for our machinery?

We are without authoritative information concerning trade conditions in South America. Can you enable us to enter this field successfully?

How much belt-hook business is there in South America?

Is there any market for gears there? Are any gears manufactured there and in what amounts?

What percentage of drills, reamers, cutters and tools of this character is of American manufacture?

Can sales to railroads and large industrial users be handled to advantage direct from this country?

Can we sell second-hand equipment there?

What kind of belting is used there; where made?

Are quality goods used, or is price the most important feature?

What about credits there?

What are the best means of marketing our products?

What are the future possibilities of that market?

What are the expenses for traveling?

Are factories equipped with bolt-threading machinery?

What is the buying procedure?

Would it be better to wait until war is over to go after that business?

What fields now developing present possibilities for the sale of our machinery, and whom may we approach regarding it?

How can I quote a delivered price under present conditions?

We have orders on hand held up by high freights. Is there any way around this?

On what class of work are they using turret machinery?

Send us specific information of the number of machine shops, classified as to kind, number of employees, etc.

What are the best methods of getting our product before consumers there?

Our lines comprise engines and boilers, 3 to 60 hp. mostly, also hydraulic turbines. Help us increase our business.

What are the terms of payment for water-purification plants, when bought by municipalities and individuals?

We would like to know whether our customers are worthy of credit.

Send us all available information regarding irrigation and drainage work and marketing of pipe at present time.

Please recommend reliable forwarding agents for handling shipments to this address.

What railroad developments or irrigation and drainage projects are under way?

We have an order on our books which has passed through two hands, each of them probably taking a commission. How is this usually handled?

What is the best way of forwarding small shipments?

Please send our catalog to the chief engineer.

What kinds of flare lights are used?

What are the legal requirements with respect to cast-iron pipe for house drainage, water-works, etc.?

Is concrete curbing used in South America; and if so, where and under control of what public officers? Are curb guards used?

To what extent is concrete-base or concrete pavement laid?

Is there a field for derailing devices there?

To what extent are creosoted materials used?

What classes of business use standard railroad-type shovels, small revolving-type shovels, drag-line excavators, dipper dredges, elevator dredges, hydraulic dredges?

The wide range of these inquiries suggests that the Government should consolidate its commercial forces so as to present accurate specific data in reply to any questions, American manufacturers may have available at all times industrial information to promptly meet the inquiries.

This implies a complete canvass of the manufacturers, merchants and consumers in every market of the world every five years or less. Every item of information that could be used by a manufacturer to increase his business should be noted. Complete details of the nature of equipment used in mechanical plants and factories should be given. Anything that will guide a manufacturer in the problem of increasing his business should be included. What a manufacturer wants is *practical* information, credit ratings, etc. Such information cannot be obtained in any other way than through inquiries on the ground. Dependence cannot be placed upon city and telephone directories and classified lists, as may be seen from the fact that the six largest machine shops in Rio de Janeiro are not in either directory.

The objection of the Government that a consul should not criticize can be overcome by putting his comments in the form of quotations from various authorities whose names need not be mentioned in the reports. A diplomatic representative is really handicapped by the courtesy expected of him, so that the consuls come nearer the actual consumers. Therefore, the bulk of this work should be handled by the Consular Service.

The pay should be higher than at present, to attract a better class of men, and they should be furnished with capable heads for the various trade departments. The weaker members now in the service should be transferred to other departments where their activities are not so closely connected with American prosperity.

Conditions are certainly ready for improvement when one of the largest manufacturers in the United States writes to the *American Machinist:* "We are without authoritative information concerning trade conditions in South America. Can you enable us to enter this field successfully?"

Duncan N. Hood, the representative of the *American Machinist* in South America, reports that he entered the United States consulate in a city of 120,000 inhabitants and asked, "How many machine shops are there here?" An aged Englishman who was in charge (the consul was on leave and the vice-consul had not yet reached the office) replied: "There is only one. It has a concession covering all repair work here." Mr. Hood found within four blocks of the consulate two machine shops working full blast, and there were eight in the city. One of them is larger than the shop the consular officer thought was the only one.

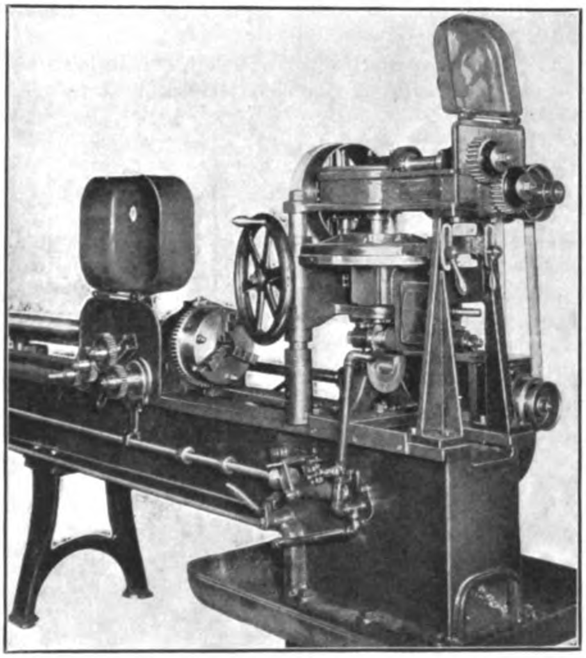
Intelligent and aggressive coöperation between the Consular Service and the technical press is highly desirable. The technical press knows by many years of experience just what information is needed and the best methods of acquiring and presenting it for the use of the busy manufacturer, while the Consular Service has the machinery for obtaining the facts. The start should be made now.

A correspondent of the *American Machinist* sent a clipping from the letterhead of a manufacturing firm and emphasizes this statement, "Makers of Special Tools—Tools of More Than 100 per Cent. Efficiency." He also adds this comment, "Some of us must be asleep." The *American Machinist* agrees with the comment, but dislikes to say just who is slumbering among dreams of something from nothing.

Shop Equipment News

A Thread Miller

The illustration shows a thread miller built by Edwin Harrington, Son & Co., Inc., Philadelphia, Penn., designed for a general range of work of milling screws, threads, slots and spiral gears, either right or left hand, of fine or coarse lead, either single or multiple. It will also mill keyways in shafts, flue rolls and perform many other similar operations. The work is gripped in a



THREAD MILLER

chuck at one end and is supported in a steadyrest directly under the cutter, thus avoiding the disadvantages of cutting work on centers.

The cutter head is mounted above the work, allowing full inspection of the cut at all times, and rotates 180 deg. on its vertical trunnions. The spindle is driven by helical gears and generated-tooth bevel gears. The drive to the machine is from a single pulley on the top frame, with six changes of cutter speed by slip gears.

The lead screw is large and mounted in direct line with the work, which is gripped in a chuck mounted on the end of the lead screw. The pitch of thread to be cut on the work is regulated by change gears on the carriage controlling the relative speeds of two worm gears, one revolving the nut and the other the chuck and screw. Indexing for multiple threads is accomplished by a special method that avoids errors of spacing and the use of special index plates. A wide feed range is provided by a system of belt cones and quickly operated sliding gears in a box. Any desired feed can be obtained from 19 in. per min. on the periphery of ½-in. work to 0.75 in. per min. on 4-in. work. When grooving straight or long spirals on rolls, the lineal feed along the axis of the work is from 0.015 in. to 3 in. per min. For this special class of work the machines can be furnished with special gearing to allow a faster feed.

Power-operated quick return is a part of the regular equipment. An indicator is also provided for picking up the thread after the carriage has been returned by hand with the nut open. Automatic trips are provided for both the feed and the power return.

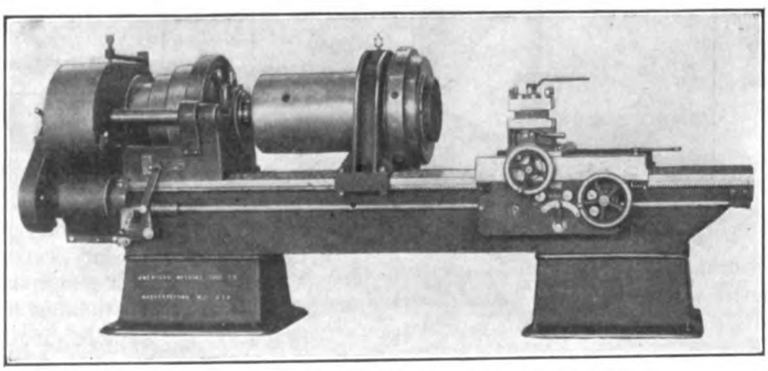
The bed is one continuous casting and is provided with a large drip pan and a settling tank for catching the chips and cutting lubricant.

The regular equipment includes an overhead countershaft, six cutter speed-change gears, fifteen lead-change gears, two steadyrest bodies, two steadyrest bushings, a heavy three-jaw chuck, a full set of wrenches and charts for change gears and multiple-thread indexing.

Heavy-Duty Single-Purpose Engine Lathe

While the lathe shown was planned to be specially adapted for turning and facing back ends of 12-in. shells, the requirements of a general-purpose lathe were kept in mind during its design and construction. It is claimed therefore that only a few slight changes will be necessary to adapt the machine to meet the more general requirements of lathe duty.

The headstock is of English design, in which the gears are placed in front of the spindle instead of at the back. A lever at the top of the gear case operates a pair of sliding gears running on a feathered sleeve that is attached to the cone pulley, providing two changes of spindle speeds. The form of the gear box eliminates the



HEAVY-DUTY SINGLE-PURPOSE ENGINE LATHE

Swing, 24 in.; spindle diameter, 5½ in.; hole through spindle, 2⅛ in.; length of carriage on ways, 31 in.; width at right angles to ways, 29$\frac{11}{16}$ in.; weight 7,570 lb.; length of bed, 11 ft.

need of a clutch. The hand lever is easily shifted to any one of its four positions. The lever moves a special key constructed with a heavy spring in a keyway under it, which is designed to insure the key's springing into proper contact. Hardened-steel rings placed between the gears cause the key to be pressed down below the surface of the shaft and pass readily from one set of gears to the other. With this arrangement four changes of feed—0.01525, 0.02343, 0.0325 and 0.0625 in. per revolution of spindle—are provided.

The bed is braced internally by four channel-shaped girts. The back side of the bed is flat; no V is put on it, except a small supplementary one to permit the fitting of a tailstock. At the front there is a special-shaped V planed to angles of 22 and 68 deg.

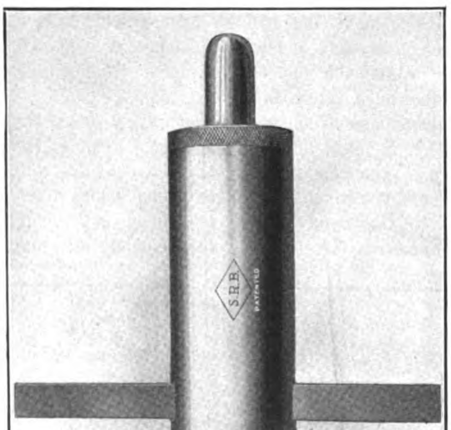
The power crossfeed is operated by throwing the lever in the apron to the neutral position and then pushing the knobbed shaft on the crossfeed shaft in as far as possible. This puts the crossfeed gears in mesh and throws out the rack gear.

On the carriage is mounted a standard-type 8-in. square turret. The revolving tool holder, having four slots, revolves on a steel tapered pin and has six locking spaces, thus allowing the operator to put his tools on a tangent or angle, if necessary. The locking arrangement is rigid, and the locking bolt can be adjusted to take up wear by means of a taper gib.

The machine is a recent product of the American Machine Tool Co., 50 Church St., New York City.

Portable Brinell-Method Hardness Tester

The growing demand for real knowledge regarding the hardness of metals has developed several instruments for that purpose, the latest being a simple portable device



BRINELL PORTABLE TESTER

Contains Brinell meter, 6 bars of standard hardness, 12 standard 10-mm. tools, 2 special scales, set of direct-reading tables, key for inserting new lots, instructions, leather carrying case 9¼x6¼ in.; weight, 6½ lb.

that utilizes the well-known Brinell method. This feature allows the instrument to be taken to the work and to be used on thin metal sheets that are apt to be penetrated when tested in the regular Brinell machine.

The simplicity of the device is apparent from the illustration. A standard 10-mm. ball is held loosely in the end of the body. Above it is a standard bar of square section, having a known degree of hardness. The ball is placed on the spot to be tested, and the plunger at the upper end is struck with a hammer of any convenient weight. By means of a special scale furnished with the instrument the diameter of the depression is then compared with the one made in the standard bar.

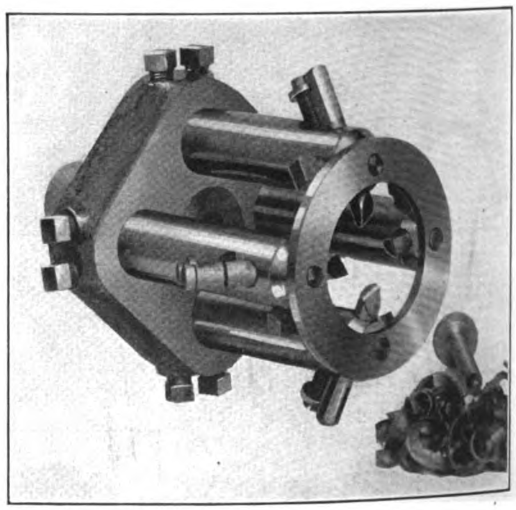
If the indentation is the same as that in the standard bar, the hardness of the material is evidently identical with that of the bar. Should it differ from the standard, a direct-reading table gives the hardness in Brinell values.

It will be seen that neither the weight of the hammer nor the blow struck is important, so long as a readable depression is secured. For thin metal sheets a light hammer is used and a softer standard bar inserted above the ball.

The device has much to commend it, and its distribution is in the hands of Herman A. Holz, 50 Church St., New York City.

Screw-Machine Box Tool

The main base of the body of the open-type screw-machine box tool shown is made of cast steel; the bars supporting the cutters, of machine steel; the cutters, of high-speed steel. The cutters are adjustable to varying diameters by the small collar and setscrew feeding in the cutting tool proper. The rake of the tool can be changed



SCREW-MACHINE BOX TOOL

by releasing one of the capscrews in the shank of the cutter holder and tightening the other.

The open-type construction permits free lubrication and chip clearance. Four cutting tools are provided, and the chip clearance, as well as the ease of lubrication, permits running at higher speeds and coarser feeds.

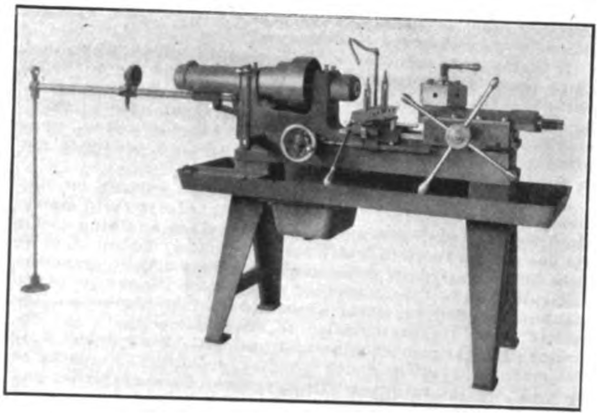
The elimination of the roller or block backrest is calculated to minimize friction, and four tools cutting at one time have the same effect as a roller backrest, insuring concentric work. The locking feature is positive, and the main tool adjustment is easily and quickly made. The main tool

holders are graduated for adjustment for varying diameters.

This tool is manufactured by the Watson Manufacturing Co., Toledo, Ohio.

Hand Screw Machine

It will be observed that the hand screw machine illustrated is of the conventional design. The manufacturer—the Loisy-Patton Co., Cleveland, Ohio—emphasizes the heavy headstock construction, intended to insure rigidity, and its dished base. The base is slotted so that the oil that drops from the bearings flows through to the drip pan instead of over the headstock sides.



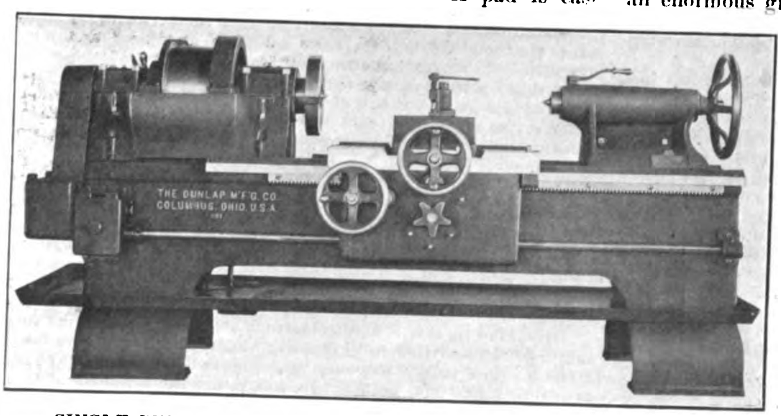
HAND SCREW MACHINE

Capacity, 1 in. rounds; length of turned stock, 6 in.; swing over bed, 14 in.; swing over cut-off slide, 6 in.; maximum distance from end of spindle to face of turret, 14 in.; hexagon turret, 1 in. holes; three-step cone drive, 3-in. belt

Heavy-Duty Back-Geared Engine Lathe

The illustration shows a heavy-duty single-purpose back-geared engine lathe built by the Dunlap Manufacturing Co., Columbus, Ohio.

The bed is cast from so-called semisteel that is cast iron with an admixture of mild steel. A pad is cast at the back of the bed and planed for the reception of taper, or forming, attachments. The headstock bearings are provided with ring oilers.



SINGLE-PURPOSE HEAVY-DUTY BACK-GEARED ENGINE LATHE

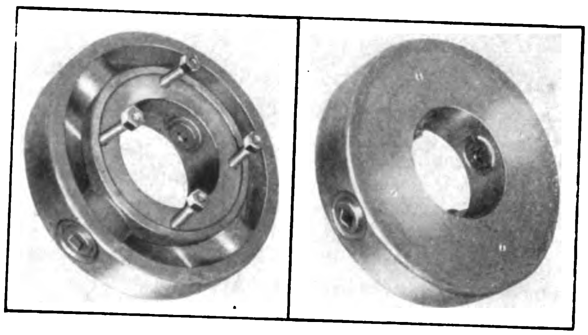
Swing, 21 in.; swing over carriage, 14 in.; distance between centers, 37 in.; driving pulley, 14 in. in diameter for 6-in. belt; bed, 8 ft.; weight, 6,000 lb.

The tailstock is a single casting. The clamping bolts are both in the center. The spindle is of forged steel. The end thrust is taken by steel and bronze collars. The carriage is cast from steel mixture and provided with taper gib to take up wear. The apron is of the double-wall type.

Seven feeds provided are from 0.012 to 0.112 in. per revolution. The feed gears are of steel, 8-pitch. The pan is of sheet steel. The cut lubricant pump is mounted on the rear of the bed. A two-speed countershaft is furnished.

Extra-Heavy Four-Jaw Chuck

The chuck shown in front and rear views in Figs. 1 and 2 and in detail in Fig. 3 is made in several sizes by the Mann Corporation, Chicago, Ill. It was designed to meet the requirements for an independent four-jaw direct-screw chuck with large hole and small range of jaw travel and is especially good for use on heavy cutting-off machines and for gripping shrapnel or high-explosive shells of all sizes during machining operations. From the construction it will be seen that an operator can get an enormous grip on the work with comparatively little exertion on his part, and when properly tightened the work will positively not slip under the heaviest cuts.



FIGS. 1 AND 2. EXTRA-HEAVY INDEPENDENT-JAW CHUCK

Specifications—Made in three sizes, as follows: No. 3, rated size, 12 in.; diameter of center hole, 4⅛ in.; diameter of faceplate seat, 5¾ in. No. 6, rated size, 18 in.; diameter of center hole, 6¾ in.; diameter of faceplate seat, 12 in. No. 9, rated size, 24 in.; diameter of center hole, 10¼ in.; diameter of faceplate seat, 15 in.; weight, 350 lb.

The body of the chuck is bored out quartering to receive shouldered sleeves pressed in from the inside. These sleeves are of large diameter and are threaded near the outer end for the reception of an eight-lead nut operating the jaw that slides in the inner part of the sleeve. A small key prevents the jaw from rotating as the nut is turned. The large diameter of the nut with its comparatively small lead, gives an enormous leverage when the wrench is applied for tightening. All parts are made of suitable material and properly proportioned for the hardest kind of service. It will be noticed that the hole through the chuck for the passage of work is very large when compared with the outside diameter of the body of

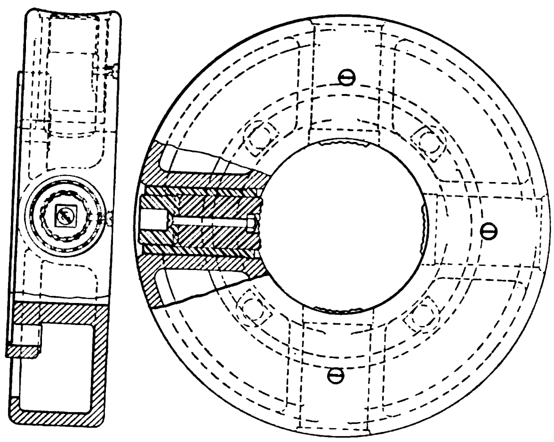


FIG. 3. DETAILS OF INDEPENDENT JAW CLUTCH

the chuck. This feature adapts the chuck for use for many other purposes besides the production of shrapnel and high-explosive shells.

Convention of National Metal Trades Association

The eighteenth annual convention of the National Metal Trades Association, on Apr. 27 and 28, was well attended. The first day was devoted to the regular business of the association, including reports of officers and of standing committees. These included Industrial Education, F. A. Geier, chairman; Apprenticeship, W. A. Viall, chairman; Membership, John W. O'Leary, chairman; and Prevention of Industrial Accidents, W. H. Van Dervoort, chairman. The afternoon was devoted to an experience meeting of members.

One of the interesting features of the morning session was the result of a referendum on the proposed legislation to compel the use of the metric system. The vote was 238 against to 37 for. The following resolution was unanimously adopted:

Whereas, The system of weights and measures long established in the United States and in all English-speaking countries has been attacked by numerous parties who are desirous of imposing upon American industry the metric system, and

Whereas, The Director of the Bureau of Standards has issued a report on the "Metric System in Export Trade," published as Senate Document No. 241, which gives an erroneous idea of the necessity of fostering the use of the metric system because of our participation in foreign trade, and

Whereas, Several bills have been introduced in Congress purporting to promote uniformity in weights and measures, but inimical to the long-established system, and

Whereas, The engineering industry comprising the membership of the National Metal Trades Association is vitally concerned in the conservation of the existing system and realizes that the fostering of any foreign standards means confusion to industry instead of promoting uniformity, and

Whereas, The several engineering societies participating in an intersociety committee to consider the feasibility of the adoption of the metric system following an agitation promoted by scientists and others not fully appreciating the vital importance of this question in its industrial aspects as well as in the habits of people; it is hereby

Resolved, The National Metal Trades Association in convention assembled deplores the continued agitation of a subject which would deprive American industry of a substantial uniformity heretofore enjoyed in its use of weights and measures and points with pride to a great foreign trade already secured by the ready adaptation of our products to the needs of the foreign buyer without any legal enactment or Government supervision, and be it

Resolved, The efforts of Government either through statutory enactment or through administrative action should be the promotion of uniformity on the basis of present universally used units instead of the encouragement of any new units, and be it further

Resolved, The sense of this convention be conveyed to the members of the Interengineering Society Committee, to the Committees of the House and Senate on Coinage, Weights and Measures, to the Secretaries of the Department of the Treasury and of Commerce and to the press.

F. A. Halsey then spoke as follows:

Superficially, the metric system is the most plausible thing on earth, and one must go below the surface to see its fallacies. One man wants it because he "believes in anything decimal"; another wants it for "uniformity," and another thinks it "necessary for export trade."

It is through such superficial generalitites as these that many make their decisions. The chief racket now being worked is the export-trade racket, as expressed by Hon. James L. Slayden, member of the House Committee on Coinage, Weights and Measures, at a recent hearing of that committee: "If we do business in South America, we have got to do it on that system."

Before this audience it is superfluous to enlarge on this topic, as you gentlemen know that your products go to metric countries where no one knows, asks or cares anything about the units of measure to which they are made. You may, however, be interested in some new facts that I take from the latest number of the "American Machinist." Many are aware that shortly after the outbreak of the war the "American Machinist" sent a representative to South America in the interests of American machine-tool builders. That representative made a circuit of South America, spending 18 months at the task; and he returned with a census of the personnel and equipment of South American machine shops, of which there are more than most people believe. This census shows that of the machine tools in South America 39.3 per cent. are of American, 43.2 per cent. of English and the remaining 17.5 per cent. of German, Belgian and French production, the total being 82.5 per cent. made to English and 17.5 per cent. to metric measure. We are always told that the countries of South America are solidly metric, the only exception being British Guiana. They have the markets of the world from which to buy, and no one in this audience will claim that German machine tools are not good tools. Nevertheless, these metric countries buy machine tools made to English measures, in preference to those made to metric measures, in the ratio of nearly six to one. We have here in brief the contemptible littleness of the export-trade argument.

But how plausible the argument sounds! This surface plausibility is characteristic of every claim made, and therein lies the danger. Yet prick these claims with commonsense, and every one of them collapses like a soap bubble, just like this one. There is no reason whatever for the adoption of the system; there is every reason for having as little to do with it as possible. The facts are all against the system, and they have been widely published. They are so conclusive that no one who knows anything worth knowing about the subject can possibly favor the system. But does this make any difference? Not the slightest. The metric party simply ignores all we say except when they add insult to injury and claim that our arguments have all been answered and our difficulties shown to have no foundation.

Of this I will give you a few examples, which are not the result of a search, but are simply expressions that have come under my eye during recent weeks when reading new metric literature. First, we have this choice example from Secretary of Commerce Redfield:

Recent practical experience has disproved so much that has been written against it that I venture to say that the Bureau of Standards is now in an excellent position to represent the enlightened opinion on both sides of the question.

Again, we have from Dr. Stratton's report on the "Metric System in Export Trade":

In the textile industry, for example, one outspoken writer —not a manufacturer—speaks disparagingly of the metric system.

Of course, you will recognize that Dr. Stratton is a manufacturer and entitled to cast a slur upon anyone who is not. More to the point, however, this is Dr. Statton's way of brushing aside Mr. Dale's overwhelming facts showing the utter failure of the metric system in the textile industries of metric Europe and the infinite harm that has come from the attempt to introduce it. Again in the same report Dr. Stratton says:

Some well-meaning men have urged that English measures were working well enough and that a change would be all but impossible. Yet the very firms concerned are using the metric system for their own profit. No more can be asked.

Again you see how easily be brushes aside our whole case. Mr. Sharpe is a "well-meaning man" who has "urged

that a change would be all but impossible"; but he makes metric micrometers, gages, reamers and other tools for sale abroad, and he has thus shown that his difficulties are imaginary.

Again we have from Dr. Stratton in a recent hearing before the House Committee on Coinage, Weights and Measures:

The objection to it came largely through ignorance, and I will use that word qualifiedly—I mean people who are not familiar with the system. They would be very intelligent otherwise. When I came to Washington, I remember a series of very interesting hearings in this roon on the metric system.

"The objection to it came largely through ignorance." Here you have again the insufferable Phariseeism of these people. You are "ignorant" of your own business, but Dr. Stratton is all-wise. He knows your business and all others. And the man who says this does not know factory measurements. He knows nothing of what this change means.

But Dr. Stratton "remembers a series of very interesting hearings." That is the net result of your tremendous efforts in filling that committee room for two years when you overwhelmed the committee on Coinage, Weights and Measures and destroyed Dr. Stratton's case. Evasion, concealment and downright misrepresentation, with the slogan "Claim everything," make up the metric case.

The situation is comic or tragic, according to the viewpoint. Another adverse fundamental condition that we have to fight arises from the misleading comparisons which are constantly made with our decimal currency. Did you ever make a table of our coins? I presume not, and so I will give it, as follows:

5 cents make a nickel
2 nickels make a dime
2½ dimes make a quarter
2 quarters make a half-dollar
2 half-dollars make a dollar.

In this table every denomination that can be divided by two without a remainder is so divided. As it appears on the ledger or invoice, our currency is purely decimal; but when we make coins for the actual measurement of values, we get as far from decimals as we can. There is no better illustration of the limitations and inadequacy of decimals. Because we write it decimally, our currency is constantly made to serve as an argument for the metric system; and this argument is as plausible and as hollow as all the rest.

Finally, we have to recognize that the national Bureau of Standards, with an appropriation of $800,000 a year, is a giant engine for the promulgation of the metric system.

Two other resolutions were also passed, one dealing with time study and premiums and the other on coöperation for national defence. The first of these resolutions reads:

Whereas, There is now pending in Congress, House Bill 8665, known as the Tavenner Bill, to regulate the method of directing the work of the Government employees, the object of which is to prohibit at the Government arsenals what are known as time studies and premium payments, and

Whereas, This association fully agrees with the facts and request set forth by the Hon. Newton D. Baker, Secretary of War, in a letter to the Speaker of the House of Representatives under date of Apr. 20, 1916, therefore be it

Resolved, That this association notify the Committee on Military Affairs of its disapproval of said H. R. Bill 8665 and that our members do all in their power to help the defeat of this bill and to strengthen the hands of the Secretary of War.

The second resolution follows:

Whereas, The Naval Consulting Board composed of foremost inventors and engineers has been created to assist the Government in the making of plans for national defense,

Whereas, The coöperation of the nation's industries in achieving adequate defense undertakings is of the utmost importance to the country contemplating the vast supplies needed in time of national peril, and

Whereas, The several engineering societies are coöperating to furnish an inventory of industries which may be available as sources of supply in time of the nation's need, committees of engineering having been appointed in various states to direct the making of such an inventory,

Be It Therefore Resolved, The National Metal Trades Association in convention assembled heartily endorses the making of an inventory of industries as a most important feature in industrial preparedness, which not only should result in a better knowledge of sources of supply for the Government, but also will assist our own members to a better realization of the possibilities of their own manufacturing plants, and be it

Resolved, The several members of the association are urged to heartily coöperate with their own state committees in furnishing desired information which will make the industrial inventory possible.

The new officers are: W. H. Van Dervoort, president (Root & Van Dervoort Engineering Co.); George Mesta, first vice-president (Mesta Machine Co.); J. W. Higgins, second vice-president (Worcester Pressed Steel Co.); F. C. Caldwell, treasurer (H. W. Caldwell & Sons Co.); John D. Hibbard, commissioner; Homer D. Sayre, secretary. The councilors for 1917 remain as before, except that Herbert H. Rice, the retiring president, replaces J. W. Higgins, the new second vice-president. The new councilors for two years are Theodore O. Vilter, Milwaukee, Wis.; B. F. Tobin, Detroit, Mich.; H. N. Covell, New York; Murray Shipley, Cincinnati, Ohio; R. H. Jeffrey, Columbus, Ohio; and H. B. Kennedy, New Haven, Conn.

PERSONALS

James E. Mills, formerly connected with Gilbert & Barker, has become sales manager for the Bellevue Industrial Furnace Co., Detroit, Mich.

J. J. de Boxes has severed his connection with the Century Steel Co. in order to form the Apex Steel Corporation, 50 Church St., New York, N. Y., of which he will be president.

Paul Kendig, vice-president of the Seneca Falls Manufacturing Co., Seneca Falls, N. Y., has resigned. Mr. Kendig will devote his entire time to other interests with which he has been connected.

James P. Farrell, resigned his position as chief engineer of the Garrison Machine Works, Dayton, Ohio, to become associated with the Dayton Stamping and Tool Co., Dayton, Ohio, in a similar capacity.

W. B. Gardiner, until recently production superintendent of the Modern Tool Co., Erie, Penn., has joined the Remington Arms plant in Bridgeport where he will act in the capacity of chief inspector of the factory.

W. L. Schellenbach, formerly chief engineer of the Lodge & Shipley Machine Tool Co., Cincinnati, Ohio, has established an office in the First National Bank Building, Cincinnati, where he will practice consulting engineering, especially that covering machine design.

Henry Cave, president of the Cave Welding and Manufacturing Co., which has acted as the New England agency of the Davis-Bournonville Co. for many years, has become directly connected with the latter company for which he will be in charge of the research department.

BUSINESS ITEMS

The Bellevue Industrial Furnace Company, Detroit, Michigan, has acquired the Krentler Bros. buildings at 1315 Bellevue Avenue. This gives them an additional floor space of 6,000 sq.ft.

M. A. Palmer Co., 469 Atlantic Ave., Boston, Mass., has just moved into larger quarters at this address, where they will handle tool steel, forgings and die blocks, crucible and openhearth steels.

The International Machine Tool Company, Indianapolis, Ind., has contracteed for the erection of an addition to their plant which will provide additional 15,000 sq.ft. in which new equipment will be installed.

TRADE CATALOGS

C. J. Jackson, Easton, Penn. Circular. "Peerless" 1916 all steel stfety shaft hanger. Illustrated.

Henry Disston & Sons, Inc., Philadelphia, Penn. Pamphlet. "Why a Saw Cuts." Illustrated, 12 pp., 6x9 in.

Canton Foundry and Machine Co., Canton, Ohio. Catalog. Portable floor crane and hoist. Illustrated, 4x7½ in.

Link-Belt Co., Chicago, Ill. Booklet No. 267. "Moving Material Indian File." Illustrated, 24 pp., 3½x6½ in.

C & C Electric & Mfg. Co., Garwood, N. J. Bulletin No. 102-X. Type "IB" motors with commutating poles. Illustrated, 8 pp., 8x10½ in.

Prices--Materials and Supplies

IRON AND STEEL

Pig Iron—Quotations were current as follows at the points and dates indicated:

	Apr. 28, 1916	One Month Ago	One Year Ago
No. 2 Southern Foundry, Birmingham	$15.00	$15.00	$9.50
No. 2 X Northern Foundry, New York	20.75	20.50	14.25
No. 2 Northern Foundry, Chicago	19.00	19.00	13.00

2	11.10	7.40	17.58	11.29
2½	18.72	12.29	30.13	18.43
3	24.48	16.07	39.40	24.10
4	34.88	22.89	56.14	34.34
5	47.36	31.08	76.22	46.62
6	62.44	40.32	98.88	60.48

From New York stock the following discounts hold:

	Black	Galvanized
3½ to 6 in. steel lap welded	61%	36%
¾ to 3 in. steel butt welded	64%	42%

Malleable fittings, Class B and C, from New York stock sell at 30 and 5% from list price. Cast iron, standard sizes, 54%.

Bar Iron—Prices are as follows in cents per pound at the places named:

	Apr. 28, 1916	One Month Ago
Pittsburgh, mill	2.50	2.45
Warehouse, New York	3.15	3.10
Warehouse, Cleveland	3.25	3.25
Warehouse, Chicago	3.10	3.10

Bar Steel sells at $3.25 per 100 lb. from warehouse, New York.

Cold Drawn Steel Shafting—From warehouse to consumers requiring fair-size lots, the following quotations hold:

	Apr. 28, 1916	One Month Ago
New York	List price plus 20%	List price plus 10%
Cleveland	List price plus 20%	List price plus 20%
Chicago	List price plus 10%	List price

Swedish (Norway) Iron—This material per 100 lb. sells as follows f.o.b. places named:

New York Today	New York One Year Ago		
$5.50	$3.75@4.00	Cleveland... $5.80	Chicago... $4.25

In coils an advance of 50c. is usually charged.

High Speed Tool Steel containing from 10 to 18% tungsten sells as follows per pound in New York:

Billets ....$2.35   Bars $3.00

METALS

Miscellaneous Metals—The present quotations in cents per pound, with a comparison of practically a month and year ago, are as follows:

	New York		
	Apr. 28, 1916	One Month Ago	One Year Ago
Copper, electrolytic (carload lots)	*30.50	27.00	19.00
Tin	50.00	49.00	41.00

Flats	32.50	33.00	33.50	36.00	37.00

Flats not rolled wider than 6 in. or less than ⅛ in. thick.

Hexagon bars 2c. per lb. over corresponding size of round rods.

For cutting to any specified length not shorter than 1 ft. add 1c. per lb.

The scrap allowance is 18c. per lb. delivered at works.

Antimony—Chinese and Japanese brands are quoted in cents per pound for spot delivery, duty paid:

	Apr. 28, 1916	One Month Ago
New York	39.00	45.00
Cleveland	50.00	50.00
Chicago	45.00	44.75

Copper Bars from warehouse sell as follows in cents per pound:

	Apr. 28, 1916	One Month Ago
New York	42.00	40.00
Cleveland	31.50	39.00
Chicago	....	38.00

Babbitt Metal—Quotations are as follows in cents per pound from warehouse at the places named:

	New York	Cleveland	Chicago
Best grade	60.00@65.00	58.00	58.00@60.00
Commercial	30.00@35.00	22.00	25.00@30.00

Copper Sheets—In New York hot rolled 16 oz. (large lots) base per lb. is 36.50c.; cold rolled 14 oz. and heavier add 1c.; polished takes 1c. per sq.ft. extra for 20-in. widths and under; over 20 in., 2c.

SHOP SUPPLIES

Nuts—From warehouses at the places named, on fair sized orders the following amount is deducted from list:

	New York Apr. 28, 1916	New York One Month Ago	Cleveland Apr. 28, 1916	Cleveland One Month Ago	Chicago Apr. 28, 1916	Chicago One Month Ago
Hot pressed square	$2.50	$3.00	$3.25	$3.75	$3.25	$3.70
Hot pressed hexagon	2.50	3.20	3.50	3.75	3.25	3.80

The Chalmers Motor Co. contemplates the construction of an addition to its plant at Saskatoon, Sask. Estimated cost, $500,000.

The Saskatchewan Bridge and Iron Works, Medicine Hat, Alta., is building a plant at Medicine Hat.

An addition will be built to the plant of the Begg Motor Co., 1062 Georgia St., W., Vancouver, B. C. Estimated cost, $15,000.

GENERAL MANUFACTURING

NEW ENGLAND STATES

Fire, Apr. 21, destroyed the factories of the Canonchet Line and Twine Co. and the Union Line and Twine Co. at Canonchet, R. I. Loss, $50,000.

MIDDLE ATLANTIC STATES

The Glove Woven Belting Co., Buffalo, N. Y., plans to construct a 1-story factory at 1420 Elmwood Ave. Estimated cost, $10,000.

The Clayville Knitting Co., Clayville, N. Y., has awarded the contract for the enlargement of its plant. Estimated cost, $200,000. Noted Apr. 20.

The contract has been awarded for the construction of a new plant on Plum Point Lane, Newark, N. J., for John Campbell & Co., New York, N. Y., manufacturer of chemicals. Estimated cost, $35,000.

The Radel Leather Manufacturing Co. plans to construct an addition to its plant on Hamburg Place Rd., Newark, N. J.

Plans are being prepared by Moses, Pope & Messer, Arch., 366 5th Ave., New York, N. Y., for a plant at Newark, N. J., for the Stillwell Chemical Co., 2 Rector St., New York.

The contract has been awarded for the construction of a 4-story silk mill on Straight St., Paterson, N. J., for Dunlop Bros., 254 4th Ave., New York, N. Y. Estimated cost, $110,000. Noted Mar. 16.

The contract has been awarded for the construction of a 3-story factory on Union Ave., Paterson, N. J., for Harris Bros. Silk Co., 25 Manchester Ave., Paterson. Estimated cost, $20,000. Noted Apr. 6.

The Folding Partition Co., 200 Broadway, New York, N. Y., has acquired a site on Market St., Perth Amboy, N. J., and will establish a plant for the manufacture of its patented section-fold partitions.

The contract has been awarded for an addition to the plant of the Star Porcelain Co., Muirheid Ave., Trenton, N. J. Noted Jan. 13.

Plans are being prepared by Moses, Pope & Messer, Arch., 866 5th Ave., New York, N. Y., for an addition to the plant of the American Analine Chemical Co., West Nutley, N. J. (Newark post office). Estimated cost, $25,000.

The contract has been awarded for the construction of a chemical factory for the General Manufacturing Co., 30th and Market St., Philadelphia, Penn. Estimated cost, $10,000.

The contract has been awarded for the construction of a box factory for George W. Kugler Sons Co., 921 Market St., Philadelphia, Penn.

The contract has been awarded for the construction of a 2-story factory at 37th and Tasker St., Philadelphia, Penn., for the Nitrogenous Chemical Manufacturing Co. Noted Apr. 20.

The Security Silk Co., Morris Run, Penn., has awarded the contract for the construction of a silk mill. Noted Mar. 23.

Fire recently destroyed the Heidelberg plant of the Aetna Chemical Co., near Pittsburgh, Penn. Loss, $50,000.

The Standard Box Co., Reading, Penn., has awarded the contract for the construction of a box factory.

The Rich Woolen Mills, Woolrich, Penn., is having plans prepared for an addition to its plant.

SOUTHERN STATES

The Richmond Leather Co., 22d and Carey St., Richmond, Va., plans to construct a 2-story factory. Estimated cost, $16,200.

The Ideal Paper Box Co., Parkersburg, W. Va., plans to construct a plant.

The J and D Tire and Rubber Co., Charlotte, N. C., plans to construct a 2-story factory. Herbert O. Smith, Indianapolis, Ind., is Pres.

C. B. Armstrong will build a mill at Gastonia, N. C., for the manufacture of cotton yarns.

The National Dye and Munitions Co., New York, N. Y., has awarded the contract for the construction of a plant at Sanford, N. C. Estimated cost, $10,000,000.

The N. P. Josey Guano Co., Scotland Neck, N. C., will rebuild its fertilizer plant recently destroyed by fire. Estimated cost, $50,000.

The Buffalo Shoals Clay Manufacturing Co., Statesville, N. C., recently incorporated, plans to construct a factory.

The Wendell Knitting Mills, Wendell, N. C., plans to enlarge its plant.

The Huntley Furniture Co., Winston-Salem, N. C., has awarded the contract for a 4-story addition to its plant. Noted Apr. 6.

The Middleton Warehouse and Compress Co. plans to construct a compress at Charleston, S. C. Charles F. Middleton is Pres.

The Titus Clay Products Co., Columbia, S. C., plans to enlarge its plant.

The Southland Knitting Mills, Macon, Ga., is building a 40x100-ft. addition to its plant.

The contract has been awarded for the construction of a compress at Savannah, Ga., for the Savannah Warehouse and Compress Co.

The contract has been awarded for the construction of a knitting mill at Attalla, Ala., for W. B. Davis, Co., Chattanooga, Tenn. Estimated cost, $10,000. Noted Apr. 13.

The Opelika Cotton Mills, Birmingham, Ala., plans to enlarge its plant.

Fire recently destroyed the cotton compress of the Sheffield Cotton Co., Sheffield, Ala. Loss, $125,000.

The Lane Cotton Mills Co., New Orleans, La., plans to construct an addition to its plant.

The Chattanooga Aseptic Cotton Co., Chattanooga, Tenn., has awarded the contract for the construction of a new plant. Noted Apr. 6.

The Davis Hosiery Mills, Chattanooga, Tenn., has awarded the contract for the construction of a factory at Bristol, Tenn.

The 638 Tire and Vulcanizing Co., Memphis, Tenn., plans to construct a service station. Estimated cost, $35,000. G. M. Shaw & Co., Memphis, Arch.

The John J. Delker Carriage Co., Henderson, Ky., is building a new plant.

The Adler Manufacturing Co., Louisville, Ky., manufacturer of pianos and organs, will build an addition to its factory. Estimated cost, $15,000.

Plans being considered by the Louisville Chemical Co., 108 South 3d St., Louisville, Ky., for the enlargement of its plant.

The East London, Ky., handle factory of the Turner, Day & Woolworth Co., Louisville, Ky., recently destroyed by fire with a loss of $3,000, will be rebuilt. L. B. Murphy, East London, is Mgr.

Plans have been prepared by D. H. Jamieson, Arch., for a new plant for the Paducah Hosiery Mills, Paducah, Ky. Noted Apr. 27.

MIDDLE WEST

The Akron Airless Tire Co. will construct a plant at Akron, Ohio. Estimated cost, $150,000.

The Icy-Hot Bottle Co., 120 West 2nd St., Cincinnati, Ohio, plans to enlarge its factory at Cincinnati.

The Sayers & Scoville Co., 2247 Colerain Ave., Cincinnati, Ohio, will rebuild its carriage factory at Cincinnati, recently destroyed by fire with a loss of $200,000.

Plans are being prepared for the construction of a cold-storage plant at Lorain, Ohio, for the Amherst Supply Co.

Plans have been prepared for the construction of a 2-story, 60x150-ft. factory on Barnhart St., Marion, Ohio, for the Marion Tire and Rubber Co. Estimated cost, $15,000. Noted Apr. 6.

The Toledo Bottle Co., recently incorporated, plans to construct a plant at Toledo, Ohio. Frank O'Neill is Pres.

Plans are being prepared for the construction of a 1- and 2-story plant at Terre Haute, Ind., for the Grasselli Chemical Co. Estimated cost, $200,000. W. T. Cashman, 980 The Arcade, Cleveland, Ohio, is Asst. Secy. Noted Apr. 13.

Plans are being prepared for the construction of a gravel washing plant at West Terre Haute, Ind., for the Vandalia R.R. Co. Estimated cost, $35,000. F. T. Hatch, Syndicate Bldg., St. Louis, Mo., Ch. Engr.

The Champion Ignition Co. has awarded the contract for the construction of an addition to its plant at Flint, Mich. Noted Apr. 13.

The Pennsylvania Salt Manufacturing Co. plans to rebuild its plant at Wyandotte, Mich., which was recently destroyed by fire with a loss of $200,000.

The Fulton Saw Works, 52nd Ave. and 22nd St., Chicago, Ill., has awarded the contract for the construction of a 1- and 2-story factory at Chicago. Noted Apr. 13.

The I. Horween & Co. will construct an addition to its plant at 1051 West Division St., Chicago, Ill. Estimated cost, $20,000.

The Inter-Lake Pulp and Paper Co. contemplates constructing a 4- or 5-story mill at Appleton, Wis. W. A. Fannon is Mgr.

Plans are being prepared by Henry Auler, Arch., for the construction of a 2-story, 66x70-ft. factory at Berlin, Wis., for the Berlin Fabric Manufacturing Co. Estimated cost, $18,000.

WEST OF THE MISSISSIPPI

The Perfection Tire and Motor Co., Ft. Madison, Iowa, will erect a new plant for the manufacture of automobile tires. Estimated cost, $300,000.

The Goodyear Tire Co., Red Wing, Minn., plans to construct a factory.

W have been informed that the Ohio Oil Co., Findlay, Ohio, does not plan to construct an oil refinery at Greybull, Wyo., as stated in our issue of Apr. 20.

The Corsicana Cotton Mills, Corsicana, Tex., has awarded the contract for a 2-story addition to its plant. Estimated cost, $100,000. Noted Mar. 23.

The Farmer's Gin Co., Gonzales, Tex., will construct a cotton gin. Estimated cost, $15,000. D. Stahl, interested.

The Texas Refining Co. will construct a cotton seed oil mill at San Antonio, Tex.

The Seguin Compress Co., Seguin, Tex., will build a cotton gin. Estimated cost, $25,000.

Fire recently destroyed the plant of the Interstate Compress Co., Hobart, Okla.

According to press reports the Kingston Cotton and Oil Co., Kingston, Okla., plans to establish a cold press mill, 3 cotton gins and a boiler plant at Kingston. C. C. Chestnut, Pres. and Mgr.

J. R. Pruett, Mannsville, Okla., plans to establish a canning plant.

The Southwestern Tire Manufacturing Co. recently incorporated, Colcord Bldg., Oklahoma, Okla., plans to construct a factory. Estimated cost, $200,000. J. L. McClelland is Pres.

H. P. Anderson and associates, Tulsa, Okla., plan to construct a cold-storage plant at Tulsa. Estimated cost, $300,000.

The Enterprise Window Glass Co., Tulsa, Okla., plans to construct a plant at Mexia, Tex., for the manufacture of window glass.

A plant for the manufacture of horse collars and harness will be equipped at Woodward, Okla., by the Woodward Manufacturing Co., recently incorporated. J. E. Milby and J. D. Gray are interested.

WESTERN STATES

Press reports state that the Union Knitting Mills Co. is constructing a mill at Logan, Utah. Estimated cost, $40,000.

The Utah Canning Co. will build an addition to its plant at 29th St. and Pacific Ave., Ogden, Utah.

The E. E. Samson & Co. plans to construct a cold storage plant at North Yakima, Wash.

The Western Meat Co. plans to construct an addition to its cold-storage plant at Fresno, Calif. Estimated cost, $7,500.

The contract has been awarded for the construction of a 1-story box factory for the American Can Co., Mills Bldg., San Francisco, Calif.

CANADA

The Skedden Brush Co., 130 King St., N., Hamilton, Ont., will construct an addition to its factory at Hamilton. Estimated cost, $5,000.

Plans have been prepared for an addition to the plant of the Perfection Tire and Motor Manufacturing Co. of Ft. Madison, Iowa, at Niagara Falls, Ont. Estimated cost, $300,000.

The Simcoe Shoe Co. will construct a factory at Simcoe, Ont. Estimated cost, $15,000.

Bids are being received for the construction of a factory at Toronto, Ont., for A. R. Clarke & Co., 633 Eastern Ave., manufacturer of leather goods.

The York Knitting Mills Co., 993 Queen St., W., Toronto, Ont., is building an addition to its factory at Queen and Shaw St. Estimated cost, $70,000. Noted Apr. 6.

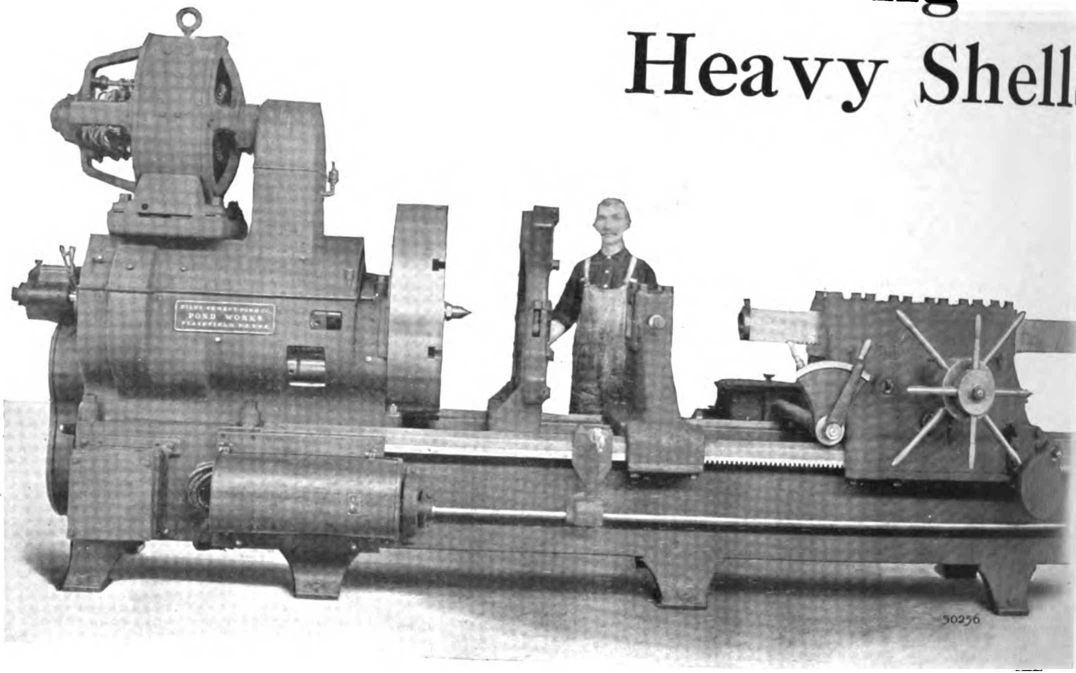
Prompt Delivery

Lathes For Boring

Heavy Shells



36-In. Heavy Lathe with boring tailstock.

All Steel Gears

Lathes are equipped throughout with steel gears and are driven by 20-hp. motors. Rear end of spindle is provided with a special thrust bearing of heavy construction to take the end thrust due to boring large holes.

Boring Tailstock

The boring ram is forged steel 6-in. square, and has a very long bearing in the tailstock. The ram feed is driven from the feed shaft, at the rear of the bed, through worm and worm wheel giving a smooth motion for boring. By means of two levers four feeds can be obtained without changing any gears. These levers are attached to the tail stock and hence are always in a convenient position.

Supports for Work and Boring Ram

A steady rest is provided to support the shell or other work. There is also furnished a special rest to support the end of the boring ram. This rest moves along the bed with the ram as it feeds.

Specifications, Delivery, Prices, etc., Promptly Furnished on Request.

What the Engineers are Doing

THIRTY thousand American engineers are making a card index survey of American industry so that it may be prepared for its vital part in defending the country, if need comes. The past eighteen months have taught us here in America what lack of industrial preparedness has meant to some of the countries now at war. These nations had the ships and they had the men; but when the hour struck, their factories were not able to furnish the colors with arms and shells and powder. Their factories were not prepared. And our factories are not prepared.

But it is not enough to draw a moral. In the United States five great Engineering Societies—Civil, Mining, Mechanical, Electrical and Chemical—have pledged their services to the Government of the United States, and are already working hand in hand with the Government to prepare industry for the national defense. They receive no pay and will accept no pay. All they seek is opportunity to serve their country, that she may have her industries mobilized for defense.

All elements of the nation's life—the manufacturers, the business men, and the workingmen—should support this patriotic and democratic work of the engineers, and assist them cheerfully when asked. *There can be no better national insurance against war.*

The Associated Advertising Clubs of the World, representing all advertising interests, have offered their free and hearty service to the President of the United States, in close co-operation with these five Engineering Societies, to the end that the country may know what the engineers are doing. The President has accepted the offer. The engineers have welcomed the co-operation.

This advertisement, published without cost to the United States, is the first in a nation-wide series to call the country to the duty of co-operating promptly and fully with the engineers.

Building Single-Purpose Lathes in a Single-Purpose Shop

By Ethan Viall

SYNOPSIS—The building and machine-construction methods outlined in this article constitute an unusually remarkable series of engineering achievements. The machines were made to produce shells and the plant to produce machines. A notable feature is that the building is long and narrow, the work moving across it and not lengthwise, as usual. The machines are so designed as to eliminate all the machine work possible, there being absolutely none on the main-frame casting. The comparatively few machined parts are made in quantities, all interchangeable, and then assembled with a speed that is almost incredible.

The first great demand for shell machinery and tools was for the smaller sizes. Established makers eliminated the manufacture of all machines except those which were in immediate demand and could be most easily produced. Special or single-purpose machines were designed as rapidly as possible or were improvised by leaving off the nonessentials from regular models. The average shop, however, was not fitted to produce machinery capable of machining the larger sizes of shells. Probably less than a half-dozen shops in this country had sufficient room and production machines for large work. As a consequence practically everyone concerned concentrated on machines for producing shells under 4.5 in. The demand for larger shells steadily increased, but proper machinery could not be obtained. This condition led to the formation of the Amalgamated Machinery Corporation, of Chicago.

Ignoring the overcrowded small-shell field, its efforts were directed entirely to the construction of machines for making the largest sizes of shrapnel and high-explosive shells. Shells demand accuracy. The demand for large shells was urgent. It naturally follows that machines to do the work required must be made right and be made quickly. That these conditions were successfully met will be apparent from this article.

It must be remembered, however, that market conditions were extraordinary. Otherwise, it is extremely doubtful whether anything so radically different from existing types would have been given anything like a fair trial. The fact that shell-making plants having huge batteries of these machines are constantly reordering more is proof enough of their accuracy, durability and success for the purpose for which they were designed. The machines themselves have previously been described in these columns, so this article will be mainly confined to a description of the construction, or assembling and handling, methods. However, a brief review of the main features will be given in order that the reader may follow clearly.

Someone has said that the history of machine design always shows three stages of progression—first, crude directness; second, unnecessary complexity; and third, finished simplicity. Maudsley's first lathes are said to have had triangular bars for ways, the design of course being adopted for the sake of expediency. Planers were made a number of years later, and the triangular bar in subsequent lathes was cast directly on the bed, as it could be machined to a finish where the first bars had to be hammered, chipped and filed. Started in this manner, tradition and the dislike of change have continued the triangular form of ways to this day. Any radical departure from such accepted practice would have been a losing venture at a time unfavorable to its introduction, though it is extremely probable that if Maudsley could have obtained stiff, hard, accurate bars of round stock,

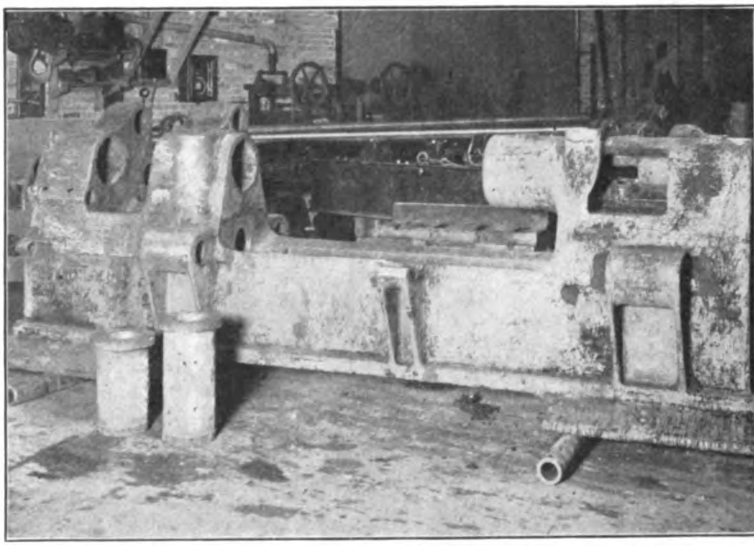

FIG. 1. FRAME CASTING AS IT APPEARS AFTER COMING FROM THE FOUNDRY

FIG. 2. METHOD OF PUTTING IN THE BUSHINGS

he would have used them in preference to the triangular ones.

In making the Amalgamated ammunition machinery the designers broke entirely away from traditional practice, unhampered by the necessity of making something adapted to manufacture with any existing equipment in any existing shop. The essentials insisted upon were that the machines should be strong, rigid, durable, capable of operation with ordinary labor, very accurate where accuracy is necessary, conveniently handled, capable of machining shells with as little tool expense and as great exactness as any other machines and with as high a rate of production. In addition, the design was to permit the use of such materials of construction as were readily obtainable in quantities sufficient for all reasonable requirements and to provide for deliveries in time and quantity that had been unheard of previously. One of the claims for the type of machine produced is: "A machine . . . having a plurality of bearing bushings, castings having recesses in which said bushings are mounted, the bushings being held in said recesses by fusible metal surrounding the bushings, and certain of the bushings forming bearings for the working parts of the machine." Such construction makes possible the use of round-steel guide ways in a manner that insures perfect alignment and at the same time requires the least possible time in the factory and the least floor space for assembly.

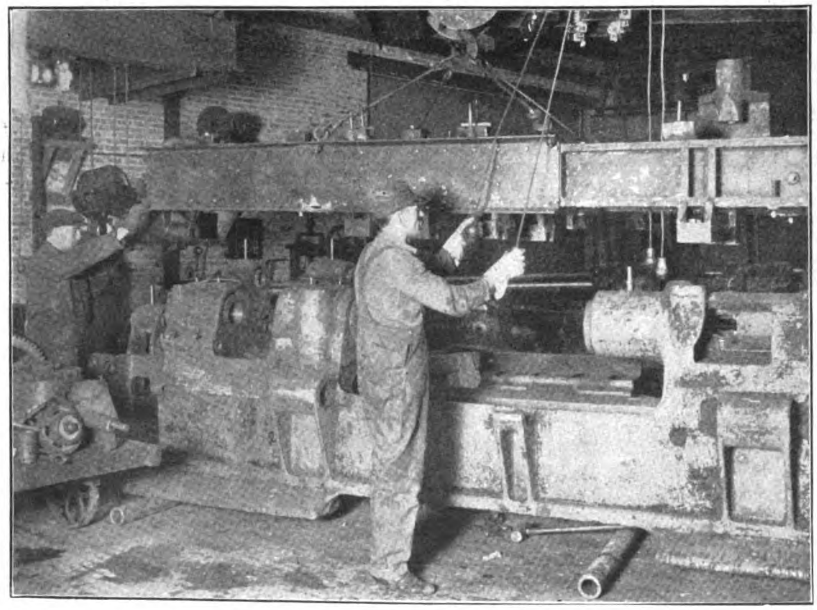

FIG. 3. LOWERING THE JIG INTO POSITION

The first machine designed along these lines was a turning lathe, with headstocks and tailstocks cast integral with the bed. It has a swing over the ways of 27½ in. and over the carriage of 13 in. It covers a floor space 4x17 ft. and weighs about 18,000 lb. This machine was made complete and tested out in 28 days from the time the drawings were started! I recently saw this same machine take a demonstrating cut on a regular 9.2-in. steel shell at 28 r.p.m., producing a chip ⅞ in. wide and ⅛ in. thick. Not the least sign of chatter or stalling developed, though no tools will stand up under such a terrific strain for any length of time. Such a cut, of course, has no place in shell-making practice, but shows conclusively the great power of the machine.

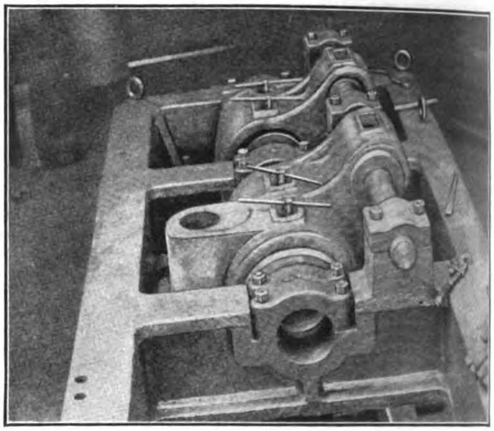

FIG. 4. VIEW OF HEADSTOCK FROM ABOVE WITH JIG IN POSITION

Though a number of sizes and models of machines are made for all kinds of shell work from 4.5 in. up, the general principle of construction is the same in all. Absolutely no machine work of any kind is done on the main frames, which go direct from the foundry to the assembling floor. For this reason examples of the assembling steps for one model will be sufficient to give a good idea of how all are constructed, though a few of another model will be used to illustrate something special. The frame of a No. 21 machine, just as it comes from the foundry, is shown in Fig. 1. On the floor in front are two bearing bushings. This type of babbitt-lined cast-iron bushing is used for all rotating shafts. The bushings are cored with dovetail grooves on the inside to anchor the babbitt, and the babbitting work is done by the National Lead Co. Every precaution is taken to obtain the best results. It is well known that each remelting of a babbitt mixture injures it, so these linings are poured direct from the original mix, which contains 85 per cent. tin, 7½ per cent. copper and 7½ per cent. antimony. About 140 lb. of babbitt is used for each machine of this size. After pouring, the bearings are bored to a uniform size and then compressed by means of a blunt rotating-pin tool and then finish-bored and fitted to the spindles. From 0.001 to 0.0015 in. is allowed between the spindle and the bearings for the oil film. The babbitted bearings include the main-spindle bearings, those for the back-gear shaft and the pulley. All others on the machine are of fine, close-

grained cast iron, no babbitt being used in any place for sliding bearings.

As the live spindle is 5$\frac{15}{16}$ in. in diameter and runs in bearings 20½ and 16 in. long, there is something like 6 per cent. more projected area of bearing than there is on the four bearings under one end of a standard 80,000-lb. capacity freight-car total!

In Fig. 2 a machine is shown with all the babbitt-lined bushings in place. The workman is just pushing a cast-iron bushing into the cored hole in the front end of the tailstock.

The next operation is to lower a huge jig down on the frame, for the purpose of correctly locating the various bushings and guide rods. This jig is illustrated in Fig. 3. It weighs in the neighborhood of 4 tons, being so made to secure rigidity and insure perfect alignment of the mandrels.

Fig. 4 is a view of the headstock and end of the jig as seen from the top after a mandrel has been thrust through the back-gear bushings, but before the spindle mandrel has been pushed through. Small cross-handled screws will be observed in the oil pockets of the spindle bearings. Each babbitted bushing is drilled and tapped with a ⅞ tap. In each tapped hole a screw is placed, as shown. After the locating mandrel has been run through the bushings, these screws are tightened so as to draw the bearing firmly against the bottom of the mandrel. This is to forestall any floating tendency on the part of the bushings when the type metal that is used to hold the bushings is poured in. The natural conclusion would be that all would float alike anyway; but in practice this is not true, as any slight obstruction would interfere. If one floated the 0.001 in. or so allowed while another did not, the alignment would be seriously affected. Arranged in this way, the alignment is correct in any case.

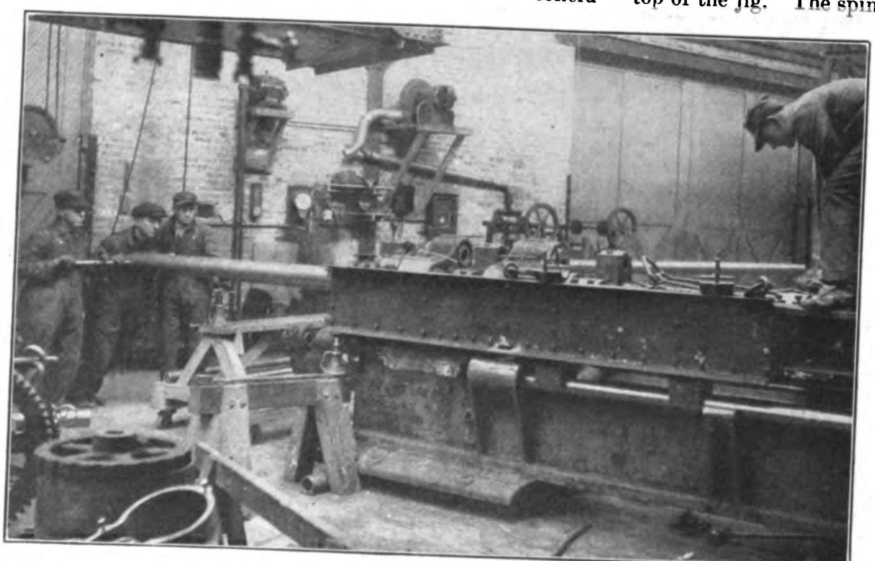

FIG. 5. PUSHING IN MAIN-SPINDLE MANDREL

Previous to any of the mandrels being run through, the jig is brought so that the various guide bushings are approximately central with the cored holes in the frame. This is done by means of screw-jacks suitably placed or by shoving one way or the other. The mandrel for the main spindle is shown being pushed into place in Fig. 5.

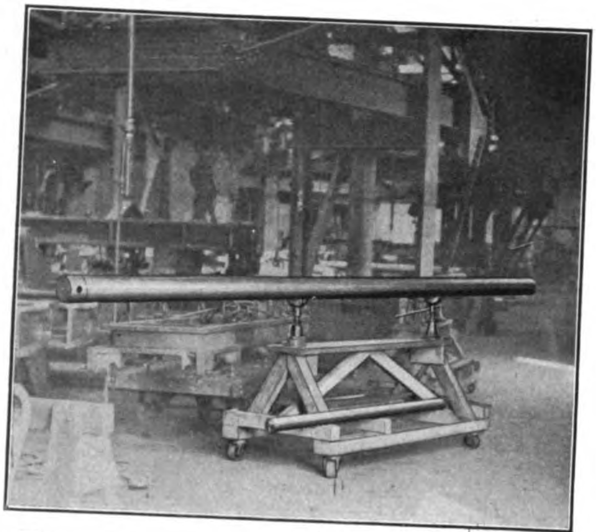

FIG. 6. TRUCK FOR HOLDING ALIGNING MANDRELS

The three men shove while the man on top juggles the bushings in the cored holes. The mandrel itself is of course guided by the bushings of the jig. One of the carriage guide rods is also seen in place in the frame. There is another similar rod at the back, and they correspond to the usual lathe ways. They are held to the jig blocks above by means of caps shown lying loose on top of the jig. The spindle mandrel is 16 ft. long, weighs 1,600 lb. and is supported in seven fully encircling bearings, set in the framework of the heavy, rigid jig. With this construction there can be no question of the perfect alignment of the bearings, since the mandrel is twisted out by hand after the type metal is poured around the bearing bushings. The slightest bind or distortion would make the removal of the mandrel extremely difficult, if not impossible. It must of course be remembered that the frames have had no machine work done on them. In consequence no scale has been removed, affecting the strains in the castings, so that the seasoning changes are far less than usual. When not in use, the various mandrels are carried on special trucks of the type illustrated in Fig. 6. The main-spindle mandrel is set on lead-padded jacks; and when it is to be used, the truck is run to the jig and the jacks run up or down until the mandrel is exactly in line with the guide bushings in the jig. It may then be pushed in as previously shown.

An end view of a No. 23 machine, with a jig and all the mandrels in place, is given in Fig. 7. The opposite end of this same machine previous to the setting on of the jig is shown in Fig. 8. Here a boring-bar carriage is seen, with the guide rods or ways in place. Bronze

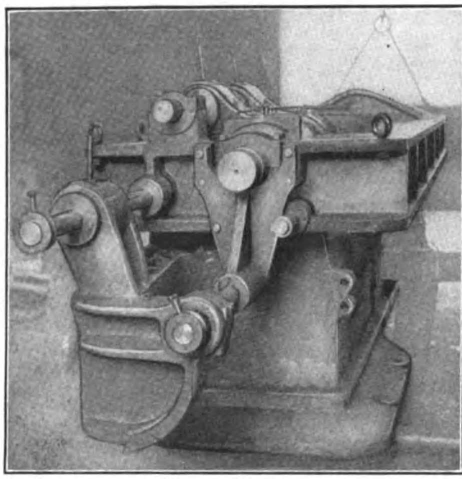

FIG. 7. END VIEW OF MANDRELS

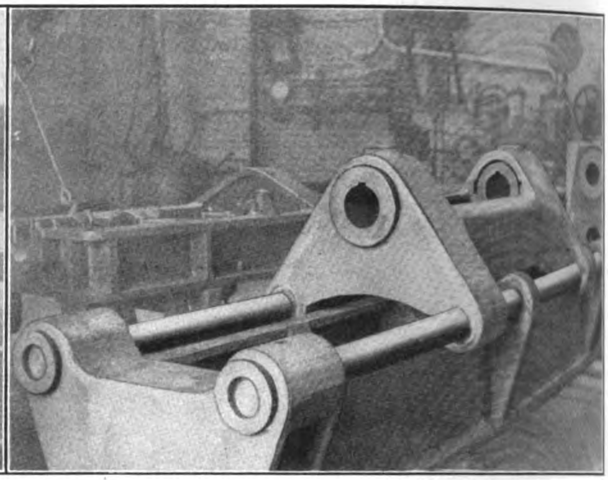

FIG. 8. BORING-BAR CARRIAGE IN PLACE

bushings are shown in the cored holes on the end of the machine bed. They are used to guide the rods through without bruising or marring them, and similar ones are used in all cases where these rods are inserted. The bushings are of course removed after they have fulfilled their mission and are laid aside for use on the next frame.

After a jig has been correctly placed, the mandrels all pushed in and the bushings located right, the various openings are luted with clay, and type metal is poured in around the bushings, setting them solidly into the cored holes of the frame. The process of pouring is shown in Fig. 9. While the men handle the ladle, another stands close with a large wad of clay ready to stop up any runs that might unexpectedly develop. Light steel ladles are used, which may be manipulated with or without a crane. This illustration also plainly shows how the guide rods or ways are held to the jig by means of caps, as previously mentioned. The clay luting may be noticed in various places. The luting clay is handled in an unusual manner. As a rule, a man simply takes a wad and rolls it up in his hands and presses it around the opening. This takes considerably more time than necessary, so here the clay is furnished the workmen in strips 1 in. square and 30 in. long. These strips are brought to the machine, laid on boards and covered with damp sheets of felt, two layers being placed on a small truck, as in Fig. 13. The advantage of this method will be seen at once by any practical man. The clay strips are made in a special power-driven machine, Fig. 15. Not only are the strips convenient to handle, but the mixture is uniform. The machine will run out two strips at a time.

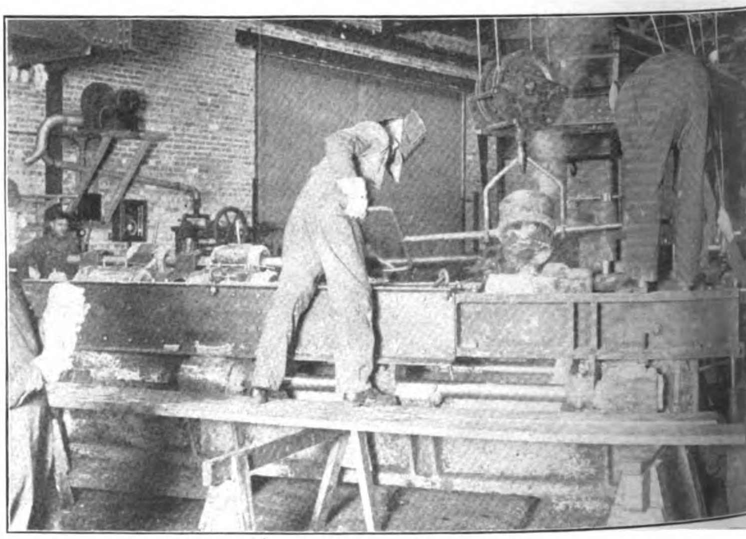

FIG. 9. POURING THE TYPE METAL AROUND THE BUSHINGS

Masks are worn by the men pouring the metal. Two of these masks are shown in Fig. 14. The face is covered with fine screen, and the neck is protected by a leather flap attached to the lower part of the mask. The ones shown were made especially to order.

About 960 lb. of type metal is used for each machine. It contains 14 per cent. of antimony, which is 1 per cent. more than the eutectic alloy of antimony and lead, the object being to allow for any loss in melting. Great care is taken in melting and bringing this special mixture to just the right temperature for pouring. A large amount of experimenting was done before any machines were built; and while the metal formula may be varied considerably, its treatment, temperature of pouring and the time of cooling are of the utmost importance. It is sufficient to say that the pouring temperature is so critical that a range of only 30 deg. F. is permitted; above that point shrinkage takes place, while below it the expansion would be great enough to result in cracking the casting retaining it.

At first thought the construction of a machine in this way would seem to be cheaper than by the time-honored designs, but a moment's consideration will disclose the error. The expense of the metal is more than enough to pay for any boring, planing and scraping that could be done on a machine of this class. The real gain is not in money, but in time and quantity of production, which could be obtained in no other way. Another thing may be mentioned here, and that is that the use of round stock is also much more expensive than it looks at first. Only 50-point carbon steel is used. It is machined and ground to size by the Cumberland Steel Co., which in addition to the regular price of the steel receives 1½c. per pound additional, which is divided into ½c. for working the high-carbon steel: ½c. for accuracy and ½c. for special inspection. The frame, with the various mandrels and the jig removed, is illustrated in Fig. 10. This view plainly shows bearing bushings in place and also the two carriage guides or ways. It will be seen that these are supported in the middle by a bracket, to eliminate all chance of springing. The tail spindle and operating mechanism are still to be put in place. The mechanism is so arranged that the holding brackets are attached to the tailstock by means of extensions or tongues, which are set down into cored holes in the casting in such a way that type metal may be flowed around to anchor them securely. The tail spindle itself moves in the cast-iron bushings, which were aligned by the bar in the big jig previously mentioned.

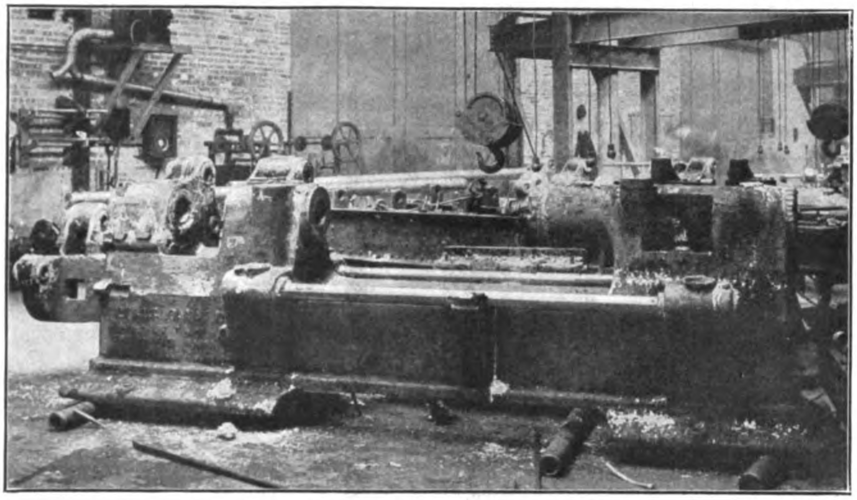

FIG. 10. FRAME WITH BUSHINGS AND GUIDE RODS IN PLACE

Fig. 11 shows the tailstock mechanism in place and the big gear being worked into position as the spindle is pushed through. This part of the assembling differs but little from that ordinarily done, except that everything is arranged for speed. Where heavy shafts or other parts are to be handled either by hand or by crane, special gripping tongs faced with leather are used. A number of these may be seen lying on a truck in Fig. 16.

The heavy flanged collar used as a faceplate is shrunk on the spindle nose. A shrinkage allowance of from 0.008 to 0.010 in. is made. A faceplate just being swung into position to be placed on the spindle nose is shown in Fig. 12. As soon as it is set in place it is cooled by water from the hose at the left. This water is caught in the tank and drains off through the hose at the right. These faceplates, finished, weigh about 220 lb. The holes in them for bolting purposes are cored in. After the faceplate has been shrunk on, it may be faced off.

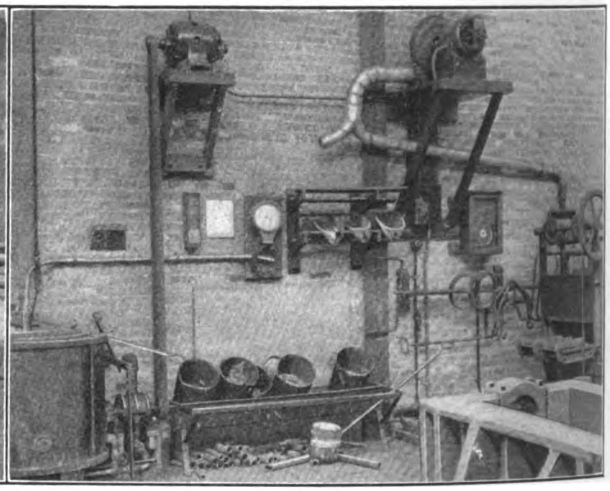

FIG. 17. ONE OF THE FURNACE SETS

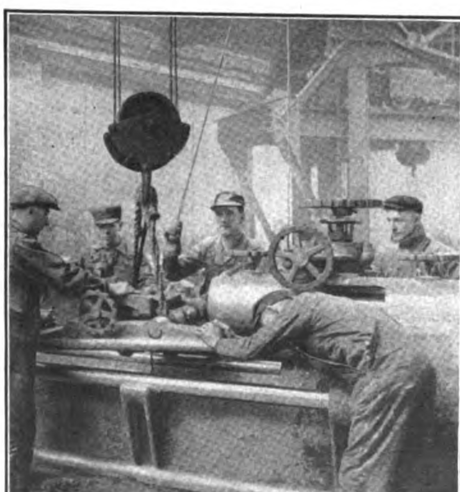

FIG. 18. LOWERING CARRIAGE ON WAYS

FIG. 19. RUNNING A TEST ON FINISHED LATHE

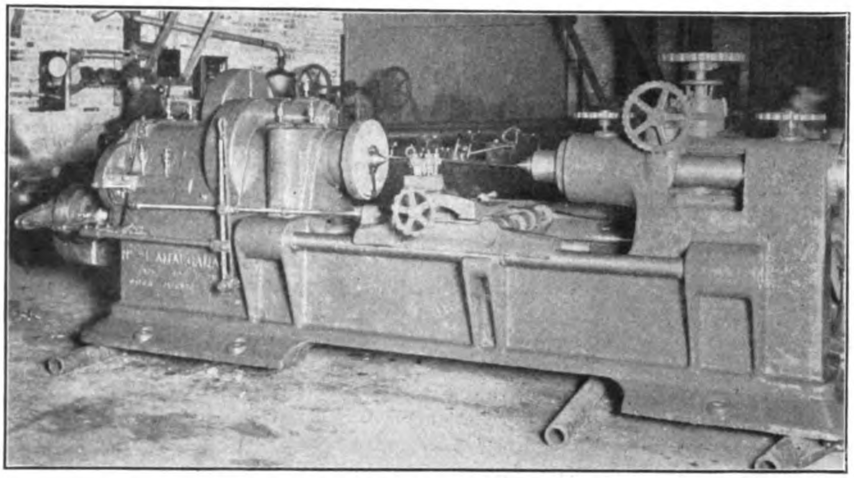

FIG. 20. COMPLETED MACHINE ALL READY TO PAINT

The shop is supplied with a number of heating sets like the one in Fig. 17. The furnace at the right heats the faceplates just described. Two little wheeled trucks may be seen just in front of the door. The faceplates are placed on these trucks and wheeled inside the furnace to heat. The weight of the faceplates makes something of this kind necessary. On the wall, next to this furnace, is shown a Bristol recording pyrometer. Farther to the left is a mask rack, at the left of which is a Bristol recording thermometer connected to the type-metal melting furnace at the extreme left. Just below the thermometer is a gas-heated rack for the metal ladles. The furnace at the left is a Stewart Special, made by

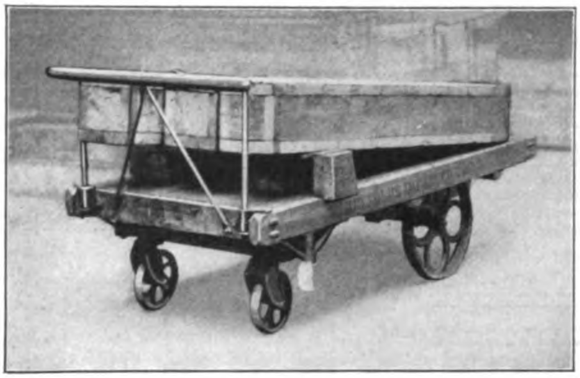

FIG. 21. BOXED SPINDLES AND SHAFTS

the Chicago Flexible Shaft Co. and capable of melting a ton of type metal an hour. The heating furnace was made by the National Machine Works, Chicago. Care must be taken to obtain the exact pouring heat of the type metal used. Hence, one man makes a specialty of this operation.

Fig. 18 illustrates a machine practically completed, with the carriage being lowered to the ways. Fig. 19 shows a running test being made with a portable apparatus. The motor used is a 3-hp. Triumph running at 1,300 r.p.m. Other tests determine the accuracy of the various parts and alignments wherever necessary. Fig. 20 shows a machine all complete, ready to be painted. The paint used is a special Sherwin-Williams mixture that will dry in an hour, and the machine may be wrapped in waterproof muslin webbed paper immediately after painting and greasing for shipment.

One of the very unusual guarantees of the company is to finish 5 per cent. of any order per day, no matter how large the order. It follows that some unusual production methods must be followed, aside from the assembling of the machines as shown. The shop is divided into units, each practically complete in itself, for the assembling of a single machine at a time. Four men constitute an assembling gang. The record for assembling a No. 21 machine is about 7½ hr. complete. A fair average seems to be 9 hr. Gears, bushings, shafts, screws and all castings are made under contract, and very little but actual assembling is done in the main shop. Except for a small room for the shafts, gears and the like, almost no storage facilities are provided. The shafts used are sent in se-

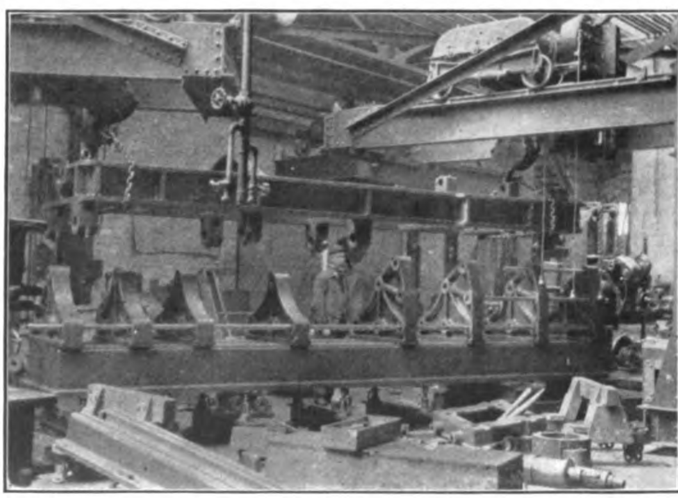

FIG. 22. VIEW OF JIG AND MASTER JIG

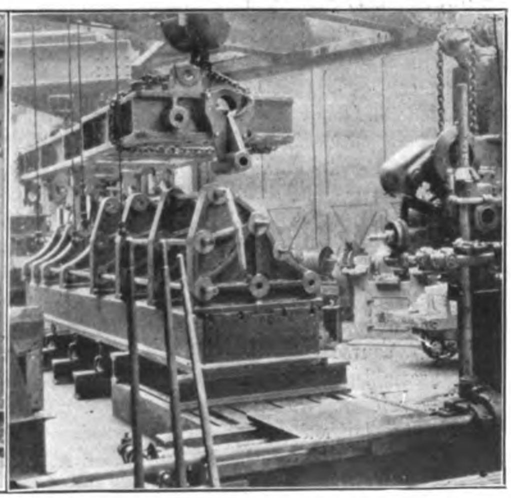

FIG. 23. ANOTHER VIEW OF MASTER JIG

curely boxed, as in Fig. 21, to prevent any damage in transit. This practice costs more money, but saves time and trouble.

In order that each working group may work independently, each is supplied with an aligning jig. These jigs weigh approximately 4 tons each and are made from a master jig. The latter is unusual in that it is composed of bushing brackets accurately made, which may be arranged on a huge grooved bed, as in Fig. 22. Suspended on crane chains just above is a jig that may be lowered to the plate and bored as desired. Another view of the master jig is seen in Fig. 23. In the foreground is a Beaman & Smith horizontal boring mill. The boring bars are connected to the machine spindle by a double universal joint, the bars themselves being guided by the steel ground bushings in the master brackets. This method is bound to produce duplicate jigs, and the parts of one machine are interchangeable with those of any other.

The size and number of castings required to supply the assembling shop when running on a large order precludes any one foundry from doing all the work or any one set of patterns from sufficing. For this reason a large number of duplicate patterns were made, requiring the work of over 100 men for two months. A three-story furniture factory furnished the necessary machinery and space. One of the sets of patterns for the No. 20 machine, with its core boxes, requires all the space in a furniture car for shipment, and all the patterns on hand would load 30 freight cars. There is another trainload of jigs. The production of 200 tons of machine tools daily means rapid handling all along the line, and in the assembly shop the work is of an extent that would be impossible unless everything had been built special.

The assembly building, known as the south shop, is 44x300 ft., and some of its main features are outlined in Fig. 24. A railroad track runs close to each side, so that castings are unloaded at a door on one side, take a diagonal course almost directly across, emerge completely assembled and are loaded on a car at the other side. By referring to the plan it will be noticed that the doors are labeled A5, B5, A6, B6 and so on. This means that the doors of the same number represent the places of entrance and exit. Two 5-ton cranes are available to serve each machine, if necessary. Ten of these cranes, each worked by two motors and capable of revolving entirely around its columns, are placed down the length of the shop. The only columns in the building are the crane columns. The trusses are supported on the wall opposite and cantilever across the columns. Water and gas are supplied at each crane, and also alternating and direct electric current. The astonishing thing is that this entire building, with its fittings, was completed in 18 days from the laying of the foundation.

The preliminary preparations for the manufacturing operations included an enormous number of details. Nothing, however small, that would assist the speed and accuracy desired was overlooked. One instance is that double-thickness pipe was obtained for rollers under the frames while in the shop. Their thickness prevented crushing, and each gang was supplied with sets already cut to the required length for convenient use. Enormous stocks of other material were purchased, and the Amalgamated owns and has in its actual possession what is probably the largest stock of steel of its special sizes in the country. No cold-rolled stock whatever is used, as it has an end grain as well as a surface tension rendering it unfit for the Amalgamated's purposes. As previously stated, only openhearth, 50-carbon steel, turned and ground to extreme limits, is employed. All other parts, such as gears, collars and the like, are made by specialists who are held to rigid inspection limits.

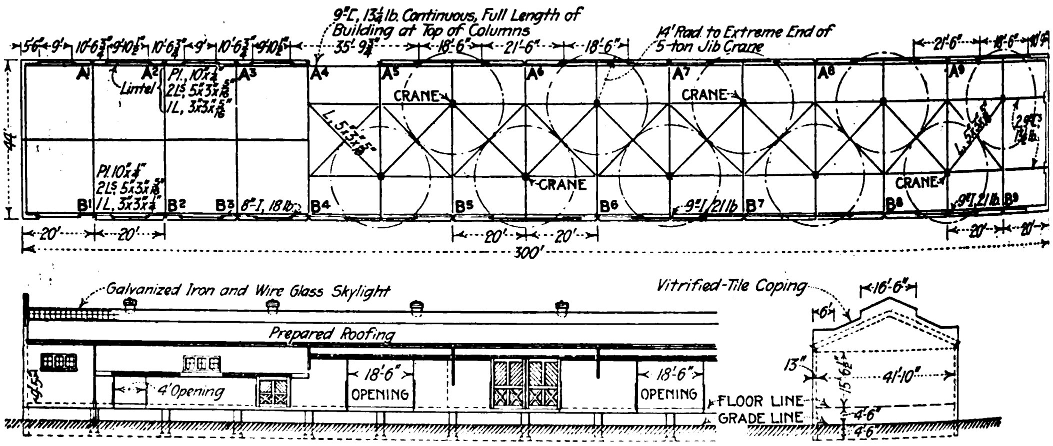

FIG. 24. SOME OF THE BUILDING DETAILS

Power Needed for Wire Drawing

Kenneth B. Lewis, in the *Blast Furnace and Steel Plant* for December, 1915, gives a formula for the horsepower required to draw wire. It is the result of some 60 motor readings made under known conditions and covering a wide range of size and quality of material. The formula is

$$Hp. = T\,(A - a)\,S\,\frac{F}{33{,}000}$$

where

T = Tensile strength of stock before the draw, expressed in pounds per square inch;
S = Speed of draw in feet per minute;
A = Area of wire before the draw, in square inches;
a = Area of wire after the draw, in square inches;
F = Factor selected from the accompanying chart.

Spring Fever in the Small Shop

By John H. Van Deventer

SYNOPSIS—This is a "Dave Hope" story, telling how the inmates of his small machine shop were afflicted with spring fever and how they were cured by inoculation.

There is a disease not mentioned in the medical books. It spreads its influence broadcast over the country each year and spares not rich nor poor, young nor old. It affects most strongly those whose occupations keep them within doors and is a disease that every machinist's apprentice and even the machinist himself suffers from each year. The germs of this disease are frozen up and harmless during the winter season; their busy time is the month of May:

When the buds begin to blossom
And the bees begin to hum;
When you feel like playing 'possum
And your job seems on the bum.

It is at this season of the year that the machinist in the large or the small shop picks out a soap box or nail keg as a resting place from which he can with the least effort observe the slow progress of the thirty-second-inch feed crawling over the surface of the work. But while his eyes are on the machine, his thoughts are elsewhere. In imagination he is feeling the warmth of the sun upon the back of a neck that has been protected from sleet and storms for many months by an upturned coat collar. He is imagining the satisfaction of indulging his five senses, individually and collectively, with the sights, sounds, smells, tastes and feelings of a rejuvenated earth. And just about the time when his imagination takes him to the crystal-clear inland lake crammed with fish as hungry as starving wolves—bang! The whole thing is punctured by the sarcastic voice of the boss: "Get rid of that hookworm and double up on your feed!"

Symptoms of Spring Fever in Dave's Shop

There were obvious signs that this spring malady had attacked Dave Hope's small shop. One convincing symptom was evident in Sandy McPherson's location out of doors, for he had moved the portable work bench from within and was doing his filing under the sky instead of under the shop roof. Reddy Burke, whose duties confined him to a close proximity to machines not so easily portable, looked rather disconsolate. As for the boy and the half-dozen other men who comprised the personnel of the shop, the evidence of the disease was unmistakably written upon them and displayed in every motion.

Dave Hope had not overlooked these indications and, in fact, felt some of the symptoms working in his own system. "This thing is going to cost us some money," he reflected, "because the trouble is sure to last for two weeks at least. During this time one after another of the boys will be taking a day off now and then, and it isn't in my disposition to tell them no, for I'll probably be doing the same thing myself." Just at this moment his eyes rested upon the magazine section of the preceding week's Sunday paper, which happened to lie open at article entitled "How Disease Is Made Harmless by Inoculation." "By George!" exclaimed Dave to himself; "I wonder if there isn't a way to inoculate against spring fever."

He read the article with considerable interest and found that the principle of inoculation is to treat the system with a dose of the disease bacillus that causes the complaint. "Looks like a case of fighting fire with fire," muttered Dave, lapsing into a period of silent reflection that lasted several moments. Then he got up, slapped the desk with his fist and ejaculated, "By George, I'll do it!"

Dave Gets Ready to Try the Inoculation

Next morning Dave did something that it was very unusual for him to do; he lined his men up and made a speech to them. Perhaps it should be called a talk rather than a speech, for there was nothing formal about it any more than about Dave himself.

"Boys, we're all coming down with a bad case of spring fever. I've got it myself, and I know that you have. And I don't blame you for it. But there are some orders here that we've got to get out—that 12x12 engine for Jones' sawmill, the road roller for the town and that duplex pump for Tim Ebbets. Now I'll tell you what we'll do—you boys pitch in and clean these up by Friday night, and we'll shut down until Monday morning, with the condition that all of us together go out for a two days' camp in the woods."

The speech of an eloquent statesman was never received with any more enthusiasm than were these few words of Dave's. All hands pitched in with a vigor that gave evidence of the success of the first inoculation.

Starting Off for the Camping Grounds

On Saturday morning at sunrise the wheels of the one-horse farm wagon creaked under the load of eight men and a boy and sundry equipment in the nature of provisions and camp material. Fishpoles were a prominent feature included in this assortment of goods, for every small-shop man is instinctively a fisherman by second nature. Dave had suggested that the party go on foot, thinking that the spring-fever inoculation would take place more rapidly under such circumstances, but compromised on a farm wagon without springs.

It was very pleasant jogging along the fresh-smelling country road, and the occasional bumps encountered by the springless farm wagon as it rolled over furrows left by recent freshets did not cause any lessening of the enjoyment, unless it was on the part of the boy, who was jolted off the back of the wagon by an unusually severe bump. As the sun grew hotter and the road grew hillier, it was necessary for the party to get out of the wagon and "spell" the horse, who seemed to be suffering from spring fever himself. Coats came off one by one, and beads of perspiration began to bathe newly acquired sunburn. Dave had chosen the road and had taken care to pick one with very little shade.

"Gee," said Tom, the boy, "I didn't think it could be as hot as this in May!"

"Hot, is it?" exclaimed Reddy Burke. "T'ink of the poor byes in Mexico—this is a rayfrigorator be comparison."

The destination of the campers was an inland stream girded by woods. It was a location seldom visited by fisherman, being 18 miles from town and 10 miles from the nearest railroad, and for this reason might be expected to furnish exciting sport and appetizing meals. The country in this neighborhood was sparsely settled, but a farmhouse was encountered some six miles distant from the creek, and Dave stopped the wagon to buy some fresh milk and to have a word in private with the farmer.

A Raid on the Commissary Department

The two days' supply of eatables in the commissary department had begun to melt under the attack of nine hungry appetites. "If you lads dinna refrain frae eatin' the noo, we will have nowt for breakfast the morn's mornin'," cautioned Sandy.

"We'll have fresh fish for breakfast anyway," replied Bill Evans; "there's a dozen breakfasts and dinners too, swimmin' in that there creek."

Upon arrival at the destination the horse was unhitched from the wagon and tethered in a shady patch of woods. Fishpoles were hurriedly sorted out from among other contraptions, Reddy Burke finding difficulty in unearthing his from beneath the big fly tent that had been brought along for sleeping quarters.

There was a rush for strategic positions on the bank of the creek. Sandy McPherson was the first to get into action, baiting his hook with a "night walker" the size of which insured an ambitious catch if any at all. Two minutes later, while Sandy was lighting his pipe, a ferocious and unexpected pull yanked the pole from his left hand. It was a steel pole, and not having the buoyance of the more common wooden kind, it disappeared beneath the surface, followed by a shower of Scotch imprecations.

"Hoot, a beastie wi' sic a pu' can be nae less than a hippopotamus," exclaimed Sandy, after he had cooled down a bit.

This experience heightened the anticipation of the rest of the party, proving as it did that there was big game in the creek. And in confirmation of this, Reddy Brooks' pole began to bend vigorously. "Begorry, I hov the baste," exclaimed Reddy, "and it's mesilf that will bring the craytur safely to terry firmmy."

Reddy Burke Catches a Big One

Then ensued a momentous struggle between an excited Irishman at one end of a fishpole and a fish of unknown species at the other. The battle waged with varying success for a half-hour, the rest of the boys dropping their poles and offering varied suggestions as to the best way of landing the catch. Finally, human skill aided by the elasticity of a fishpole conquered. "Get ready to hov a look at the biggest fish in the counthry," exclaimed Reddy, shortening up on his line. But it wasn't a fish—it was a gigantic snapping turtle.

That place seemed to be the headquarters of the snapping-turtle trust. One after another received promising bites, only to find them given by these hard-shell creatures who monopolized the stream. So many hooks were lost in this pastime that the fishermen discontinued their fishing and sought the shade of near-by trees.

The noon repast finished up most of the provisions. It was followed by a nap for all of the party but Dave, who seemed to have business back in the woods. So soothing was the outdoor air of spring that, when the amateur campers awoke, it was after 6 o'clock and they were as hungry as wolves. By unanimous consent they started for the wagon. But when they reached the clearing where it had been left, they was no sign of either horse or wagon!

Mysterious Disappearance of Board and Lodging

"Sure, 'tis a likely place for the fairies," exclaimed Reddy; "but if they bewitched the baste and the wagon, they've left tracks behint thim to indicate it." Here he pointed to unmistakable wheel and hoof prints. "Some dhirty rascal has cabbaged the commissary department!"

They succeeded in following the tracks as far as the crossroad, but here the wind had obscured the marks and the men were not enough skilled in woodcraft to detect which branch had been taken. Besides, it was growing dark, they were without shelter, and the evening breeze began to feel chilly.

"The best thing for us to do," advised Dave, "is to find some barn where we can sleep. The nearest farmhouse is six miles away, and I suggest that we follow the creek road, where we may find something nearer."

A six-mile walk without supper did not attract the rest of the boys, and it was agreed to try the creek road. It was quite dark by this time, and everyone had parted with his last bit of good nature. Tom, the boy, apparently could see in the dark better than any of the others. "There is a building over there, I think," he exclaimed, after the party had trudged a half-mile by starlight. "If you fellows will wait here a minute, I'll go over and see what it is."

He came running back in a few moments. "It looks like a good place to sleep," said he; "it's a shed with a lot of sawdust on the floor."

Reddy Burke Has a Nightmare

Reddy Burke woke up two hours later from a nightmare in which he, a morgue and a slab of ice played the principal parts. He found that he had sunk downward quite a bit in his bed of sawdust, and he was surrounded with icy cold water. "Wake up, lads," he bellowed at the top of his voice, "the creek is rising and youse will all be drownded!" Someone struck a match, and by its flicker they could see that they had gone to sleep in an icehouse!

Two hours later the moon looked down on a disconsolate party trudging back toward town. It was almost dawn when they came to the farmhouse where the milk had been obtained. "Guess I'll run in here and see if the farmer has seen anything of our horse and wagon," said Dave.

He did not have much trouble in arousing this gentleman, who led him back to the barn and the missing conveyance. "Wall, I reckon you're satisfied that I followed directions all right enough, aint ye?" said the farmer, with a sly wink as he pocketed Dave's two-dollar bill.

The horse ambled along with his load of homeward bound pilgrims, quite unconscious of the verbal abuse that was heaped upon him by men who were too tired to sleep and too angry to converse.

Sunday was spent at home in bed by the members of the camping party; and when they returned to work on Monday morning, the spring-fever inoculation was complete. Even Sandy McPherson moved his work bench back into the shop.

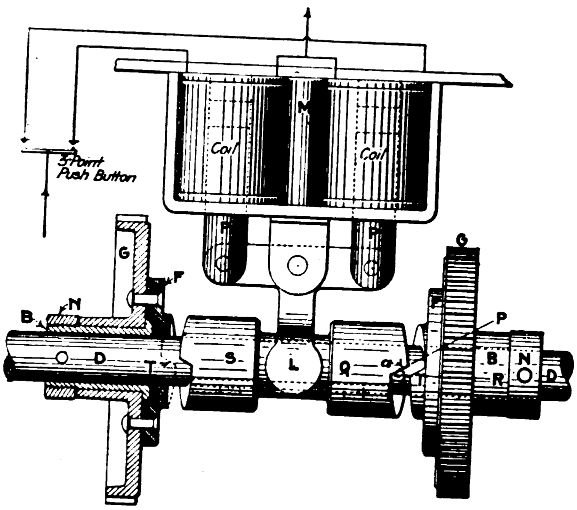
Magnetic Clutch for Machine Application

By Jan Spaander

Except for lifting purposes, electromagnets are seldom used in the machine shop. This is partly because the possibilities of the magnet are not generally understood and partly because the machine-shop man, as a rule, is not aware that a two-coil full-time magnet in four cases out of five can be installed at lower cost and in a more convenient place than a system of levers.

The two-speed mechanical-magnetic clutch shown was built to perform two operations on a drilling machine that required the full attention of the operator to obtain good work at a reasonable price. The clutch did not call for attention at all. It worked silently, and it did wonders.

The two gears *G* are idlers on the bushing *B* and, with their nuts *N*, are pinned to the driving shaft *D*. The gears are riveted to the flanges *F*, in which jaws *T* are cut. The sleeve *S* is keyed to the shaft in such a way that the



MAGNETIC CLUTCH APPLIED TO A DRILLING MACHINE

lever of the magnet *L* can slide it in either direction and thus engage one of the gears. The jaws at the ends of the sleeve correspond with those in the flanges.

The jaws slope in such a way that, if there is no current on the magnet, the axial component of the tangential force on the jaws is slightly greater than the friction of the sleeve on its keys and the sleeve is gently pressed back to its central position, disengaging the machine automatically.

The magnet is built out of a frame of flat iron, two commercial full-time coils and two iron plungers *P*. The coils receive their current from a three-point switch or push button, as shown. This contact maker is placed near the foot of the operator.

If the angle *a* of the jaws is well chosen, the friction on the keys and the axial force balance; and the energy consumed to keep the clutch in can be very small. The calculation of this angle seems formidable indeed, the friction and the forces involved being unknown quantities.

However, the angle can be found in a practical way within a couple of minutes by putting one of the two keys on a strip of the material of which the sleeve is made. By lifting one end of the strip, the key will slide at the angle of friction, and the angle of friction practically equals the angle *a* of the jaws. The points of application of the forces on the keys and on the jaws are practically equidistant from the center of rotation and therefore equal.

Blueprints Without Tracings

By A. Spalding

The popularly accepted manner of making drawings to be reproduced by blueprinting is to transfer a pencil drawing on heavy paper to tracing cloth, which means a double operation in getting the drawing on a medium suitable for blueprinting. While this practice has the advantage of giving drawings on a durable material, which may be justified in cases where many blueprints are to be made, it is nevertheless expensive, and needlessly so, for a great amount of work.

There are on the market several grades of bond paper, in different weights and suitable widths, with sufficient body for drawings. From these surfaces blueprints may be successfully made, thereby eliminating the necessity of tracing and also reducing the cost of the drawing from 25 to 50 per cent. While bond paper is most suitable for details, it may in many cases be used for complicated assemblies.

The only precautions needed in making drawings on bond paper is to use a sufficiently soft pencil to procure a dense black line—a 2-H pencil is suitable. Also, on account of the paper being thin, as compared with the usual drawing paper, it may be found necessary to fold the corners over a couple of times where the sheet is tacked to the board, in order to prevent tearing.

Where this system is adopted, it is well to file a limited number of drawings in cardboard folios that may be taken from the file for the removal of individual drawings. Thus tearing or wrinkling, due to the weight of superimposed drawings, when taking drawings out of, or replacing them in the file, is avoided.

For office reference it is preferable to use a blueprint rather than the original, although the heavier grades of paper are very strong. Acid-treated tracing paper, which is brittle and tears easily, should not be confused with the bond paper mentioned.

In addition to plain bond paper pads of 100 sheets of a ruled cross-section paper in 8½x11-in. size or thereabouts, printed if desired with a suitable heading consisting of the firm's name, space for title, drawing number and date, are found to be admirably adapted to the rapid reproduction of details. These sheets may be sketched without a scale or straight-edge, using the section lines as a substitute. With this paper it may be found preferable to use ink, to avoid possible confusion on the blueprint, because the section lines may also show faintly.

However, it has been found in many cases where the draftsman has the detail sufficiently well in mind that he can draw it (to scale if necessary) freehand by following the cross-section lines. A so-called ball-pointed pen has been found satisfactory for this work.

In making the blueprints about double the usual time of exposure is required. This item is not serious, because of the cheaper labor employed to make the prints.

Punches and Dies for Making Pepper and Salt Tops

By Robert Mawson

SYNOPSIS—In this article are shown the punches and dies used in manufacturing pepper and salt tops.

The H. O. Rogers Silver Co., Taunton, Mass., manufactures a variety of high-grade silverware. An example of this work—silver pepper and salt tops—is interesting and is here described. It will be seen that the various operations are performed at a good rate of speed, which is given. The tools are of a simple design, but they produce parts of a high-grade order. The machine for rolling the thread is shown in Fig. 10, while one of the finished parts is illustrated in Fig. 11.

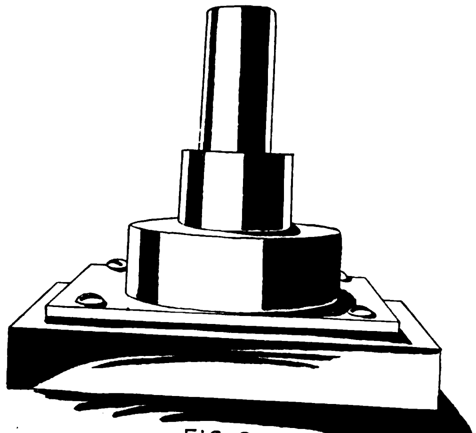


FIG. 2

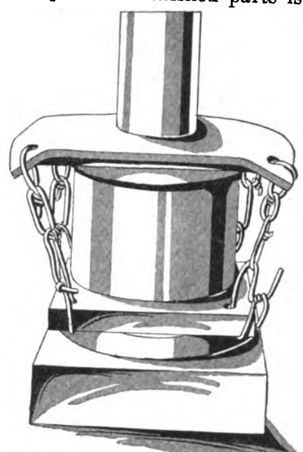

FIG. 4

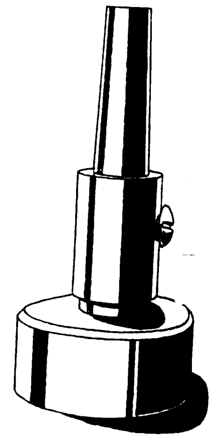

FIG. 6

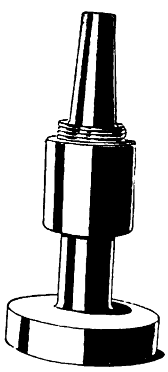

FIG. 8

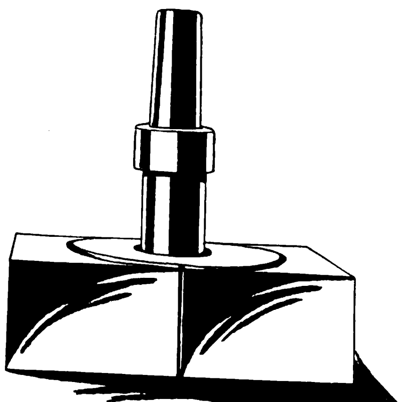

FIG. 9

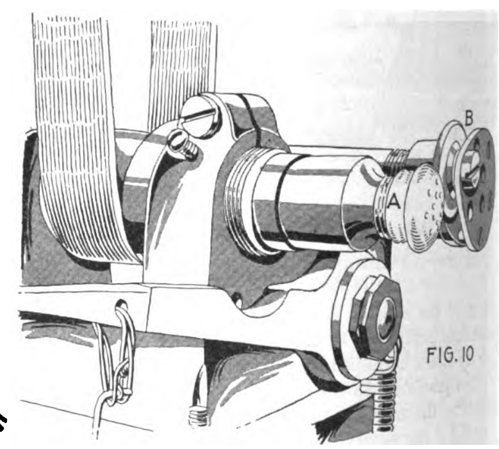

FIG. 10

PUNCHES AND DIES FOR MAKING PEPPER AND SALT SHAKER TOPS

FIGS. 2 AND 2-A

Operation—Blanking out disk, Fig. 1. The stock, which has been cut to the correct width, is fed under the stripper. As the punch descends, the disk is blanked out.

FIGS. 4 AND 4-A

Operation—Drawing the blanked disk to the shape shown in Fig. 3. The disk is placed in the recess formed in the die, and the punch is forced down. The machined projection on the punch holds the blank in position on the die. As the punch descends farther, the rubber pad is compressed and the internal punch gives the required shape to the disk.

FIGS. 6 AND 6-A

Operation—Rolling the edge to the contour seen in Fig. 5. The drawn blank is placed so that it rests on a shoulder at the lower end. The punch is moved down by the press, and the upper edge of the blank is rolled over by means of the shoulder at the upper end of the punch.

FIGS. 8 AND 8-A

Operation—Perforating the upper end, as illustrated by the detail, Fig. 7. The rolled blank is placed over the machined shank of the die, which is a good fit. The punch, which is provided with steel punches of the size and number to suit the part to be produced, is forced down by the press, and the holes are perforated in the top.

FIGS. 9 AND 9-A

Operation—Bulging the perforated top. The piece is placed between the two die elements, which are made with a similar contour to that desired for the top. A rubber plug is placed in the hole of the piece, and as the punch is forced down by the press, the rubber is compressed and the top pushed out to the same shape as the die elements.

FIG. 10

Operation—Rolling the thread. The top is slid on the threaded arbor A, and as the wheel B is fed along it with the arbor revolving, a similar thread is rolled on the top.

DETAILS OF PUNCHES AND DIES USED IN MAKING PEPPER AND SALT SHAKER TOPS

The Engineer, the Public and Economics

By A. L. Haas

In his consideration of modern progress or in his survey of industry the economist divides the past into two distinct periods, the separating point being the utilization of power by the introduction of steam. This factor, leading to improvement in textile machinery, together with the invention of the lathe slide rest, forms the keystone that sustains all recent progress. Antiquity offers evidence of huge works accomplished—the pyramids are one example—but such work was in the main apart from economic consideration altogether.

An engineer may be defined as one who guides, directs, controls or takes advantage of natural forces to serve utilitarian ends. In a modern sense the necessary qualification is that the results achieved must lessen cost. Much of the work of the past served no utilitarian end, nor was it of direct commercial benefit to the community at large. Modern effort is alone commercially communal and can be considered upon the ground of direct utility.

Much criticism has been passed upon engineering work as inartistic and unbeautiful. The correct reply is to insist upon its commercial benefit rather than its infraction of the canons of art. The question of beauty versus utility will always be arguable and find reason to back both points of view. Where, as in some large work, the two opposing factors can be combined (as they have successfully been at times), there is agreement in place of opposition.

Engineer—The Tool-Using Superman

Man is separated from all other life by one clear distinction. He uses tools. The engineer is separated from other men in that his tools are of supersize. He is the tool-using superman. If merit rests in the first distinction, then obviously greater merit rests in the second.

The functions of the engineer are purely economic, his ends frankly utilitarian. He will harness a picturesque waterfall to the basest of power uses without his conscience feeling in the least uneasy. He will alter natural features by schemes of irrigation and transit. He is the true evolutionist of the modern era, and nothing he does is devoid of use or service to the community. Apart from engineering effort modern wealth would not exist. In more senses than one he creates wealth as does no other section of mankind. He conserves energy and renders practical the otherwise impossible of achievement. Today he wages war and in at most a few short years will certainly render war impossible.

He takes the bare results of scientific discovery and adapts them to universal benefit. He renders time-wasting and cumbrous methods obsolete, gives improved means to effect the laborious and the menial work of the world and dignifies manual labor by removing its worst features. Simple muscular work is rapidly passing away, and skill is being placed in front of mere muscle—all because of engineering effort. Those professions most in the public view are largely those whose stock in trade consists of words. The engineer's busy doings are inarticulate, and he remains more or less a mystery to the public at large.

As an organizer and economist of front rank no other member of the community has the engineer's opportunity of acquiring the same vital experience. He combines the human and the material as does no other man. In spite of this, or perhaps because of it, his place in public affairs has in the past been a minor or a secondary one. This is to be lamented and it is hoped, will soon be remedied. As a servant of the community at large the engineer's efforts have been second to none. He is therefore qualified to take a place in public affairs as are few others in the nation.

It may be on account of the inherent modesty of genius, or because his time is occupied and his life a satisfying one—perhaps it is because he does not yet realize that the qualified technical man is the equal of those in any other profession extant—that his voice is more or less silent in public affairs. Whatever the reason, it is to be regretted.

Were the public at large more acquainted with the engineer's value and worth, it would certainly welcome his guidance in problems already solved in manufacturing, but which seem beyond the capacity of those vested with elective authority.

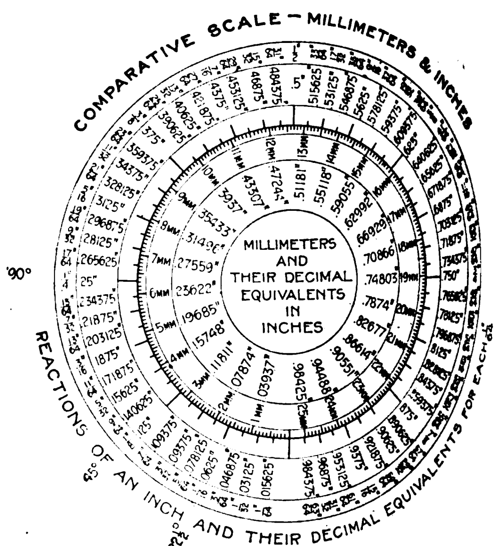
Handy Metric and Decimal-Equivalent Scale

By Norman V. Christensen

There is hardly a shop but what uses the metric system at least occasionally; and this tendency is on the increase, largely owing to the present conflict in Europe.

The accompanying scale is practically self-descriptive, but a little explanation will be helpful.

The circumference of the heavy circle represents 1 in., and as will be seen, the outer ring of figures indicates



HANDY METRIC AND DECIMAL EQUIVALENT SCALE

the fractional parts of an inch and their decimal equivalents. It will be observed that there is little chance for confusion.

The millimeters are marked off on the inside of the circle and show at a glance what any number (under 25) equals in inches. For example, take 13.5 mm. and it will be seen that it is just $\frac{17}{32}$ in.

Manufacturing British 8-In. Shells in 4½ Hr.--II*

By Fred H. Colvin

SYNOPSIS—The method of cutting the wave groove is interesting, special tooling being used. Using taps and dies of nearly 5½ in. in diameter on long threads in fairly high-carbon steel is unusual enough to be of special interest, especially when an 8-thread is cut at the rate of 1 in. advance per min. The shells are varnished by flooding. The instructions for inspection are also noteworthy.

The wave groove for the band is the succeeding, or eighth, operation, for which another Root & Van Dervoort machine is made to serve by using a special turret and a bolt and then turns the turret. This arrangement gives a particularly convenient mode of operating tool-post turrets of this kind. Then comes the first government inspection for the operations as far as they have proceeded.

Banding is done on the West hydraulic machine, the band being heated in a Stewart gas-burning furnace. Considerable experimenting was necessary to secure entire satisfaction in this operation, as it is a large band to force into place so as to fill completely the undercut at the side of the band groove.

After trying various heats running as high as 1,400 deg. F., it has been found that 1,150 deg. F. gives the best results with about 2,400 lb. pressure, there being three squeezes in order to seat the ring properly in every way.

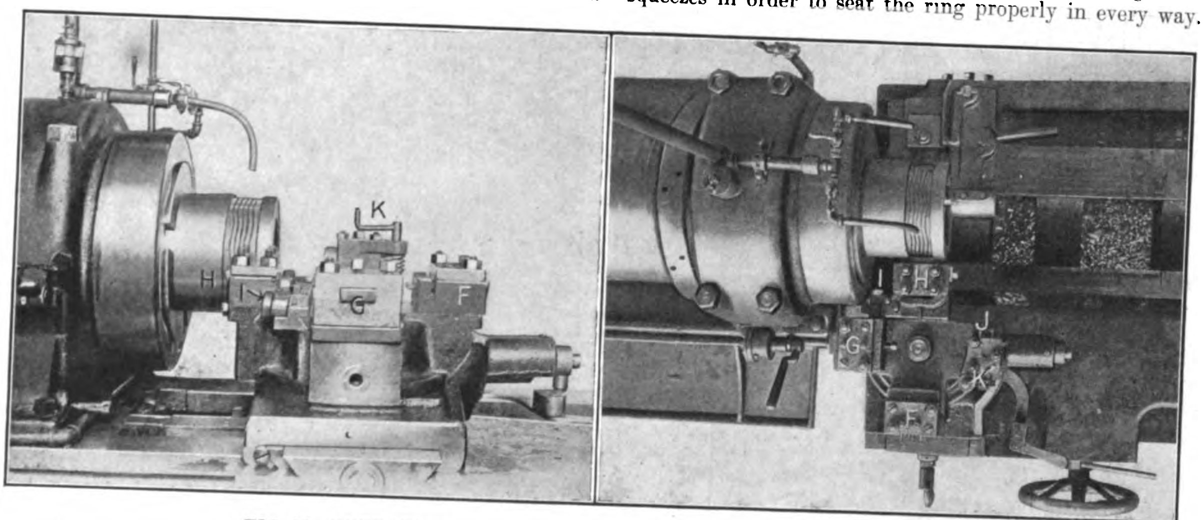


FIG. 15. OPERATION 9: CUTTING WAVE GROOVE—SIX SUBOPERATIONS

Machine Used—Root & Van Dervoort special.
Fixture and Tools—See Fig. 16.
Gages—Diameter, width, wave and undercut.
Production—20 min. each.

cross-slide, Fig. 15. They are shown in detail in Fig. 16. There are six suboperations in making this wave groove. First, two parting tools *A*, Fig. 16, come in from the back and cut down the side of the groove. Then a tool block *B* is swung in from the pivot *C*. It carries the tool which chamfers the end of the shell and faces it square with the groove for the banding operation. The tool was originally used to undercut for the thread in the base, but this work is now provided for in a later operation.

Then six grooves are cut in the band space by a gang of parting tools *F*, to break up the width of the chip, which would be about 2 in. wide. The metal that is left is faced down with the flat cutter *G*. The waves are then cut with the formed cutter *H* by means of the wave cam on the face of the chuck and the roller *I*. The sides of the groove are undercut by two tools *J* moving at the proper angle and controlled by the handle *K*, which operates through a worm and racks on the back of the tools. The indexing is by the side handle, which first withdraws the

*Previous installment appeared on page 749. Copyright, 1916, Hill Publishing Co.

It was also found that the width of the ring plays quite an important part in having it fill the undercut. Best results are secured by turning the ring to $^1/_{64}$ in. less than the minimum width of the groove when cold. This means that a slight shaving takes place from the ring when it is forced into place, but it insures enough metal at the bottom of the band groove to flow nicely into the corners of the undercut. Fig. 17-A gives the band dimensions. Production time, 3 min. each.

Next come the counterboring and threading for the adapter plug and for the open end of the shell, Fig. 18-A. The threading operation and the plug itself are both interesting. The shell is held in the same type of lathe as for cutting off in the second operation. The tools consist of a boring bar and a Murchey tap, mounted in a specially heavy turret. When the toughness of the steel is considered and also the fact that this thread is 5.435 in. in outside diameter with an 8-pitch, left-handed Whitworth thread, it will be seen that considerable metal must be removed at each tapping operation. The shells are bored, counterbored at the end of the thread and the tap run in at 10 r.p.m., making exceptionally fast threading for this

Production—5 min. each.

diameter. A finishing tap is also used, in order to maintain the thread size. Production time, 15 min. each.

The thread is then cleaned out with a brush and an air jet, and the adapter, which has been previously made, is screwed into place, as in Fig. 19. The shell is held in a clamping stand, Fig. 14, for this, the eleventh, operation.

With the adapter screwed in place, the large end of the shell must be faced to weight on the lathe shown in Fig. 20. The shell is held in a regular draw-in chuck.

Over this lathe is a jib crane that carries a beam scale, as can be seen. Suspended from it are the chain hoist and shell clamp. The shell is first weighed, then placed in the chuck, and the proper amount is faced off according to a table that is hung up in plain sight at A. A few of the main equivalents are shown herewith, from which it will be seen that facing off $\frac{1}{32}$ in. of both shell and adapter plug reduces the weight 6¾ oz., while $\frac{3}{32}$ in. gives 1 lb. 4 oz.; and ¼ in., 3 lb. 5¾ oz. This system

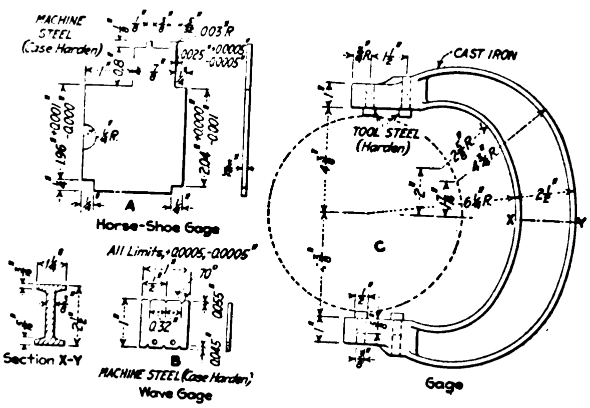

FIG. 15-B. GAGES FOR OPERATION 9

makes it easy to bring the shells to proper weight very quickly and with a degree of accuracy that largely reduces the cut-and-try plan.

After facing to weight, the end is again stamped with the heat number and other symbols, as in Fig. 21-A, this work being done by hand through a specially made guiding plate. The adapter plug is removed for cleaning the inside and varnishing, an electrically driven drill properly geared down serving for this purpose. The way in which this is done is shown in Fig. 19, the motor being suspended and counterweighted for easy handling.

The shells are cleaned with hot soda and water by the arrangement shown in Fig. 22. It consists of a framework *A*, built up of wood and steel, into which the shells are set point down. The whole framework is then lowered into the tank of hot soda water, where it remains as long as necessary. The shells are next washed in plain water, after which they are ready for varnishing.

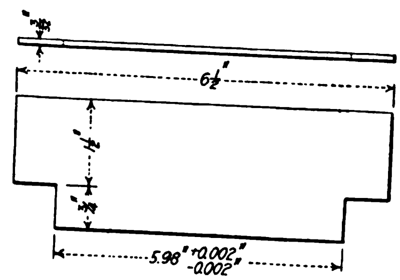

FIG. 18-B. GAGE FOR OPEN END OF SHELL

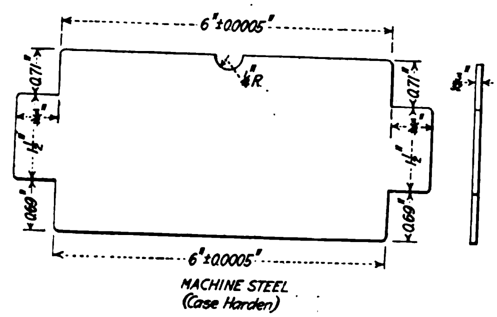

FIG. 18-C. LIMIT GAGE FOR OPEN END OF SHELL

The varnishing is done by a different method than usually employed. For this purpose special trucks, Fig. 23, have been made, the upper part consisting of a framework that carries 12 shells, nose down, in a cast-iron frame. The construction of this frame is given in Fig. 24, a bronze collar with the same curve as the nose of the shell being placed in the lower section to hold the shell firmly without bruising.

The truck with its load of shells is run beside the varnishing tanks, which are shown in outline in Fig. 25. One of the elbows, seen in place on the truck, is screwed into the nose of a shell, completely covering the threaded portion and thereby preventing varnish from getting into it. The elbow is then connected to a hose running to the varnish tank. Manipulating the three-way cock allows pressure from the air tank to force varnish up into the shell, which is stopped when the height reaches the recess below the adapter-plug thread. The air is then shut off, and the varnish returns by gravity to its tank, allowing just enough to adhere to cover the inside of the

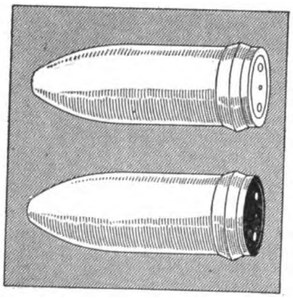

FIG. 20-A. OPERATION 13: FACE TO WEIGHT

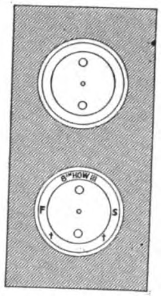

FIG. 21-A. OPERATION 14: STAMP END OF SHELL

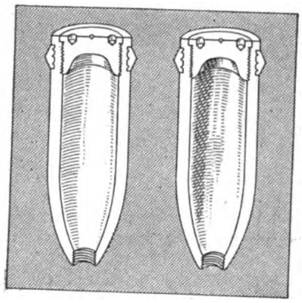

FIG. 22-A. OPERATION 17: VARNISHING INSIDE OF SHELLS

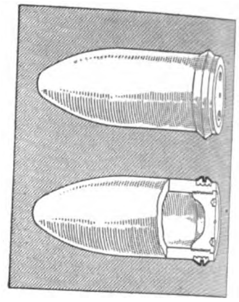

FIG. 26-A. OPERATION 18: TURN COPPER BAND

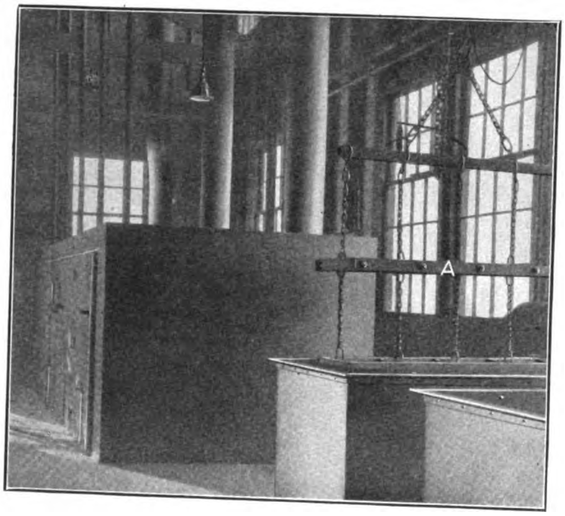

FIG. 22. SODA TANK AND OVENS

shell. With the elbow left in place, to prevent the varnish from running down into the thread, the truck load of shells is run into the baking oven, Fig. 22, where they are held at a temperature of 300 to 325 deg. for a sufficient period thoroughly to bake the varnish.

The bands are next turned on a short-bed Root & Van Dervoort lathe by means of two formed tools. The front tool merely roughs out the band to the approximate shape, while the rear undercutting or shaving tool gives it the final form, including the proper serrations at the point.

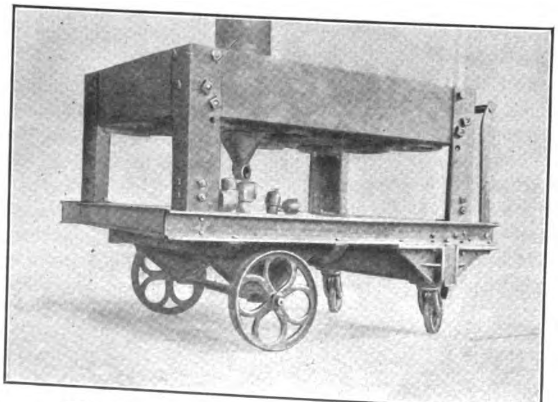

FIG. 23. SPECIAL TRUCK FOR VARNISHING

Final inspection comes next, after which the grommet or endless-rope band is slipped over the shell close up to the front of the upper band as in Fig. 27. The grommet remains on the shell, as it affords protection to the band, both in handling and in shipping. Then the plug is screwed into the body, and the shells are boxed for shipment, one shell in a box.

The adapter plug, which screws into the base of the shell, is made from a forging weighing 30 lb. The first operation, Fig. 28-A, is to face and rough-turn the head on a large Potter & Johnston machine, the regular tool equipment being used for this purpose. Next comes

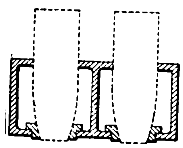

FIG. 24. SECTION OF TRUCK

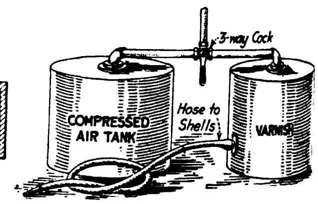

FIG. 25. THE VARNISHING TANKS

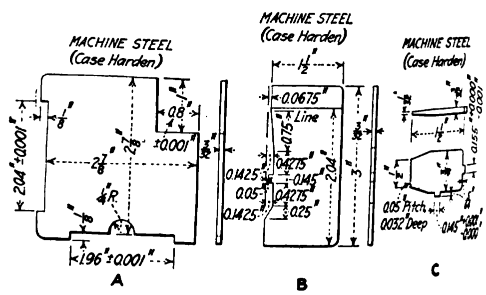

FIG. 26. GAGES FOR BAND, OPERATION 18

the drilling of the two ¾-in. holes for the pin wrench and also for holding in some of the future operations.

This operation is shown in Fig. 29-A and the drilling fixture in Fig. 30. The piece is chucked by the head and rough-turned on the outside, while the curved contour is also roughed out by flat cutters approximating the correct form. Both a Potter & Johnston machine with sweep cutters and a Root and Van Dervoort shell machine are employed. Special cutters are used with a hydraulic feed.

The plug is driven by two pins fitting into the wrench holes, while the plug itself it held by three chuck jaws. The holder *A*, Fig. 31, bolts against the face of the chuck and allows the jaws to act in the three slots shown, the driving stress being carried by the two steel pins.

Then the outside is finish-turned and the curved contour swept out to shape, the undercut for the thread being made at the same time, either on a Root & Van Dervoort or on a Potter & Johnston machine.

The thread is then cut under a Baker vertical heavy-duty drilling machine, Fig. 32, furnished with a Murchey self-opening die and a special knock-out that has been arranged particularly for this work. It consists of two fingers of small section, which go down between two of the chasers, opening the die when they strike the head.

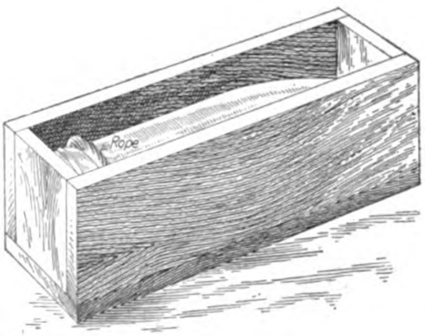

FIG. 27. GROMMET IN PLACE

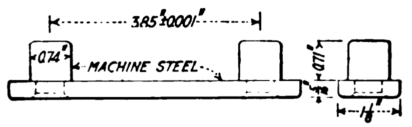

FIG. 29-B. GAGE FOR HOLES IN PLUG

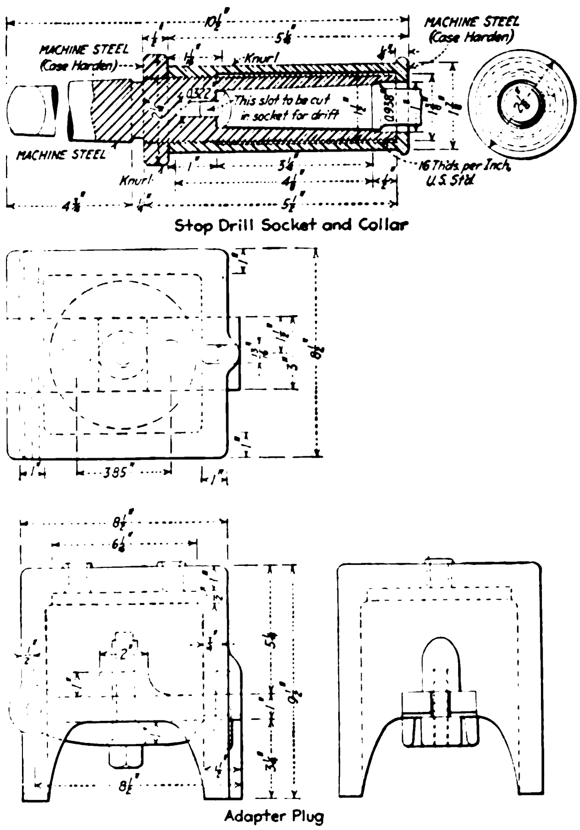

FIG. 30. DRILLING FIXTURE FOR PLUG

The thread is an 8 to the inch, of Whitworth form and left-handed, and the cutting is done at 8 r.p.m., using for a lubricant Sol-cut with a trace of tri-sodium phosphate added to it. It has proved much more satisfactory than the cutting oil that was first tried, as it leaves a better finish on the work and is apparently easier on the die.

The plug is held for threading by simply placing the two wrench holes over dowels in the holding fixture on the drilling table. The operator makes a small punch mark to show which way the plug was placed on the fixture for the first threading.

The feed is geared so as to lead the die at its proper rate, and the punch mark allows the plug to be replaced for the finish threading without difficulty. By bringing the die head down on a distance block before throwing in the feed, the proper lead is maintained, and there is no trouble experienced in catching threads. The finishing die removes $^1/_{64}$ in. and leaves a good thread on the plug. The roughing cut is taken at the rate of 8 r.p.m., while the finish cut is speeded up to 12 r.p.m.

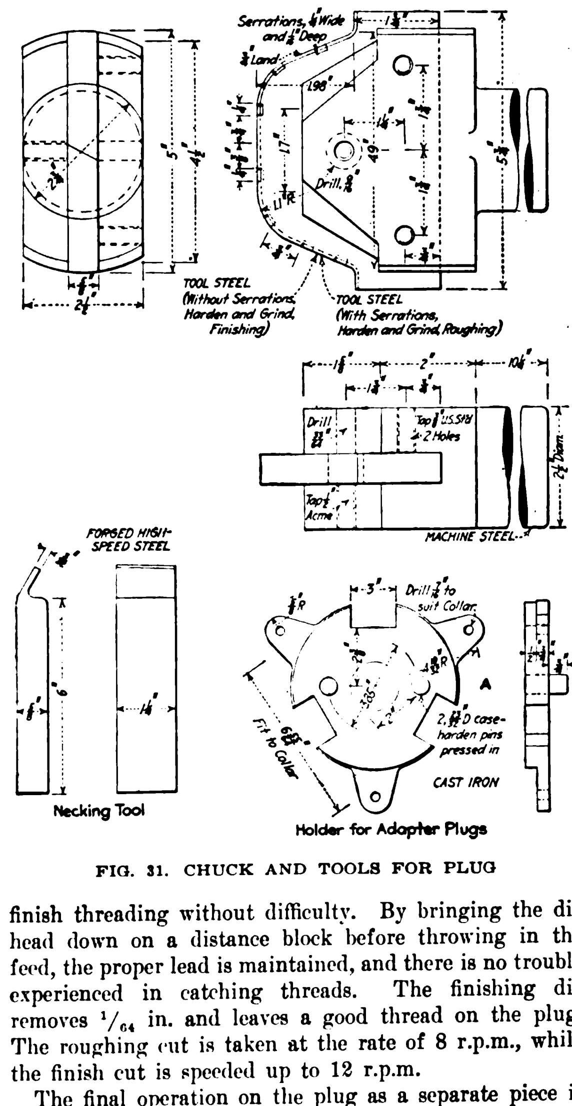

FIG. 31. CHUCK AND TOOLS FOR PLUG

The final operation on the plug as a separate piece is to screw it into a sleeve chuck, Fig. 33A, which bottoms it so as to allow the fillet to be turned and the under side of the head to be squared. The outside is then turned true with the thread, this being done on an engine lathe that happens to be available. The finished plug weighs about 19 lb.

The inspector's instructions are given, to show the special points to which they must give attention.

INSPECTION INSTRUCTION

Inspection of Rough Forging—The rough forging is examined for heat number and for the two acceptance marks. If the heat number should come directly on the nose of the shell, it is transferred by the inspector to the side of the nose of the shell. The shells are inspected for lengths, outside diameter and inside diameter, which is done by the use of calipers, and are also measured for concentricity by the use of a special concentricity gage.

From four to eight shells are placed on the bench by the inspector's helper, and the inspector does the measuring, carefully marking the amount of concentricity at the high point of the shell. This marking is done with a brush and yellow ochre. Shell forgings are piled so that all forgings eccentric ⅛ in. or more are in one pile, while forgings that come eccentric ⅛ in. or less are piled in another pile.

The forgings are also inspected for deep flaws or grooves. All forgings not coming up to requirements are held for the decision of the chief inspector, who in turn takes up any questions as to the availability of the forgings with the British inspector.

Operation 1: Drill and Rough-Face—The length of hole is carefully inspected by the use of gage provided. The inspector also looks through the hole in the nose of shell from the rear end, ascertaining if the hole is reasonably concentric with the bore. The inspector ascertains that there are no flaws in the hole.

Operation 2: Cut Off End—The inspector ascertains that the operator has transferred the heat number from the nose of the shell to the end which has been cut off. The length of the shell is ascertained by use of gage provided. The forging also is inspected for cracks or flaws.

Operation 3: Rough-Turn—The inspector ascertains that the outside diameter is within the limits according to special gage and also ascertains that the contour of the outside is according to the special gage. The diameter of the small end is carefully measured with a special limit gage which has not yet been made. The finish is examined, and care is taken to see that there is no step of appreciable depth in the forging, and also the whole exterior surface is carefully examined for flaws.

Operation 4: Rough-Bore—The inside diameter is checked with limit gages provided. The inside contour is checked with gage provided and the length of the hole in front carefully checked to see that same will clean up. A special gage must be provided for this. The interior surface is carefully inspected by the aid of a looking-glass and a small electric light, or other suitable means to ascertain that there are no flaws or cracks in the forging.

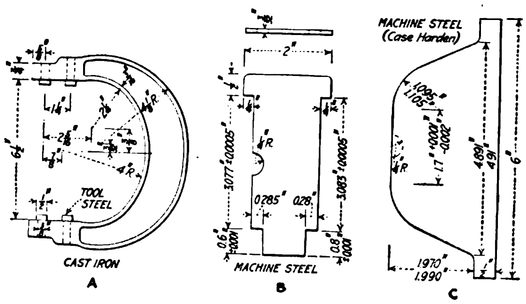

FIG. 31-B. GAGES FOR ADAPTER PLUG

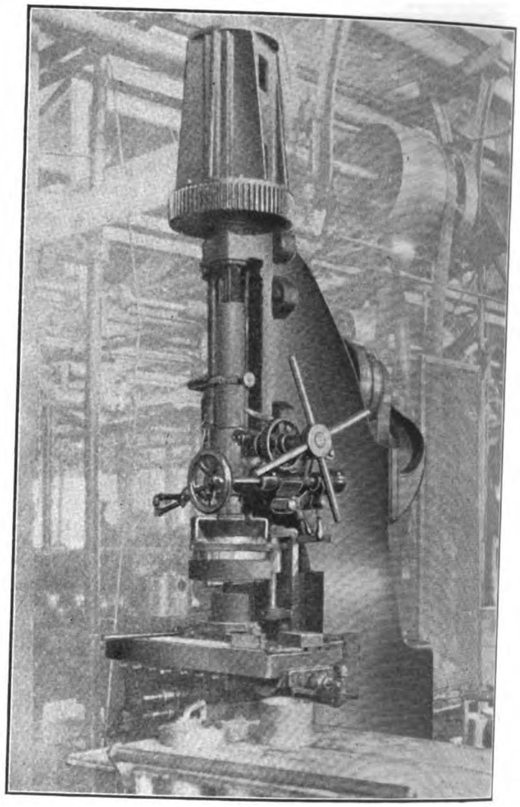

FIG. 32. ADAPTER OPERATIONS 5 AND 6: CUT THREAD WITH DIE

Machine Used—Baker heavy duty drill.
Fixture and Tools—Holder and Murchey die.
Gages—Ring thread gage.
Production—5 min. for rough, 4 min. for finish.

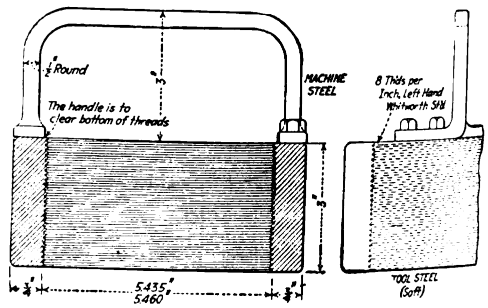

FIG. 32-B. GAGE FOR PLUG THREAD

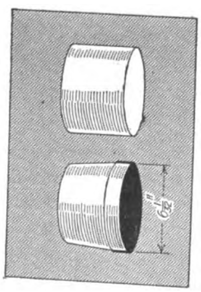

FIG. 28-A. OPERATION 1: ADAPTER PLUG FACE AND ROUGH TURN

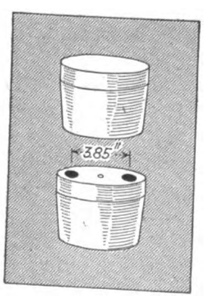

FIG. 29-A. OPERATION 2: DRILL WRENCH HOLES

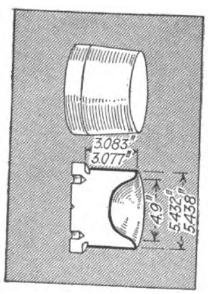

FIG. 31-A. OPERATIONS 3 AND 4: R. & F. TURN AND SWEEP

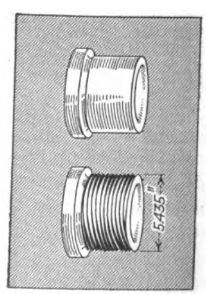

FIG. 32-A. OPERATIONS 5 AND 6: CUT THREAD WITH DIE

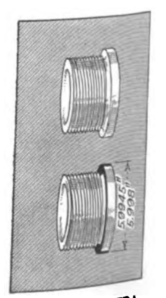

FIG. 33-A. OPERATION 7: SQUARE UNDER HEAD AND TURN

Operation 5: Finish-Bore—The inside diameter is checked according to gages. The contour of the inside is checked according to gages, and the general concentricity of the shell is ascertained by the use of callipers. The length of hole and nose is also carefully watched for, and a special gage is used which is not yet designed. Special care is taken to ascertain that the proper finish is obtained in the bore, any irregularities being cause for the rejection or holding for correction of the work. The shell is also inspected for flaws.

Operation 6: Bore and Thread Nose—The final stamping of the heat number on the rounded part of the outside of the shell is ascertained. The outside diameter in front of the copper band is checked with gages provided. The diameter of the sides below the copper band is checked with gages provided. The diameter of the face of the nose is also carefully checked, and a gage must be made for this. The outside finish is inspected and must be as good or better than the sample, which must be made.

The diameter of the side of the hole is carefully ascertained by the use of limit gages provided, and the diameter

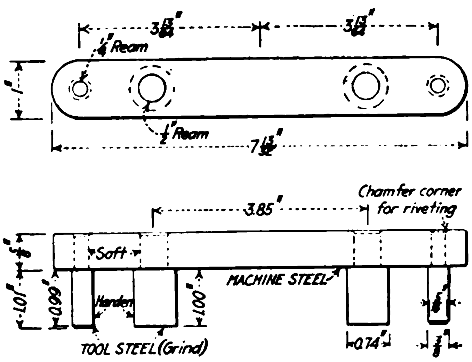

FIG. 32-C. GAGE FOR HEAD OF PLUG

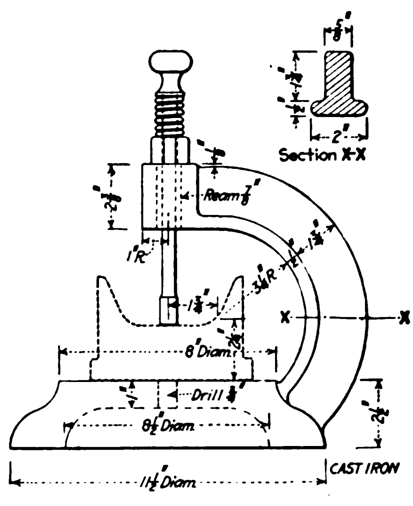

FIG. 32-D. MEASURING THICKNESS OF HEAD

and angle of facing are carefully checked. The finish of the thread is carefully inspected and is also inspected for flaws or chipping out in this thread.

Operation 7: Drill and Tap for Grub Screw—The distance of the hole from the face is ascertained, and size of the thread is tried with a tap used as a plug gage. The appearance of the thread is carefully checked, and if the thread causes a burr on the large thread in the nose the shell body must be retapped.

Operation 8: Wave Grooves—The width of the groove, the diameter at the bottom of the groove, the diameter of the waves, the throw of the waves and the amount of undercutting are carefully checked by the use of gages provided. The finish of the waves and the groove in general is carefully checked.

Operation 9: Bands—All copper bands are examined before they are placed on the shell, to ascertain that no scale is on the inside of same. After the shell is banded, the inspector tests the band by the use of a very small hammer, placing his left finger on the part near where he strikes a blow, and he can readily ascertain whether the band has been properly seated. Great care is exercised at all times so that careful inspection is maintained on this point.

Operation 10: Thread and Counterbore—The forging is carefully inspected for size of counterbore, for fillet at bottom of counterbore, for smoothness of machining, for correct size of thread and depth of same in relation to necking.

Operation 11: Clean Threads—The threads are inspected to ascertain that they are perfectly clean, the operator calling on inspector before screwing in the adapter plug. The adapter plug is then screwed in, in the inspector's presence, and same must be screwed in so that the head will seat properly in the counterbore. A little vaseline mixed with gasoline is used as a lubricant.

Operation 12: Facing to Weight—The shell is examined to see that the face is smooth, to see that the radius of the fillet is correct, and is also carefully weighed to see that it comes within the limits of the weight requirements.

Operation 13: Stamp—The shells are carefully inspected to see that the proper stamping, consisting of 8-in. Howitzer—3, F & S, date of completion, trade-mark, heat number and serial numbers are stamped neatly and correctly.

Operation 14: Remove Adapter Plug—No inspection is necessary except to be sure that the operator does not damage the threads of either the shell or adapter plug in this operation.

Operation 15: Clean Shell—The shell body, especially the interior, is gone over carefully to see that shell is perfectly dry and clean.

Operation 16: Varnish—Special attention is given to this operation, as it is imperative that the coating of the varnish is absolutely smooth, free from cracks and that there is no varnish in either of the threads. The inspection can be well done with an electric light and a mirror.

Operation 17: Turn Copper Bands—The diameter and general shape, the width and depth of groove, the spacing of serrations and the shape of the band are carefully inspected by the use of gages provided. The finish according to sample must be maintained.

Preliminary and Final Inspection—The preliminary inspection consists of going over each shell body and adapter plug and ascertaining that all dimensions and conditions are according to the drawing and specifications. Gages are provided for this operation, but a scale is used in order to enable the checking of the weight of various parts, so that the weight will come out right in the end.

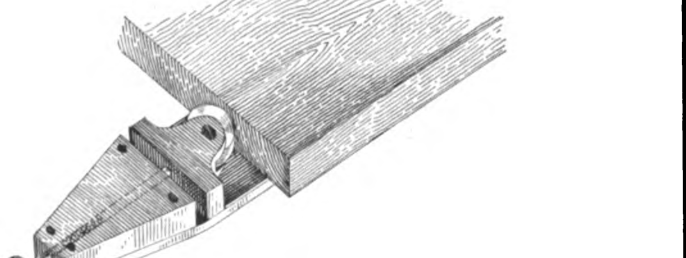
The final inspection consists of going over all inspection done prior to this operation and checking up each item to see that the shell is according to the accepted standards. The adapter-plug fit is carefully tried on each shell.

Stellite is now being used on the rough-turning, rough- and finish-boring and finish-turning operations with $\frac{1}{24}$-in. feed and 105 to 120 ft. per min. cutting speed, which makes a very satisfactory job. This alloy comes in three harnesses—Nos. 1, 2 and 3, No. 2 being found most desirable for this class of work.

Attachment for T-Squares

By J. M. Fitzgerald

The accompanying illustration shows an easily constructed and satisfactory attachment for small T-squares.



ATTACHMENT FOR SMALL T-SQUARES

Any desired tension may be obtained by means of the knurled screw, so that the board may be used at any angle and the square will stay wherever placed.

A Department of Economy*

By W. Rockwood Conover†

The organization of every large industry should include a department of economy. Even in the smaller factory some person should be definitely assigned to the work of investigating and controlling the expenditures on expense and investment accounts. The scope of this work is so broad that it does not receive adequate attention where it is divided and the responsibility assumed by busy officials or placed on the heads of manufacturing departments. The big industries and many municipal corporations are already recognizing the importance of maintaining a department specially devoted to the study and control of expense matters. Publicity is one of the most potent factors in overcoming waste and extravagance, either in public or private business, and the department of economy exerts a most valuable influence toward this end.

The economist must be a person of broad experience in his line of work. He must be a free lance in the factory, in order to pursue his duties with a good measure of success. It is his function to investigate conditions in any office or department, and in doing this he should have unrestricted authority to ask and insist upon the coöperation of the foreman or his assistants. All expense matters, whether relating to labor or material charges, come under his observation. A record of the organization of each department should be maintained for reference, and this record should be correct to date at all times. At the close of the month reports of the number of help of all classes working in each shop or office should be sent to the desk of the economist for inspection. These reports bear the signature of the foreman as certification that they are correct. All requests to supply additional expense help should also be sent to the department of economy for approval before the help is employed. By comparing the number of expense employees with the number of productive employees working each month the economist is able to judge whether the foreman is justified in asking for additional labor in the expense classes. Productive conditions, such as new orders or rush business, should receive his consideration in making decisions. The regular reports of the production department relating to apparatus on schedule, shipments, unfilled orders and new business are also of assistance to him in his work.

One of the functions of the economist's office is to issue to the head of each department a weekly budget statement of expenditures on the various expense shop orders, including manufacturing expenses and maintenance of property items. On this sheet is shown the budget allowance per week against each separate account for operating expenses. These statements are carefully scrutinized, the expenditures for the different classes of labor compared with the budget allowance and checked, whenever necessary, with the organization record showing the number of help employed in any given classification under investigation. These sheets are compiled from the payroll records immediately on the close of the roll, which enables a prompt investigation to be made while the cause for any increase in expenditure is still fresh in the foreman's mind. This system of furnishing information to department heads and making criticisms week by week exerts a wholesome influence in establishing uniform efforts toward economy and permanent methods of control.

Reports of all expense materials, such as miscellaneous shop and office supplies, lubricants, fuel oil, gas, etc., consumed in the various departments should be sent each month by the central storekeeper to the department of economy for inspection and criticism. The amounts used are in turn sent out in a detail report to each foreman, so that he may be posted on these expenditures in his individual shop. The issuing of these reports regularly has a marked effect in preventing extravagance and waste. Constant investigation by the economist also exerts a helpful influence in teaching the head of each department to keep a close watch upon these items. It opens the way for devising means of controlling the consumption more adequately than is feasible where the matter is left in the hands of the foreman.

Machinery and tool-repair accounts, miscellaneous repairs and all expenditures on maintenance of property accounts are items that should receive the attention of the economist. In like manner all purchases of office furniture, office supplies and forms, miscellaneous shop equipment and purchases in general of a special or expense nature require the consistent attention of some person equipped with the knowledge and experience to pass upon these items.

In the small factory the superintendent may find time to look into these matters with some measure of success, but in the big, modern industry his time is largely taken up with business of an executive nature, which prevents the investigation of a very large number of details usually considered of lesser importance and which are usually left to the heads of individual departments, with the result that many such items receive only indifferent attention or no attention at all. The field for economic work in these large plants is practically without limit, and the organization of such work on a systematic basis of continued, efficient effort is worthy the manager's serious consideration as a profitable feature of business.

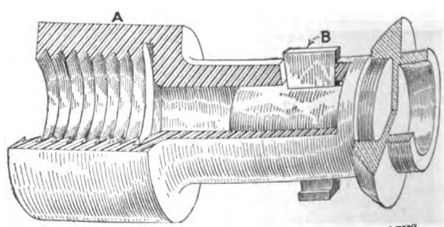
Simple Chuck for Machining Shrapnel Noses

By Fred Fruhner

The illustration shows a simple chuck for turning and threading brass noses for shrapnel shells. The chuck consists of a body *A*, which screws on the spindle. The other end is threaded to go into the work. The shank has a taper slot *B* in it, so that when the job is put on, the key is loose. By driving the wedge down, the work is ready for operation.



CHUCK FOR MACHINING SHRAPNEL NOSES

Successful Suggestion Plan

By W. J. Tewksbury*

SYNOPSIS—The reason why so many suggestion plans fail is because they are allowed to die a lingering death. Enormous energy is put into them at first, but the interest in them is allowed to dwindle. The suggestion plan described herewith is a success because the management put sufficient energy into the project to keep it alive.

Various kinds of suggestion plans have been tried and condemned as, partial, if not complete, failures by a great many manufacturing concerns in the past. I have had considerable experience during the past 15 years with a number of schemes which failed and others which at the start showed promise, but later had to be dropped through lack of satisfactory results obtained or lack of interest generally.

Some four or five years ago, however, a new attempt was made, no scheme of this character having ever previously been tried out by our company. Notices were

SUGGESTIONS

Every EMPLOYEE of this company is invited to make SUGGESTIONS.

We want your CO-OPERATION in our work.

We welcome CRITICISM.

YOU are on the job. YOU are in a position to know what is needed, in many cases, BETTER than any one else.

USE the suggestion BLANKS. Seal the SUGGESTION in the addressed envelope and place it in the suggestion BOX at the EAST or WEST entrance, or send it through the MAIL (Local service).

Each suggestion will receive my personal ATTENTION.

If you don't THINK the reason given for rejecting a suggestion is a good one, take the question up PERSONALLY with the undersigned.

If you do not receive an ACKNOWLEDGMENT for each suggestion sent in, NOTIFY the undersigned.

DO NOT expect to be advised as to the REJECTION or ACCEPTANCE of your suggestion at once. It takes TIME to investigate and to SECURE the facts before passing on its MERITS.

W. J. TEWKSBURY,
Factory Superintendent

FIG. 1. NOTICE SOLICITING SUGGESTIONS

printed and posted on the bulletin boards throughout the factory, and a quantity of printed suggestion blanks was supplied to each department. The notices asked employees to make suggestions at will, and for a while quite a number were received, many of which were worth while, saving money, improving quality, etc.; but after a number of months they began to drop off. A few of the foremen, however, took considerable pride in the matter from the first and were so enthusiastic in their efforts that it occurred to me that the solution of the problem was not so difficult a one as it appeared. The idea worked out in detail in the following manner:

First, printed cards, as in Fig. 1, were neatly framed and posted throughout the factory, most of them being placed above the drinking fountains, where they would be seen by all employees. Directly below or to one side of the framed notice was fastened a suitable box, on

SUGGESTIONS

2366

Date 8-17-15

I suggest that in packing the connector shelves, that the brace which holds down the shelf be bolted in and the lid be fastened on with screws, by adopting this method the boxes will not be destroyed and they can be returned. These boxes cost $1.97 each. We will require 600 boxes on the St. Paul alone.

The Department designated shall secure above information and return to Factory Superintendent.

SUGGESTION { ~~Rejected~~ Approved

W. J. Tewksbury,
FACTORY SUPERINTENDENT.

ADDITIONAL INFORMATION OR SKETCHES CAN BE MADE ON THE BACK OF THE SHEET.

FIG. 2. FILLED-IN SUGGESTION BLANK

the front of which was lettered the word "Suggestions." In this box was put a supply of suggestion blanks similar to the filled-in blank in Fig. 2, inclosed in addressed envelopes like Fig. 3. An employee can take a blank without being required to go to the foreman's desk and ask for a blank and envelope. The average workman is found to be disinclined to do anything which in his estimation is likely to get him in wrong with the man to whom he reports. Human nature will out, and in some cases undoubtedly a jealous foreman afraid of his job might take offense at something some one of his employees suggested.

To eliminate so far as possible any chance for a feeling of this nature and to make it easier for the employee to do what he might like to do, we placed these addressed envelopes containing suggestion blanks as specified. Another change that is vital to the success of the plan now in operation consists in requiring each

*Factory Superintendent, Automatic Electric Co., Chicago, Ill.

foreman to send in a report once a week to the factory superintendent. He can make as many suggestions as he sees fit; but in case he has no idea to suggest during the week, he must before 9 a.m. of the following Tuesday send in a suggestion blank on which he writes, "No suggestion for this week," and signs his name thereto. Any foreman failing to send in at least one bonafide suggestion or a blank with the foregoing remark during the week receives at once a copy of a form memorandum, Fig. 4. A factory superintendent's instruction No. 64, dated Apr. 20, 1912, had already been sent to each department, outlining the proposition in detail, Fig. 5.

W. J. TEWKSBURY
Factory Superintendent,
DEPT. 51

FIG. 3. THE ENVELOPE

This one requirement can be said to have contributed more to the success of our plan than any other one thing.

Pride entered into the matter. A foreman, realizing that a report must be made, disliked the idea of sending in a blank with a signed statement to the effect that he could think of nothing to improve conditions in any way, shape or form in his own department or anywhere else. He well knew that this department was far from perfect, and he know that I also was aware of it, with the result that the foreman began to think. Instead of taking things for granted, he began to use his head in a new manner possibly. He began to look for ideas, and in seeking for something worth while he discovered many cases that called for investigation and improvement. He found this layout in error, a blueprint incorrect, a tool or fixture so designed as to interfere with the operator's being able to turn out the maximum output in the minimum time. He discovered that he was possibly doing work that need not be done or that could be handled in another department at a lower cost and also save a transfer. His reserve force of brain power was brought into active use and developed. He became a more forceful executive, looking at the world and at his work in particular from a different angle, and this example had its effect. As a result, thinking

Your attention is called to Supt. Inst. #64 which specifies that:-

"All Shop Foremen shall make a suggestion report at least once a week to the Shop Superintendent on F-248."

"If there are no suggestions to be made, they shall send in a report in the same manner marking it "no report" and sign same."

Your report for week ending__________has not been received. Please forward same at once, and in the future arrange so that this report will be sent in and received by Dept. #51 not later than 3 o'clock Monday of each week.

____

FIG. 4. A GENTLE REMINDER

became more and more apparent, others became infected with the same desire and the plan became a success.

Of course, all was not accomplished in a day, a week or a month. Conditions changed gradually and were assisted by various schemes all working to one end, such as blotters, Figs. 6 and 7, and time cards, Fig. 8. The blotters are distributed to the office staff, foremen, engineers and draftsmen, while the daily time card is used by every factory employee for recording his time.

Lead pencils on which were stamped the company's name and the additional words, "Suggestions Wanted," were purchased and acted as a constant reminder to all employees who used pencils. In each department we placed blue or brown prints mounted on heavy cardboard and changed monthly. Problems for the month appear on this sheet and also a calendar for the month. Figs. 9, 10 and 11 are samples of the sheets mentioned. By selecting each month a new subject for the problem, such as time, thrift, save, efficiency, scheduling, trucking,

Factory Supt's Inst. #64
April 20th, 1912.

SUGGESTION REPORTS

All Shop Foremen shall make a suggestion report at least once a week to the Factory Supt. on Form F-248.

If there are no suggestions to be made they shall send in a report in the same manner marking it "no report" and sign name.

Suggestions, such as improvements in methods of manufacturing, tools, equipment, increase of efficiency, saving in the management of departments, should be reported. The reports are to be sent to the Factory Supt. (Dept. #51) in a sealed envelope, and an investigation will be made under personal instructions from his office.

Suggestion forms should specify the piece number or drawing number in each case, and explain briefly and precisely the suggestion to be considered. If a sketch is required to give the necessary information the same can be made on the reverse side of the suggestion report Form F-248.

These suggestion report forms are to be used by any employee desiring same. Forms shall be kept in a box in each department for use of employees desiring them.

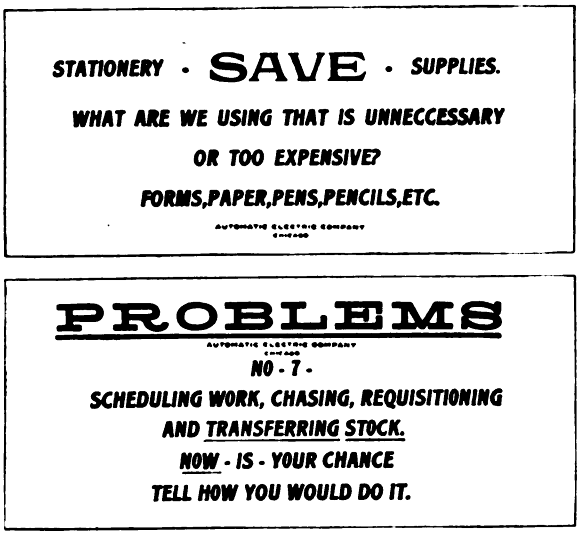
W. J. Tewksbury,
WJT/S. FACTORY SUPERINTENDENT.

FIG. 5. OUTLINE OF SYSTEM SENT TO SHOP FOREMEN

rate setting, etc., interest is maintained, and new lines of thought are developed. In addition to the blueprint problem and calendar referred to, it was my practice to send out a letter to all department heads, foremen included, in which the problem was discussed at some length.

About a year ago we began issuing monthly bulletins, printing a sufficient number so that each employee interested received one. In addition to this monthly letter a lot of local news appears in the bulletin, "doings," and has gone a great way in creating further interest in this plan, particularly with those who previously had given the matter but a small amount of consideration. The results of our first year's experience were not altogether satisfactory, and we made changes until we have what may be considered a fairly successful "Suggestion Plan," even if passed on by a biased judge.

The management realized before the end of the second year that the plan was working along the right lines, and a banquet was arranged for. Employees who had to their credit an approved suggestion during the year were given a ticket to the banquet and came as guests of the company; all other employees were required to pay. In addition certain employees, according to the value of suggestions approved, were presented by the management with gold, silver and bronze watch fobs, suitably engraved to show that they were presented by the company for valuable suggestions during 1913. The following year, 1914, was more successful as a record producer. In 1912 there had been but 41 employees, who made a total of 302 suggestions, of which we approved 147. In 1913, from 137 men and women came a total of 714 suggestions, of which there were 481 approved. In 1914 the 146 employees made 1,314 suggestions, and we approved 613 as being worth while. In 1915, the total number of employees being considerably reduced on account of business depression, there were but 135 who sent in suggestions. However, the total number made increased to 2,345, of which 1,189



FIGS. 6 AND 7. TWO FORMS OF BLOTTERS

were approved, or more than 50 per cent. In 1914 we celebrated the conclusion of the year's work by a banquet, at which we presented to those who had distinguished themselves various tokens of the company's appreciation.

The best record was made during that year by the foreman of our screw-machine department, and he received a 21-jewel gold watch. Others received 17- and 15-jewel gold watches, diamond-set knives, gold, silver and bronze watch fobs, etc. The value of the total approved suggestions made determined the class in which the individual was placed, and the value of the article presented was in accordance with the value of the suggestions received from that particular individual. There were seven classes or divisions that year, the seventh being those who had at least one approved suggestion to their credit and were therefore invited to be the guests of the company at the banquet.

In 1915 the same arrangement was made, with the addition of a dance after the banquet. The tokens for 1915 consisted of all the articles used in previous years, with the addition of three classes of rings. In class No. 1 the rings were set with ten diamonds, one in each of the finger holes of the dial of the automatic phone, as on each ring was engraved a facsimile of the dial. Class No. 2 rings were set with one diamond, and class No. 3 were plain, all, however, being engraved with the dial, as in case of classes No. 1 and No. 2. The banquet was attended by 700 of our employees, which was just double the number attending the first banquet in 1913. We have received suggestions from office boys, clerks and stenographers. Everybody is thinking, and the fever is catching.

We bar all employees above the rank of foreman from competing, but do not of course bar them from making

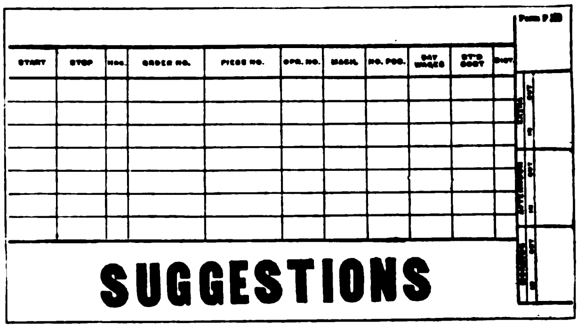


FIG. 8. THE TIME CARD

suggestions. The greatest saving which any one suggestion has made during a single year is $6,700. We have had several instances where the total value of all the suggestions made during the year by one employee reached $1,000 or more. There have been hundreds of approved suggestions on which no money value could be figured, and many cases where adopting the suggestion has meant a higher manufacturing cost and the expenditure of a considerable sum of money for tools,

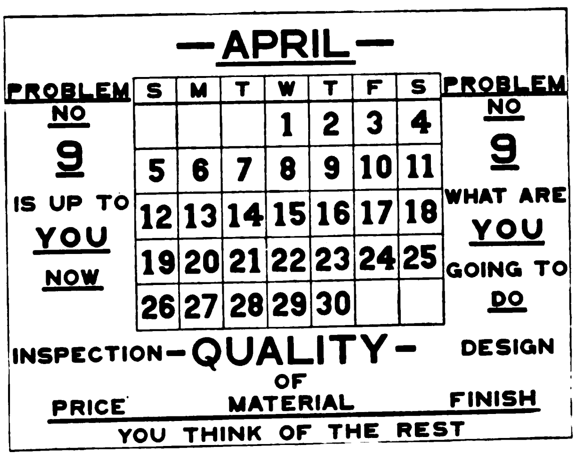

FIG. 9. EXAMPLE OF MONTHLY CALENDAR

fixtures, etc. We encourage safety-first suggestions, and they are frequently received.

I recall that one boy in particular, one of our mail carriers whose duties took him all over the plant, made 14 suggestions during the year 1915, and 8 of them were approved. They were all worth while, although none of them saved any great amount of money, nearly all being

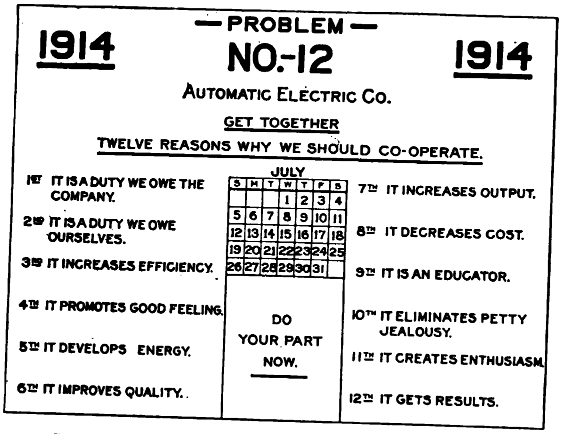

FIG. 10. EXAMPLE OF MONTHLY CALENDAR

along the line of efficiency. For example: In the office in which this boy works there are about a dozen overhead 250-watt lights, one for each 16-ft. square. Each one is controlled from a switchboard located at one end of the office. One of the errand boy's duties is to switch off lights when not needed or to switch them on at request, and it was noticed that each time a new boy was hired he had to learn which button to snap. The suggestion was to put up a plate designating the buttons and thus avoid delay and annoyance. I simply cite this case to show what a boy will notice and comment on when the whole force is more or less interested. Each suggestion when received is given a number and immediately acknowledged on the form, Fig. 12; when approved or rejected, the person making the suggestion is immediately advised by a special form.

Our suggestion year begins on Dec. 1, and since that date last year we have received 854 suggestions. There have been approved so far this year 297 suggestions. A number of these, however, were suggestions made last year, as it sometimes takes several weeks and often months before a suggestion is finally approved or rejected. There are several reasons for this. Suggestions of most importance are acted upon first; and frequently a suggestion may require experimental work and the approval of the engineering department, as well as various other departments, in some cases, all of which takes considerable time before justifying a final decision.

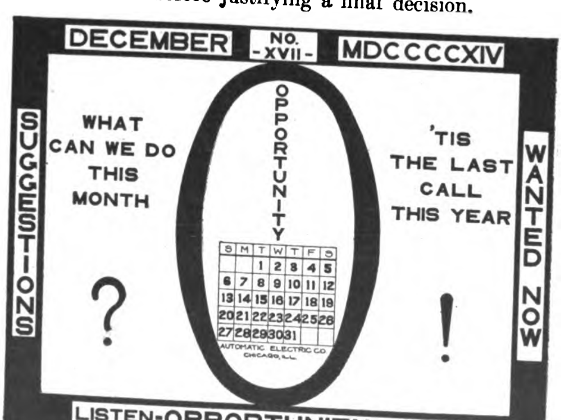

FIG. 11. EXAMPLE OF MONTHLY CALENDAR

Another feature in connection with our plan is that each suggestion made is sent to me personally in a sealed envelope, and I personally approve or reject it. True, I do not do the actual work of investigating the value of each suggestion made or estimate tool costs, savings, etc., but I do finally pass on the merits of the point involved. Each suggestion being acknowledged the day it is received and notice being sent out the moment a decision is reached are of considerable importance in maintaining a satisfied state of mind in the employee. In advising an employee that his or her suggestion has been rejected the cause of rejection is always given, and I repeatedly call attention in "Doings" to the fact that in case an employee has reason to believe that an error has been made in the decision he shall make it a point to see me personally and explain his views and reasons.

Assuring a Square Deal

Not allowing the general foreman, master mechanic or the head of any division outranking a foreman to compete reduces the chance of a possible suspicion arising that some foreman's thunder has been stolen. Also, having employees and foremen send their suggestions to

Mr.______________ Dept.________.

We acknowledge receipt of your suggestion of ________

regarding ______________________________

This suggestion will be given due consideration and a memorandum of its disposition will be sent you as soon as possible.

W. J. Tewksbury,

FACTORY SUPERINTENDENT.

FIG. 12. ACKNOWLEDGMENT FORM

me direct eliminates another chance for complications. By playing the game square, giving all an honest deal, the confidence of the employee is secured and ultimate success is assured.

The banquets, the public presentation of tokens in the presence of all one's fellow employees, personal pride, the success of others—all tend to create interest and enthusiasm, which to my mind can be maintained indefinitely just so long as everyone is treated honestly and justly. The success we have had cannot possibly be due to any peculiar condition in our plant. Others can secure the same results if the proper methods are adopted and used. Many are undoubtedly having equal success by means of other plans than ours, but the fact remains that what we have we have; and what has been done is being done here with increasing success each year in spite of the failures that have been experienced with other systems by other firms.

Resharpening Old Files

By Cecil H. Strupe

To resharpen an old file, heat it in a furnace or forge until a good scale appears uniformly over its surface and harden it at the proper temperature. Then take a good stiff file brush and clean the file thoroughly. You will find that the scale comes off readily, leaving the file with fairly good cutting qualities. The only trouble with this manner of sharpening a file is that it can be repeated only a few times.

Letters from Practical Men

Storage of Grinding Wheels

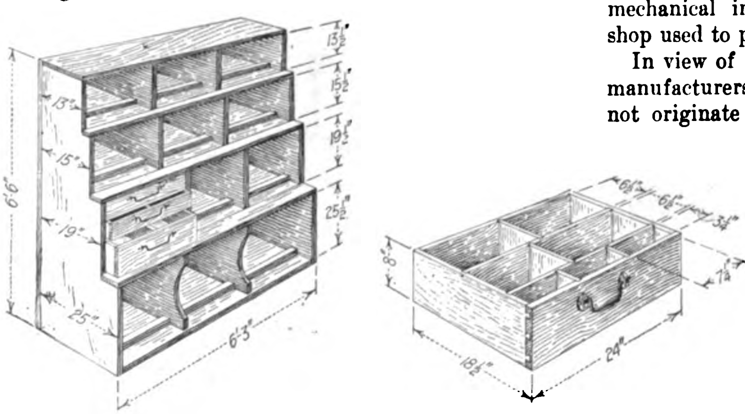
Grinding enters so largely into modern manufacturing methods today that the safe storage of the grinding wheel demands attention. The wheels usually vary largely as to size, and quite frequently wheels of the same general dimensions will vary considerably as to both grain and grade.

If the wheels are piled on top of one another the constant handling to which they will be subjected may result in damage; further, the identification tab is sure to get damaged or lost. Undoubtedly the best way to store grinding wheels is to stand them on a wooden rack so that any one wheel may be reached without interfering with any other wheel.

Apart from the larger wheels that will stand in a rack there are many kinds of small wheels required both for internal work and for general toolroom requirements. If an open rack is used for the large wheels, the small ones may be kept in boxes on the rack; but where much grinding is done, the best way to store the wheels, in the opinion of the writer, is to have a special rack or cabinet for the purpose. The one shown in Fig. 1 has for some years given satisfaction in a large plant where many sizes of wheels are used.

The general dimensions of the rack are given on the illustration, and it will be seen that the inside dimensions are such as to accommodate wheels of 24-, 18-, 14- and 12-in. diameter respectively. A strip across each of the various pockets effectually prevents any wheel from running forward.

It will be noticed that three drawers are provided for storing the smaller wheels. These drawers are 24 in.



FIGS. 1 AND 2. STORAGE CABINET FOR ABRASIVE WHEELS

long, 18½ in. from back to front and 8, 5 and 4 in. deep respectively. The two lower drawers have thin longitudinal spacers, so that 6- and 4-in. wheels stand edgewise and close together, thus giving maximum storage with accessibility. The lowest of the three drawers is shown in Fig. 2, with dimensions as used, but these of course must be varied to suit the wheels to be stored. The top drawer should be divided in such a manner that by means of adjustable spacers a variety of pockets may be formed for storing small wheels for internal grinding.

By putting the grade and grain of each of the larger wheels on its periphery with a stencil it is possible with such a rack to extract at once any wheel desired. Apart from this the stock available is seen at a glance, and consequently there is less risk of running out of sizes accidentally.

Made of white wood, generally about 1¼ in. thick, the cabinet presents a solid appearance, takes up very little space, considering its capacity, and will add to the efficiency of any tool-storage service.

Guildford, England. WALTER G. GROOCOCK.

Future of the Public-School Machine Shop

This is not written in the nature of a prophecy, but to set forth what, to the writer, seems to be the logical outcome of the industrial-education movement, if the schools are to progress and do the work which was expected of them.

My understanding of the trade school (and I confine myself to the machine-shop department) is that it is intended to keep up the supply of mechanics. The apprentice system in most shops is dead. Indeed, in most shops they will not even consider taking an apprentice. The largest number of their so-called machinists are simply men who turn a wheel or pull a lever, merely operators. Is this the kind of stock that will produce mechanics, where the son will follow in the father's footsteps with pride? There is nothing there that will tend to produce mechanical ingenuity or genius, such as the old-time shop used to produce. In fact, the contrary is true.

In view of this condition, then, some of our far-seeing manufacturers began talking trade schools. The idea did not originate among the teaching profession. It came from hard-headed, shrewd business men, who as they saw the gradual passing of the apprentice system, began to look around for a substitute and evolved the trade school. But having created the idea, they were content to turn it over to the educator. Now that the schools have passed their infancy, so to speak, and are beginning to arrive at the interesting stage where they take on character and individuality, the manufacturer is getting interested again and can begin to see in them something besides a plaything. With this added interest will come a desire to step in and shape the policies of the school, so that the graduate will fit into the machine shop or toolroom with the least possible adjustment. In other words, our school shop must differ in no way from the commercial shop, as we must always consider the kind of a place the boy will work in.

I expect to see the school shop commercialized. It will have to start manufacturing on a commercial scale some article or tool that will give sufficient general work in the shop and toolroom to develop all-around machinists, if I may use an expression to which no two people give the same meaning. It may even monopolize the market for its product by making the price below competition, and it can do this because it has no labor expense.

Such a course of procedure would be bound to hurt somebody, but this must be foreseen and taken care of. The thing must be done, even if it does hurt a few individuals, because it is a question of the greatest good for the largest number of people.

A possible solution might be to have some of the manufacturers' associations coöperate and decide what particular line of work should be undertaken. The school could then go ahead and take over that line, as private land is taken by the right of eminent domain and compensation paid to the parties damaged.

But by whatever method the result is obtained, I feel that some such action should be taken and these school shops put on a self-supporting basis. For surely so much labor should at least be made to support itself instead of only partly doing so, as at the present time. In order to preserve the commercial standard of the product, it may be necessary to employ some experienced workmen in addition to the instructors.

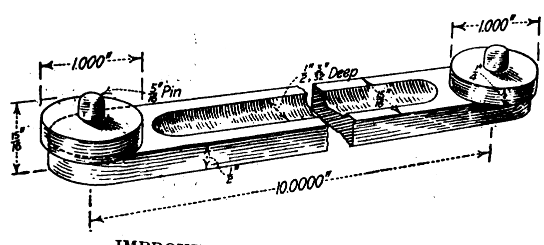
There will always be the danger of commercializing the school to too great an extent; but I believe that, with the proper mixture of shopmen and schoolmen on the governing board, the proper balance can be preserved.

Westfield, Mass. BURTON A. PRINCE.

Improved Type of Sine Bar

Those of us who set sine bars know that frequently one can spend a considerable amount of time in getting the bar just right. It was to save this time that the sine bar shown was devised.

The bar is $\frac{15}{16}$ in. wide, $\frac{1}{2}$ in. thick and $10\frac{15}{16}$ in. long. It has two holes through it at the ends, these holes being exactly 10 in. apart, center distance, and $\frac{5}{16}$ in. in diameter. Pins are snugly fitted to the holes, and on these



IMPROVED TYPE OF SINE BAR

pins are two 1-in. Brown & Sharpe micrometer test gages, such as come with all 1 to 2 in. micrometers.

It will be noticed that the disks project beyond the bar. If the bar is clamped against an angle plate, the lower end does not rest upon the surface plate, but the lower part of the disk touches the plate. If conditions are such that the bar cannot extend down to the base plate, the lower disk can rest on a parallel.

All that remains to be done to establish the angle with the bar is to multiply the natural sine of the angle by the center distance between the disks—10 in.—and set a vernier height gage to this dimension, using the side of the beam marked "Outside." Rest one disk of the bar on the surface plate or parallel and swing the bar so that the other disk just touches the under side of the projecting finger of the height gage—that is, standing on the surface plate or parallel, as the case may be. This establishes the angle. If an angle is being checked, the reverse of the foregoing is the correct procedure.

It will be seen that this bar can be set in a minimum amount of time, that only one "feel" is involved and that adding one diameter of a disk is eliminated.

New York City. WESLEY E. MCARDELL.

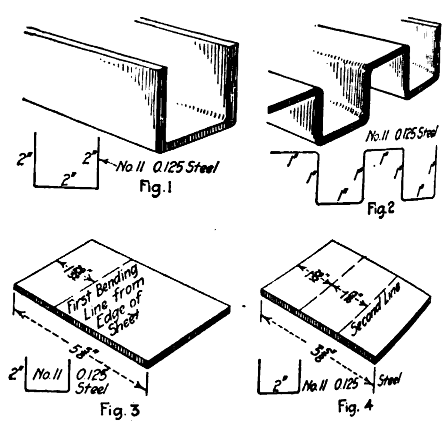
Sheet-Metal Data for Making Steel Furniture

The accompanying illustration shows data and tables which have been developed for laying out and bending sheet metal in the manufacture of steel furniture. Theoretical accuracy is not contemplated. These tables and rules are intended to be used by the practical mechanic in the process of actual production.

The rule for determining the development length or cutting size of a piece to be bent, where outside measurements are given, is as follows: From the length of all dimensions subtract $1\frac{1}{2}$ times the thickness of the metal to be used for each right-angle bend.

FOR DETAILING SHEET METAL

Gage No.	Decimals of an Inch	¾ Times Thickness of Material, In.	1½ Times Thickness of Material, In.	Gage No.	Decimals of an Inch	¾ Times Thickness of Material, In.	1½ Times Thickness of Material, In.
1	0.281	7/32	27/64	14	0.078	1/16	7/64
2	0.265	13/64	25/64	15	0.073	1/16	7/64
3	0.250	3/16	3/8	16	0.062	3/64	3/32
4	0.234	11/64	23/64	17	0.056	3/64	3/32
5	0.218	5/32	21/64	18	0.050	3/64	5/64
6	0.203	5/32	5/16	19	0.043	1/32	1/16
7	0.187	9/64	9/32	20	0.037	1/32	1/16
8	0.171	1/8	1/4	21	0.034	1/32	1/16
9	0.156	7/64	15/64	22	0.031	1/32	3/64
10	0.141	7/64	7/32	23	0.028	1/64	3/64
11	0.125	3/32	3/16	24	0.025	1/64	3/64
12	0.109	5/64	11/64	25	0.021	1/64	1/32
13	0.093	5/64	9/64	26	0.018	1/64	1/32



FORMS OF BENDS FOR STEEL FURNITURE

Example No. 1—$2 + 2 + 2 = 6$ in.; $1\frac{1}{2}$ times the thickness of No. 11 steel equals $\frac{3}{16}$ in. for each bend. For two bends, $2 \times \frac{3}{16} = \frac{3}{8}$ in.; $6 - \frac{3}{8} = 5\frac{5}{8}$ in., the cutting size of the material.

Example No. 2—$1 + 1 + 1\frac{1}{4} + 1 + 1 + 1 + 1 + 1 = 8\frac{1}{4}$ in.; $1\frac{1}{2}$ times the thickness of No. 11 steel equals $\frac{3}{16}$ in. For seven bends, $7 \times \frac{3}{16} = {}^{21}/_{16} = 1\frac{5}{16}$ in.; $8\frac{1}{4} - 1\frac{5}{16} = 6\frac{15}{16}$ in., the cutting size of the material.

The rule for locating the first bending line from the end of the sheet follows: Subtract $\frac{3}{4}$ times the thickness of the metal used from the measurement given in detail in example No. 3. The answer will be the distance of the first bending line from the edge of the sheet.

Example No. 3—First dimensions given, 2 in; thickness of No. 11 gage = $\frac{1}{8}$ in.; $\frac{3}{4}$ times the thickness of No. 11 gage equals $\frac{3}{32}$ in.; $2 - \frac{3}{32} = 1\frac{29}{32}$ in., which is the distance of the first line from the end of the sheet.

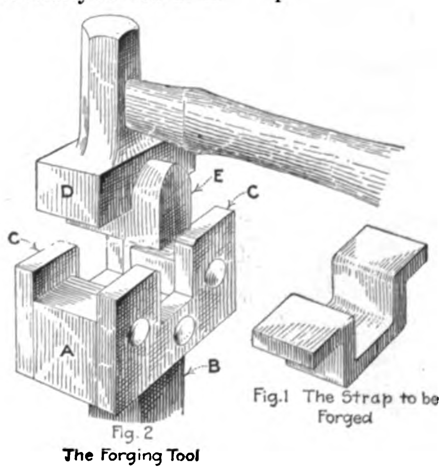
The rule for locating the second bending line from the first bending line is as follows: Subtract $1\frac{1}{2}$ times the thickness of the metal used from the outside measurement given in detail. The answer will be the distance of the second bending line from the first bending line. To lay out three or more bends, use the same rule as for the second bend. WILLIAM L. WEBER.

Two Rivers, Wis.

Forging Straps by Hand

In this time of stress many shops have to do the best they can with limited appliances. This is particularly true of blacksmith shops, and many interesting tools have been improvised to meet the present rush.

When repetition work is to be done, the modern smith too often thinks that the drop hammer and the press provide the only solution. In so thinking they are of course overlooking the fact that the smiths of old did excellent work with anvil tools, which in some classes of work are nearly as fast as the drop hammer or the press.



TOOLS FOR FORGING STRAPS BY HAND

The following is a case in point: A shop busy on some general service wagons for the army required about 1,000 straps, as illustrated in Fig. 1. Drop or press forgings being out of the question, a smith was put on to make the straps by hand. His progress was so slow that his foreman was in despair. The writer, visiting the shop at this time, was told the difficulty and suggested a set of anvil tools, Fig. 2.

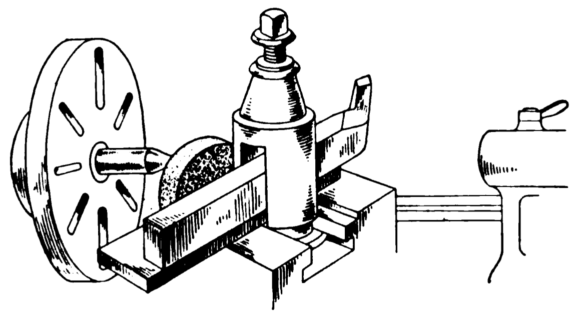
Another smith made a set of these tools from a sketch and with them turned out 900 staples complete in 12 hr. Considering that this was his first batch, the time was good, but undoubtedly he could do 80 per hr. with ease in any subsequent lot.

The illustration requires little explanation. The bottom tool *A* is forged square at *B* to fit the anvil. Riveted on the side are two guide plates *C*, which serve to guide both the steel to be worked on and the top tool *D*. The lugs *E* on the top tool are best made solid, as drawn, but they could of course be riveted on. The method of operation is obvious and needs no description. H. KING.

Guildford, England.

Truing a Lathe Center Without a Center Grinder

Before the modern lathe-center grinder came into use, the general method was to anneal the center and then turn it up. To avoid this annealing, rough the center down



TRUING A LATHE CENTER

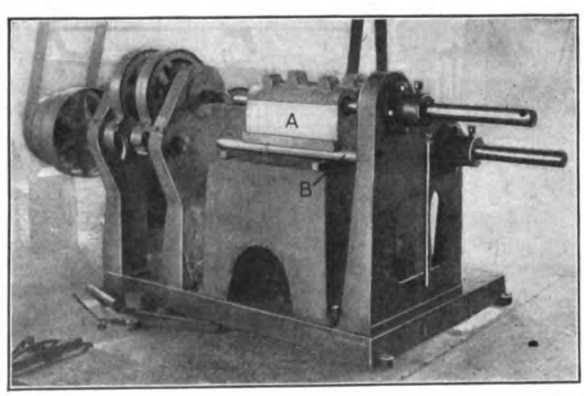
to gage by hand on an emery wheel, then stick it into the live spindle. Prop a small worn-down emery wheel about 2 in. in diameter against a tool in the tool post at the proper angle and press it against the center running at a high speed.

The sketch shows a $\frac{1}{8}$-in. piece of flat steel clamped under the tool and supporting the emery wheel.

Stockton, Calif. M. JACKER.

Special Boring Machine

Having a number of large shaft bearings to bore in dough-mixer frames, we decided to build a special duplex boring machine, the centers on the boring bars being the



A SPECIAL BORING MACHINE

same as on the frames to be bored. The two frames were set in an upright position and bored through with a tool fixed at each hole. Afterward a shell reamer was passed through

The operation is so simple that it requires only about an hour's time to bore and ream four 3-in. holes instead of nearly a day for each frame in the old way, when they were bored on a large drill press.

In the illustration at *A* is another job that we bored on this same machine. Two grooves were planed parallel with the holes to be bored. The piece was 18 in. long, but the holes to be bored were only 5 in. on each end, the center being chambered.

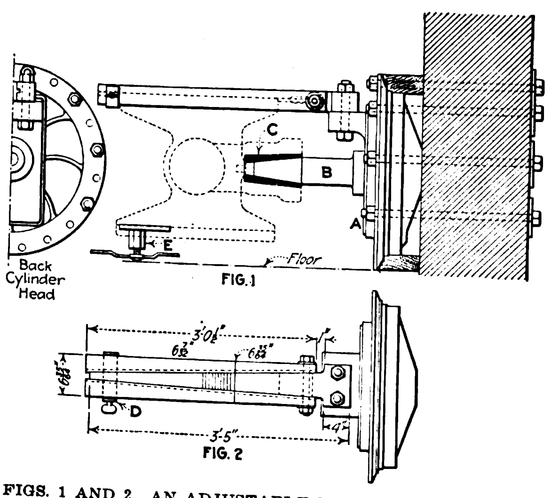
As the boring bars could travel only 14 in., we set the part *A* on two 2-in. shafts *B* to act as "ways." After going through the first end of the holes, we released the clamps and pushed the work ahead about 6 in., then clamped it down, ready for the other end of the bore. As there were two sets of holes to bore with centers 6 in. apart and as the boring bars were 16½ in. apart, only one bar could be used; but as the holes were central with the grooves, it was only necessary to set the ways central with the boring bar and turn the job end for end to get both sets of holes bored.

PETER MOTTA.

Joliet, Ill.

Babbitting Solid Crossheads

The illustrations show a method of babbitting solid crossheads of locomotives. First, a back cylinder head is bolted to the wall of the shop or one of the columns, as at *A*, Fig. 1. In using, a wooden distance piece, as shown, is put in the cylinder-head counterbore, next the large end of the babbitting mandrel *B*. Then the adjustable bushing *C*, which is in three parts held together by a spring band, is put in the piston-rod end of the crosshead and this is put on the mandrel *B*. The upper



FIGS. 1 AND 2. AN ADJUSTABLE BABBITTING FIXTURE

piece, representing a guide and adjustable as to width, is put in place and set to proper width to suit guides of locomotive to which the crosshead belongs. The series of graduations in Fig. 2 shows the range of sizes from $6\frac{7}{32}$ to $6^{35}/_{64}$ in. The clamp *D*, Fig. 2, is for holding the forms in place, while the small jack-screw *E*, Fig. 1, is for raising or lowering the end of the crosshead as may seem necessary. The babbitt is then poured.

Another mold for babbitting solid crossheads and those having shoes is shown in Fig. 3. The spindle *A* is put through the crosshead, the large tapered part being made to fit the bore at the piston-rod end. Then the sleeve *B* is put in from the opposite end over the spindle *A*, the square tapered part *C* entering where the front end of the main rod goes in. Next the end plate *D* is put on and tightened, then plate *E*, both of these plates having eye-bolts shown, and cross-end plates *F* are put in place and tightened by the long through bolts. The top and

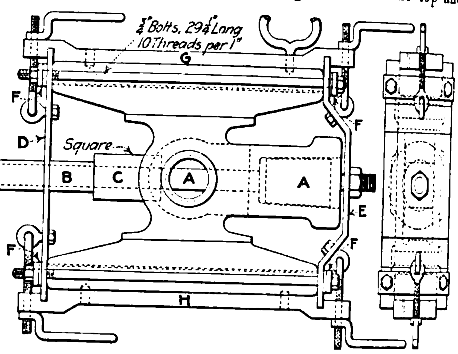


FIG. 3. ANOTHER TYPE OF BABBITTING FIXTURE

bottom forms are put in place and the eye-bolts swung into the slotted ends and tightened. By using gages of different thicknesses, the distance between the mold and the crosshead shoe can be made to suit.

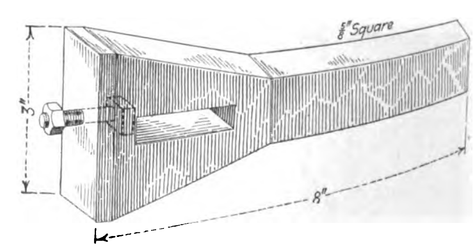
The large eye-bolts are for the purpose of picking up the mold after pouring, as it gets very hot. The molds *G* and *H* are usually made of three different thicknesses to suit requirements and are $\frac{1}{32}$ in. less in thickness at bottom than at top to facilitate easy removal. When assembled, the entire rig can be set on a small horse or stand, and after one side is poured it can be easily swung over to pour the other side.

Renovo, Penn.

JOSEPH K. LONG.

Gated Pattern Holder

The illustration shows a holder for gated patterns. It is a casting 8 in. long, with a ⅝-in. square shank and an opening large enough to take the head of a ¼-in. bolt.



GATED PATTERN HOLDER

The pattern gate is held to the holder by the bolt. The shank of the holder is held in a vise at any desired angle. The method of inserting the bolt makes it readily replaceable when it becomes worn.

A. E. HOLADAY.

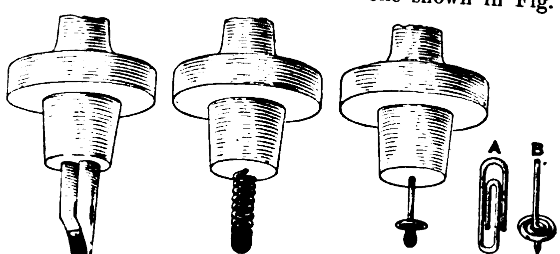
Naugatuck, Conn.

The British Board of Trade announces that the prohibition on the importation of hardware does not apply to the following articles: Awl blades, bayonets, bullet molds, caps for cartridge making, cartridges, cases, hammers, horse clippers, jacks, small and screw percussion cap shells, pliers, pulleys and blocks, scythes and sickles, shears, spanners, tools for carpenters, coopers, masons or shipwrights, trenching struts and brass or copper tubes.

Discussion of Previous Question

Helpful Drafting-Room Kink

The quill shown in the illustration by W. J. Gaffke on page 188 is rather old. The draftsman, however, sometimes has no means of getting the tin to make such a device. Under such conditions the one shown in Fig. 1



FIGS. 1 TO 3. HELPFUL DRAFTING-ROOM KINKS

may be used. Two common pen points are inserted, as shown, about $\frac{1}{16}$ in. apart.

In Fig. 2 is shown a quill that can be found around the shop all ready made, and Fig. 3 shows a contrivance that is useful when the ink in the bottle is low. Bend a paper clip *A* as shown at *B*, insert it in the quill, and the ink can be obtained at the very bottom of the bottle.

Chester Park, L. I. M. CARRY.

Built-Up Circular Forming Tool

I don't like to be "kicking" all the time, but in relation to Mr. Bennett's article describing a built-up forming tool, *American Machinist*, Vol. 44, page 560, there are a few things about forming tools that he neglected to say.

We have been using forming tools on National Acme, Gridley and Cleveland automatics for years and at very high speed. We work to a limit of 0.002 in. and use up, almost entirely, all our forming tools. My personal experience leads me to believe that a built-up forming tool would be highly undesirable and impracticable, primarily because of the rivets and secondarily because of the difficulty of true assembling.

A forming tool, on account of the stresses imposed upon it in service, must be of solid construction and rigid. Now a tool such as that described by Mr. Bennett, while it may work all right, is not suitable for the high production requirements of the present day. In such a built-up tool the line of fracture would be straight to the center of the cutoff tool, so we should lose the cutter and have to replace it. This would, very likely, be a frequent occurrence, owing to the lack of support, caused by minute particles of scale, grit, etc., getting between the disks of the tool while assembling. Nothing is perfect, you know; and while we all know the impossibility of making anything dead true, it is also a fact that nothing can be made perfectly clean. It is the unavoidable dirt and grit that would cause trouble.

Furthermore, a built-up tool is capable of very little grinding, since in grinding out a rivet not only a great deal of valuable tool steel is lost, but the tool is greatly weakened. The grinding operation mentioned is really quite simple. In sharpening a solid formed tool it is simply spun on an arbor, a dished grinding wheel being used to give the correct wheel clearance. Any fairly good tool grinder could readily grind this forming tool.

In our practice we have found it better to use a solid forming tool. The tool is ground 5 deg. below the center and is set in the machine with exactly the same setting as that of the cutting-off tool which I described in *American Machinist*, Vol. 44, page 518. In a solid tool operating on cold-rolled steel the line of fracture will approximate a vertical line, from the cutting point downward, of a depth about equal to the depth of the cut. Breakage is not so very common, the tool as a rule simply requiring grinding—that is, sharpening. As a good general average we might say that the formed tool, in case of fracture, would break about $\frac{1}{8}$ in. back from the cutting edge. Sometimes, but rarely, the break will be, or even exceed, $\frac{1}{4}$ in.

Generally speaking, to meet present-day conditions give me the faster, more easily made and more economical solid forming tool. J. B. MURPHY.

Plainfield, N. J.

Machinist Instruction in the Public-School System

On page 606 Mr. MacKenzie touched upon a rather delicate subject when he mentioned the difficulty of obtaining commercial work for trade and vocational schools and disposing of it upon favorable terms.

Inspection of the machine shops in the various trade schools in Massachusetts will show this to be true to anyone who recognizes commercial work when he sees it. This inspection will sometimes reveal also the reason why it is difficult to obtain such work—namely, a lack of confidence on the manufacturers' part in the ability of the schools to turn out machine parts that will stand the acid test of the commercial inspectors.

The manufacturers do well to refrain from placing orders with such trade institutions until the schools have, in a measure at least, demonstrated their ability to do work that in proper selection of material, in accuracy of execution and nicety of finish meets the requirements of the commercial standard.

However, with the proper equipment and methods of doing the work it is not impossible even with boys to manufacture machine parts that will be acceptable to responsible machine-tool builders. As evidence of this statement one of the Massachusetts trade schools has sold thousands of such parts to the manufacturers in the past few years, has under way several thousand such parts at present and would have no difficulty in obtaining orders for thousands more. That is only one department of a

school in which there are others doing the same thing on a smaller scale with less equipment and operating expense.

Apparently, the way to convince the men of responsibility in the commercial world that the schools can produce quality work is the same as in any other line—by doing it.

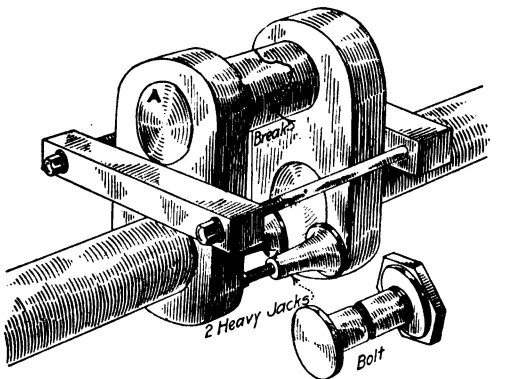
As to the boys' proneness to say, "We did it this way at the school," and to believe firmly that no other method is correct, the writer is inclined to attribute such an attitude to lack of experience rather than to consider it characteristic of the vocational-school product. Do we not all recall the younger and less experienced men coming into the commercial shops and saying almost the same as the schoolboy did, "We used to do it this way at the old shop," or, "That ain't the way we did it down to Reed's"?

Sterling Junction, Mass. M. H. FERGUSON.

Crankpin Repair Job

The article by James Ellis on page 470 reminds me that twice I have had similar work to do in our small shop, but was obliged to follow a different method. Owing to the fact that the equipment was somewhat limited, the whole job was done in the lathe.

The crankshafts were about 5 in. in diameter, and the pin in both cases was broken very irregularly—a condition that made it possible to avoid keyseating. First, the two halves were placed on blocks and the broken ends of the pin brought together. A clamp was made from 2-in. square iron, and 1¼-in. bolts were put around



CRANKPIN REPAIR KINK

the throws near the shaft, as shown in the illustration. Between the throws on the two corners farthest from the pin were set two heavy jacks, and the clamp bolts were tightened, bolts and jacks being adjusted to bring the two ends of the shaft nearly in line.

The shaft was then placed on centers in the lathe and the jacks and bolts adjusted until the shaft ran as true as possible. The shaft, still clamped together, was bolted to the carriage of the lathe on suitable blocking, with the center line of the crankpin approximately in line with the lathe centers. With a drill with a long extension held in the chuck serving as an improvised boring bar, a 3-in. hole was bored through the crankpin and counterbored at each end to receive the head and part of the nut of the bolt.

A bolt was made, as shown, a drive fit in the 3-in. hole, with the head to fit the counterbore. A nut with the hexagon turned off to fit the counterbore was also provided, leaving enough of the hexagon projecting to tighten up with a big wrench. This bolt was driven in and the nut tightened, after which, the clamp and jacks were removed and the shaft again placed on centers. The bearings were turned and the rough edges of the break filed off, finishing the repair. The nut, which had a rather fine thread, held the rough edges of the break together so tight that keys were unnecessary.

Morrisville, Vt. J. O. REED.

Counting Gear-Wheel Teeth

The simple little kink of "marking the space instead of a tooth," given us by Mr. Fletcher on page 1041, Vol. 43, caught me right in the neck, as it did Professor Sweet, and like him I tried it on my foreman millwright and some other boys. I must admit that we all appeared very small.

On page 295, Vol. 44, F. R. Mann takes exception to this idea, offering us a better way—"Mark the tooth and count the space"—telling us the chances of going wrong are materially lessened, because Mr. Fletcher's method does not take into consideration that "there are as many spaces as teeth in a gear." He also requires training our method of thought in another direction to make his method workable, which summed up in a few words means, "Change your count and leave the mark alone." Mr. Fletcher tells us "Change your mark and leave the count alone," and it requires no stretch of the imagination to decide which is the simple method.

After reading Mr. Mann's suggestions I decided on further experiments. Securing a 49-tooth wheel from the toolroom lathe, I placed it before my own special draftsman (a clever man with jigs and tools), with the numbered side downward, of course, and asked him to count the teeth. He commenced by marking a tooth and counted 49, then counted again because he thought it should have 50 teeth. The second count also produced 49, but he would not swear it was correct without another count, marking off the teeth in fives. I then suggested Mr. Fletcher's method—to mark a space—and after a trial he was quite satisfied that his method had been wrong. I then introduced Mr. Mann's suggestions, and after practical experiments we could not accept it as meeting the case.

Of course, we all believe in and carry out the casting or stamping of the number of teeth on wheels whenever possible, but many of us who have the handling of repairs and alterations to machinery must still rely upon the count as the only method of finding the number of teeth in a wheel. At least a dozen men in my own circle, including myself, will find this simplified by the suggestion of Mr. Fletcher, "Mark the space and count the teeth," leaving Mr. Mann's suggestion severely alone for several reasons, one of which may be given—because there are as many teeth as spaces in a gear—a fact that appears to have been entirely overlooked by Mr. Mann in accusing Mr. Fletcher of neglecting the obverse.

Belfast, Ireland. F. P. TERRY.

Wire Covered with Enamel is gaining in application for certain electrical uses in tropical climates. It is claimed such wire has withstood an electrical pressure of 1,000 volts after immersion in caustic soda, sulphuric acid, nitric acid and hydrochloric acid for 48 hours each and in potash 35 minutes.

Metric System in Export Trade

By Henry R. Towne*

An editorial commenting on a reference to the metric system in a recent report by Dr. S. W. Stratton, Director of the Bureau of Standards, Washington, was published on page 563 of the *American Machinist*. Having long been a student of the metric question as related to our national interests, I became interested in ascertaining the origin of the report in question and the facts concerning the use of the metric system by the American manufacturers who were named in that report.

For the first of these purposes I called on Doctor Stratton in Washington, who explained to me the origin of the report and stated that one of his objects in writing it was to show the extent to which American manufacturers are responding already to the preference of their foreign customers for the use of the metric system in export trade. For the other purpose I addressed letters of inquiry to the manufacturers named in the report. The result of these investigations is summed up in the following statement.

A report entitled "Metric System in Export Trade," by Dr. S. W. Stratton, Director of the Bureau of Standards, prepared by request of the Secretary of Commerce, was transmitted by him to the Secretary of the Treasury in November, 1915, for use by the latter when attending the meeting of the International High Commission on Uniformity of Laws, in Buenos Aires, in March, 1916.

In that report fifteen American manufacturers were named as examples of the large number who are "already using the metric system." Desiring to ascertain the extent to which this statement conformed to the facts, I addressed a circular letter of inquiry, dated Mar. 27, 1916, to each of the parties named, requesting brief answers to the following questions:

1. What proportion of your product is made to metric dimensions?
2. Do you use metric measures except in executing orders which require them, and if so, why?
3. In executing orders based on metric measures, do your workmen need to make large use of metric scales or are they guided by gages and templets furnished to them?
4. Do you favor legislation intended to compel the ultimate abandonment of our present units of length and the substitution therefor of metric units?
5. If not, for what reasons are you opposed to such changes?

Replies were received from all but two of the parties addressed, the character of which is indicated by the following extracts:

American Locomotive Co.—"Are using metric system when the purchaser requires it. Not a very large proportion of our output. Workmen guided chiefly by gages and templets, not largely by metric scales. Do not favor compulsory legislation, which would work a great hardship and cause confusion and unnecessary expense."

Baldwin Locomotive Works—"Do not use metric system except when specified. Have built 300 locomotives in all to metric measures. No inconvenience in using them; indifferent as to legislation."

Brown & Sharpe Manufacturing Co.—"Make tools to metric system for sale in metric countries, but use the English system entirely as a basis for work. Strongly opposed to compulsory measures which would introduce 'endless confusion which would continue for generations to come.'"

Pratt & Whitney—"Use metric measures in making taps and cutters for metric countries; in tool department only use them to 'an infinitesimal degree.' Never called on to use them in filling orders for machine tools. Are opposed to the change. If made, all scales, gages, measuring instruments and drawings would be worthless and require replacement at very great expense."

Waltham Watch Co.—No reply.

Standard Tool Co.—"Proportion of product made to metric dimensions is very small. Metric measures used in the manufacture of tools and may become universal 'sometime in the future.' Think manufacturers should not be compelled to adopt metric system."

Morse Twist Drill and Machine Co.—"Only use metric measures when specifically ordered. Workmen easily shift from one standard to the other. Do not favor compulsory legislation. To effect change 'would take so long that most of those now here would be obliterated before it could be accomplished.'"

Bausch & Lomb Optical Co.—"Have used the metric system for a great many years in making lenses and prefer it. In mechanical work, however, the English standards still in use 'on account of the great expense that would be involved in changing.' Do not advise compulsory legislation. Refer to fact that English inch is still used in Germany in steam, gas and water piping, although metric system adopted 45 years ago."

Eastman Kodak Co.—"Use metric system on very small proportion of product and almost wholly on export orders. Workmen using it guided by gages and templets, not by scales. Are opposed to compulsory legislation."

The Lufkin Rule Co.—"Not using the metric system for manufacturing purposes, 'but thoroughly indorse the system and believe that compulsory use of it in the United States would be of inestimable benefit.' About 5 per cent. of product made to metric measures, which are used only when called for. Favor compulsory legislation."

International Exporting and Importing Corporation—No reply.

Keuffel & Esser Co.—"Find no difficulty in working to metric standards, which are used for all optical measurements and calculations and also throughout the chemical profession. In our opinion there can be no doubt but that eventually the metric system will be adopted in this country as the only standard system, and that it would be best to hasten this date."

Powers-Weightman-Rosengarten Co.—"Only use metric system in a small way for occasional export orders. Not unalterably opposed to the change, but favor retention of the present system."

Library Bureau—"Originally used metric measures, but have recently changed to measures based on the inch. Only now use metric measurements when orders so specify. Do not favor compulsory legislation."

L. S. Starrett Co.—"Do not use metric measures except in executing orders which require them. Realize advantages of metric system, 'but on account of the infinite labor and expense of changing do not favor compulsory legislation.'"

A letter dated Apr. 7, 1916, from Doctor Stratton, on whom I had previously called and to whom I had shown the letters from which the foregoing extracts were made contains the following statements:

*Chairman of the board, The Yale & Towne Manufacturing Co.

It was our intention in this report to show that American manufacturers are meeting the needs of export trade as far as the metric system is concerned. It was not in any way intended as a metric propaganda. I am in favor of the metric system because it is a decimal system and because of its international character.

As to the method of adopting the metric system, my position has always been that its use should only be made compulsory in the ordinary affairs of commerce and trade, that manufacturers of machinery and other articles should be allowed to use whichever system they desire in their construction. In this manner only the output of the machine will be affected. Manufacturers of machinery should not be required to do any more than they are now doing to meet the needs of those countries in which the metric system is now in general use.

Industrial Preparedness from the Engineer's Viewpoint

SYNOPSIS—A continuation of the discussion on organizing for industrial preparedness presented at the New Orleans meeting of the American Society of Mechanical Engineers.

Put Engineers in Charge of Manufacturing

By Elmer H. Neff

I think Fred J. Miller's discussion has touched upon one of the most important elements that this society through its committees might investigate, and that is the question of the efficiency of the organization of the army and navy as at present administered—the question of the returns for the dollars that are being spent, which it would seem from the facts in Mr. Miller's letter are exceedingly small. This might very well be the subject of investigation by this committee.

Probably you have noticed in the public press that the navy is very short of officers. If you visit one of the navy yards, you find every department in charge of a naval officer overseeing in many cases if not in most cases, operations with which he has no familiarity whatever. The proper place for that kind of man, in my opinion, is on board a ship, where, we are continually being told, there is a shortage of men and of officers. In every arsenal you find army officers in charge, men who are not familiar with the work of manufacturing and who have had no experience whatsoever in that direction except what they have simply picked up while detailed to some particular place. Colonels, majors, captains are here a few months and at the next arsenal the next few months. There is no possibility, so far as I have been able to see, that there could be efficient administration under that sort of management.

As you well know, the British Government found out after the war had progressed a few months that it needed a munitions department. The United States of America needs in its army and in its navy a manufacturing department run by engineers. Then the gentlemen who are educated to manage ships and the operation of the men in the field can continue to perform the duties for which they are educated, while men such as you would place in charge of your factories shall be in charge of the manufacturing departments. If such an arrangement were effected, I believe the question of efficiency would be met, that there would not be the tremendous expenditures out of all proportion to returns, such as are indicated by Mr. Miller's letter.

A Census of Resources

By A. L. De Leeuw

I thoroughly believe in making a census of all our resources, which may lead to ultimate industrial preparedness. I should like to suggest, in addition, the desirability of making a census of those facts and conditions that may stand in the way of industrial preparedness.

I have been personally able to observe some of the conditions imposed by the Government upon making munitions for guns. These requirements are probably all right if nobody is in a hurry and if all we want is just a beautifully made piece of mechanism. But these conditions should not exist if we want guns that will shoot tolerably rapidly, tolerably close and that can be manufactured in a minimum of time. I refer here especially to the matter of limitations. In this case I do not believe the Government specifications or limitations are any worse than you will find in almost any industrial establishment; but it has also been our experience that in any shop there are limitations that are entirely too fine. They have simply crept in and remained until somebody suddenly wakes up and discovers them.

This statement holds good not only for guns, but also for ammunition and all other materials. The census of all those conditions that might be avoided should treat not merely of things that the Government has done which we would like to have changed, but also of things which ordinary private citizens have done. If the Government should ever send out jigs and fixtures to be used in various shops, there would arise the impossibility of taking a jig from one machine and putting it into another, taking it from one shop and placing it in another.

I realize full well it would not be possible, in the course of a few years, to have all planers or shapers, of exactly the same size and have all spindles the same size, but something ought to be done to prevent the annoyance of too much variation, the variation being simply the expression of the desire of some manufacturer to push his product at the expense of his neighbor. If there is any particular reason why his size is superior to his neighbor's, there is no reason why it should not be accepted by his neighbor also; but if there is not, the census I have mentioned should take into account the delay and the annoyance that might be caused by having too great a variation of design and size in machines. This applies not only to machines, but to everything. I should therefore recommend that in addition to the census of factory materials, machines, men, executives and so on there should also be taken a census or list or a tabulation of conditions that prevent the speedy and easy manufacture of those materials and products which we need.

Securing Skilled Workers

By H. T. Wright

In one city in the South there is a fund of nearly $1,000,000 for the establishment of a trade school. That fund has been available, I understand, for some time, but ground has not been broken for that trade school. I have been connected with the mechanical work in the vicinity of that city. I have had young boys come in to me, boys of 18, 20 and 22 years of age to work as laborers—intelligent men. When I asked them whether they ever attempted to learn a trade, they told me yes, but there was no such thing as the apprenticeship system in the city where they were working. Yet we have no trade school in that city today. What are we going to do about the men? We cannot mobilize an army of workmen unless we first educate them. You gentlemen who come from the Northern states know the splendid apprenticeship system of the Western Electric Co., the apprenticeship system of the Fore River Shipbuilding Co. Down here there is nothing that parallels those systems, because of the fact that we have not enough work to train our apprentices.

It is going to take a long time to build up that force of workingmen who must be the backbone of any industrial preparedness. No matter how much raw material you have available, no matter how many machine shops you have lying idle, you cannot obtain industrial preparedness without the men to manufacture the raw materials and operate the shops.

Very few of us know about the women who are willing to be employees in the manufacture of war supplies. All we have to do to see the result of the employment of women in the matter of industrial preparedness is to look at Great Britain today. Why not have, as an addition to the agricultural schools, trade schools where girls can be educated

at the public expenses, so as to give them a fundamental knowledge of the trades in order that they will be ready to step into the places of the men that have to go to the front to carry the rifle and operate the guns?

Another speaker said that Government specifications must not be too severe. The specifications must be reasonable; but we have also to consider that we must get everything that we can out of the material. We must consider what material we are going to use in each part of the machine or the gun and then get the best out of that. The question of tolerances was brought up; the necessity of the parts fitting; that all you needed was proper correlation of parts. Perhaps it is not realized that the navy retubes every one of its big guns. When a gun is taken off a ship, after it has been fired 200 or 250 times, that gun is retubed. When you are going to use your materials over and over again, merely replacing defective parts, mechanical tolerances have got to be watched pretty closely.

Bearing on the question of the education of the mechanic and touching closely the question of the mobilization of the American women in industrial preparedness, comes the question of coöperation. The most concise statement of coöperation will be found in the words of Fred W. Taylor: "The time has come when all great things will be accomplished by the coöperation of many individuals, each performing the function for which he is best suited, each supreme in his particular function, yet retaining his individuality, while collaborating with his fellows toward the production of the complete and perfect whole."

An Army Officer's View

By Maj. W. Goff Caples

I feel sure that something of the kind is needed very much. We should know accurately what we can rely on in the case of war. We will need assistance from everyone—the engineer, the chemist, the manufacturer and the man in the mills—and I am glad to see that an interest in this subject of industrial preparedness is being taken here by you.

I was engaged for 2½ years in the organization and equipment of troops. When we wanted to get military equipment, we did not meet very enthusiastic greetings from the manufacturers. They would say: "Well, what is the size of the business?" "At the present time, it is not attractive."

We know perfectly well that at the present time there are some misfits in our equipment. It may look queer that we have to have for military equipment certain things that are not of ordinary commercial sizes; but it is true, on account of certain limitations, one of which is how much can you pile on a man's back. At the present we have to pile on about fifty pounds, and that load feels very much heavier at the end of a fifty-mile march that at the beginning. We want to have the men in condition to fight at the end of the march. Therefore, we must have special stuff.

The same thing applies to transportation. There is an immense amount of wheel transportation required in the movement of troops, and the general staff and the other officers have been trying to bring this down to a minimum. A few years ago a wagon train of a division was longer than the fighting troops with it, and considerable transportation is necessary to carry feed for the animals alone. We have tried to get the equipment down so as to have less weight for transportation than the ordinary commercial tools afford. In getting out things of that kind we have found considerable difficulty, and we have had trouble in getting out things like standard military explosives.

It is gratifying to find that everyone is taking an interest in national preparedness, because it concerns us all and we are all vitally affected by it. One thing that we have to be sure of in connection with national preparedness is that we shall have the men to utilize the guns that will be manufactured, the explosives that will be manufactured, the clothing that will be manufactured and the other things. It is nothing short of criminal to send a man out to fight unless he has been trained to do it. That is not a new thing. That was started over one hundred years ago, and it was firmly impressed in the minds of the men who organized our Government. The Revolutionary War would have been a total failure except for the aid given by the French, and there was put on the statute books of the United States in 1789 the first comprehensive law for compulsory military training. That law was put on the books at the behest of General Washington himself, and it stood on our statute books until 1903. It was a dead letter because of the fear of a central government. There was no penalty clause in the act, and its enforcement was left to the states. None of them provided suitable enforcement, and the thing fell of its own weight.

We have had several propositions put up from time to time as to what should be done to secure an army in case of need. It is out of the question to attempt to have a large regular army. Carthage tried to hire its defense and made a failure of it, and no nation since has made a success of it. The only way that a nation can be defended is by its own citizens. When it comes to the question of national defense, we have got to consider national economics. We do not want to spare anyone; but when war comes, somebody has to be spared. We ought to figure out who are the men that we can best spare and put them out on the first line. The men that we can best spare are the men who have the fewest dependents.

There is another extremely objectionable thing that comes up with voluntary enlistment. The men who volunteer and go to the front at first have good stuff in them. They are killed off, and the future of the race depends upon those who are left. You build up your race out of its poorest stock and kill off the others. Under the system of universal training, the Government says which men shall go. It takes from all classes equally, and you lose from all classes equally. As far as that is concerned, it is a problem of distinct gain.

It takes about thirty years to bring up a trained corps of officers. What you gentlemen are doing is something that I think is very much needed—a knowledge of what we can count on, of where we are weak and how we can remedy those defects. I hope that the country at large sees clearly that to put into effect the information which you want to give, to get the value out of it, a sacrifice must be made and the principle recognized that manhood suffrage means manhood service.

The Importance of Securing Workmen for a Plant

By Harrington Emerson

I should like to tell you an experience that one of my friends had with a munitions plant that he organized a year ago in the South. There were no buildings, no machines, no employees. He told his assistant that they would subdivide the work; that he himself would look after the equipment, getting the buildings up, securing all the necessary machinery (much of which had to be designed), and that it would be the assistant's duty to have the men, when the time came, to go to work.

The assistant sulked. He had no desire to be sidetracked in that way, put on the job of employing men when he had expected to do executive work. The head of the concern said to him: "You seem to miss the whole point. You don't know that you have the biggest job that was ever offered to any man in connection with this work. You don't seem to know that you have got to have on hand, listed and ready for this plant, over 20,000 men in order that we may pick from them 2,000 of the kind that we need. What I expect of you is that when I call for men you will have them ready."

That woke the young man up to the importance of the undertaking that had been assigned to him. Then he went out into the country—South, West, North. He went South into North Carolina and as far as Georgia, and he collected the names of a great number of farm boys—boys who had been on the farm, boys who knew how to handle tools, to mend harness, who knew how to mend a wagon, to sharpen a plowshare, to do carpenter work about the house, boys that were all-around crude mechanics—and those boys were investigated. Owing to the war difficulty, they applied the principle of selection to a greater degree than I have ever seen it applied before anywhere, except perhaps for admission to West Point and to Annapolis.

Those boys were there when they were wanted, some 1,600 in all. The foreman had been told in advance what they were to do, and he had prepared for them. Each one was to be given two or three days' special instruction, the foreman having been obliged, first, to demonstrate his own ability in running a particular machine and turning out the work. In fact, the plant had been run by the foreman on a small scale for a few weeks before the recruits came in. The boys were put on the jobs, and inside of a week they were making the foremen hustle. One of the foremen told me that in all his experience of many years in one of the largest plants in the United States he had never brought together so good a lot of workmen as he had in that plant inside of three months. So there is hope here in America of finding the raw material, if we go about it in the right way.

Need of General Preparedness

By Frank B. Gilbreth

This problem of preparedness is not the problem merely of preparing for war, but also of preparing for efficient living at any time. It is a problem of obtaining a greater general education and a greater individual education in the same learning period. It is a problem of national elimination of unnecessary waste, of adequate general and individual effort toward utilization and conservation of our great resources.

This national preparedness divides itself, then, into two lines: (1) Preparedness of material things—that is, surroundings, living conditions, all of the material objects with which we deal; (2) preparedness of people, as individuals and as constituting society. In both these lines of preparation our problem in the United States is extremely complicated. Our form of government, with all its advantages, seriously lacks correlation of activities in many places and a permanent centralized department for the planning and development of definite lines of national progress. This we must supply through a uniform and universal realization of what preparedness means and what it is for.

There is perhaps no need to enter now into the necessity for Government ownership of railroads, telephones, telegraphs and other public utilities, so necessary for defense, but this must at least be kept in mind. Without disturbing, for the present, existing ownership of these utilities, much can be done toward unification by requiring railroads to adopt all Government standards, even down to the exclusive use of the Government's map for the timetable folders; requiring that all transportation companies operate and plan for the sudden need; and so standardizing design and equipment of all such utilities as to make a system of interchangeable parts where possible. The possibilities of the complete utilization of our national opportunities should be a matter of public knowledge and instruction.

We can establish standards of motor-truck, motor-bus, motor-car, motor-boat and motor-bicycle efficiency that will not only prepare these speed vehicles for greater service in peace times, but will transform them into a most valuable auxiliary corps in case of war.

Much has been said of proper inventory of our individual equipment and resources and a standardization of jigs, fixtures, templets and equipment of our factories and plants. Such an inventory must include information as to our naval stations, so that we shall judge the value of the location of our naval bases from the standpoint of their usefulness and not by the pork-barrel units of the appropriations. Such standardization will automatically return to their ships and their troops the officers now stationed at work for which they are not specially fitted and which can be done by civilians who have not had military training. Let us at once apply measurement and standardization to all these problems of material preparedness, so that every officer and each one of us can do his own work with all the might that is in him, knowing that the finished products are bound to be what is required.

Efficient preparedness is not only for the army and navy or of the men available for military service. It is preparedness of every man, woman and child in the country. Abroad, children are trained to spend much time out of doors and in out-of-door activity. Endurance is secured by out-of-door walks and contests. Thrift is instilled through its practice in the homes, even to the general custom of serving small portions at the table, with the intention of passing food many times rather than encourage the smallest portion being left over. To take more than one wants is considered as a misdemeanor and an unpatriotic act.

Women should be prepared as well as men, prepared by a training in physical endurance; by manual training, education in household economics and in nursing. This has made it possible for women in the countries abroad to take up the work of men in all lines of activity where it is necessary.

I would recommend that no man get a license for running an engine of any kind or motor busses, motor boats, etc., till he qualifies also on machine-gun assembly and operation. This training implies an opportunity open to all to learn to operate such machines. In many of the large national museums abroad are found working models that may be freely handled by the smallest boy. Practice machines, available to boys and girls of any age, teach them to be observant at an early age.

It is not enough that the equipments and tools of the sudden need be made available. The methods of handling them must be taught in such a manner that the workers may gain not only a knowledge of the machine that makes the machines, but an idea of motion economy and of personal effectiveness.

The important thing is rather to reëmphasize that preparedness means not merely getting ready for war, but getting ready for real living. What should shock us is not what might happen to us in a war, but what is happening right now, while there is general peace. National waste, lack of general and specific education, lack of easy means for obtaining the fullest education in the vocation for the worker in that vocation, lack of correlation! The "Spirit of 1776" is with us now, and so are the arms and ammunition of the same date. We have right here today the greatest opportunities that the world has ever offered. Let us not arm for a definite enemy, for tomorrow there may arise conditions that will cause us to revise our list of probable friends and probable enemies. Let us educate ourselves for individual and national efficiency.

The Chemist's Part

By C. S. Williamson

Attention is called to the fact that there are certain phases of investigation for the chemist. These subjects include gasoline, which means fuels; grain alcohol, which can be construed for either fuels or for extracted purposes, the alcohol to be derived from sawdust and other wood waste, sugar-house waste and cornstalks.

The production of alcohol from sawdust is beyond the experimental stage. It has been accomplished not on the experimental basis alone, but on a commercial basis; and as we chemists see it now, only two things remain to be done in regard to alcohol—one is the design of a motor that will use it, because it has a heat value two-thirds that of gasoline; and the other is the necessity of a tax-free alcohol for the safety of the state.

Nothing has been said in regard to national preparedness from the standpoint of medicines, nothing except from the standpoint of ammunition. Alcohol plays a part in regard to both these questions. In the case of ammunition we may use denatured alcohol, but not in the case of medicines. For that reason many of the medicines that we import are not produced in the states, because we have not an alcohol with which we may produce them. Denaturing alcohol with fluorine, which is commonly used, or with benzol or benzine renders it unfit for the extraction of certain medicines. The maintenance of an army is just as important when looked at from the standpoint of medicines as it is from some other sources, so we chemists have accomplished the extraction of alcohol from some other sources besides grain and molasses, because we have produced it from sawdust as cheaply as, if not cheaper than, from molasses, which is our common source in the South.

We are producing ammunition today for the fighting countries, but we are producing it from materials brought from another country. If we were thrown on our own resources today, we should have but 25 per cent. of the required amount of nitrate of soda available in the states for the manufacture of munitions. We import one-fifth of the production of the Chile mines. We use 75 per cent. of that in the manufacture of munitions, the other 25 per cent. being left in the fertilizer industry and for other purposes, which means that if we were suddenly cut off from our supply, we should have 25 per cent. left to deal with, which would be exhausted after a short while.

We hope this situation may seem pertinent to the United States Government, for the reason that we cannot make an explosive without the use of nitric acid. We cannot make nitric acid in America today, with the exception of one small experimental plant and a few small units in plants devoted to processes, except from Chilean nitrates. As I understand industrial preparedness, it is preparing for an emergency. It is especially significant to use when we recall that the manufacture of nitric acid by the synthetic process—the oxidation of nitrogen from the atmosphere—had its birth on American soil. Nitric acid is produced synthetically today in Norway and Sweden, because of their cheap water power. Since the outbreak of the war Germany has spent $100,000,000 for the production of nitric acid plants. Nitric acid is used in every dyestuff that we have and in many other processes.

Coöperation between the work of the engineer and the chemist is necessary and should be corelated, because of the fact that for every dyestuff and for every explosive we have to have heavy chemicals; for the manufacture of heavy chemicals, we have to have sulphuric acid. For the manufacture of explosives we have to have sulphuric acid, alkali and nitric acid. The chemist's problems are the engineer's problems. We are working hand in hand; one is absolutely dependent upon the other.

Editorials

Metric System in Export Trade

We hope no reader will fail to read Mr. Towne's communication on page 825 and compare the trifling use of the metric system disclosed by his inquiry with the impression conveyed by Dr. Stratton's listing of those manufacturers in his report on the metric system in export trade as "using" the system.

We also recommend to the attention of all the fact that the Library Bureau announces that it has given up the system. For 20 years this bureau has been a standing reference of the metric party as an example of the progress of the system in this country, and it now joins the procession of those who have tried the metric system only to abandon it. Chief of these is the firm of Willans & Robinson, of Rugby, England, who with a new product and a new shop, without old practice to interfere, adopted the system under the most favorable conditions under which it has ever been tried in English-speaking countries. Its advantages were found to be imaginary, and after 10 or 12 years' trial they gave it up for all new lines of work, although continuing it for the old, because of the difficulty of getting rid of established metric sizes.

Another case of the same kind is that of the American Solvay Process Co., which after adopting the metric system at the building of its plant later gave it up for the mechanical side of the work. Along with these instances all know the experience of William Sellers & Co., who adopted this system in beginning the manufacture of injectors, but who after a half-century of experience with it condemn it and would be glad to get rid of it, which, established as it is in their injector department, they cannot do.

What is the use of talking about the wonderful advantages of this thing when those who have tried it find, after the glamour of novelty has worn off, that the advantages do not exist?

Dr. Stratton's disclaimer at the end of Mr. Towne's letter must be read in the light of his record. When the bill of a dozen years ago was before the House Committee on Coinage, Weights and Measures, Dr. Stratton was always present at the hearings to urge the passage of the bill, which, as everyone knows, was compulsory on all manufacturers who dealt with the Government. Those hearings showed Dr. Stratton the strength of the opposition among manufacturers, and he has changed his program to an attack on the general public, which is without organization with which to oppose his plans.

Used in this limited commercial way, where does the uniformity of the system come in? When the manufacturers buy raw material and sell their finished products by one system and conduct all intermediate factory work in another, we will certainly have a beautiful example of "uniformity." It is exactly this condition in the textile industry of metric Europe which Mr. Dale has exposed as the cause of complexity and confusion.

No one has ever shown, because no one can show, the slightest superiority of the meter over the yard, of the kilogram over the pound or of the liter over the quart for commercial transactions. This side of the case was completely given away by Dr. Simon Newcomb—one of the most ardent of the metric party—who in a moment of forgetfulness said before the House Committee on Coinage, Weights and Measures: "So far as everyday purposes are concerned, I do not know of any particular advantage."

Meanwhile Dr. Stratton is on record as favoring compulsion in commerce and trade. The simple fact is that he wants all, but for the time being will accept anything he can get.

Future for Machine Tools in South America

Previous editorials on pages 697 and 741 have given statistics in regard to the machine tools, mechanics and shop executives of South American machine shops. With this information as a foundation it is very much in order to ask, "What is the future for North American machine tools in South American markets?" No other general reply can be considered except, "The prospects were never brighter than they are today."

The statistics previously given show in round numbers 460 shops, 11,500 machine tools and 14,500 workmen and executives attempting to do the machinery repairing and some part of the machinery building for a population of 40,000,000 persons. It is estimated that there are some 22,000 machine shops in the United States serving a population of 100,000,000. The prospects for machine-shop growth in the great southern continent are stupendous, even although South America never begins to manufacture machinery in the way in which it is produced in the United States. As that tremendously rich continent passes through the stages of development that this country traversed during the last century, machine shop after machine shop must come into being in order to care for the upkeep of the ever-increasing volume of machinery used in agriculture, transportation, mining and the thousand and one other uses to which machinery is put. With the locomotive, gang plow, harvester, sawmill and stamp must go machine tools.

Thus the bright prospect for the enormous future demand of machine tools in South America rests, first, upon the tremendous undeveloped resources, the vast unexplored regions filled with natural wealth, the world's richest store of undeveloped water power, the enormous areas of fertile land that can only be made available by railway connections, the new cities and the awakening people. The frontier of the world's greatest treasures of natural resources is now shifting to South America. As the frontier of resources advances, the frontier of industrial development follows. Machine tools now play a tremendous part in inaugurating the agricultural and

industrial eras. Fifty years ago the work of pioneering was done by the muscles of men, women and animals. Today machinery accompanies both pioneer and settler.

A second conclusion has to do with prospects for the United States machine tools in South America. Again the prospect is of the brightest. The South Americans really like North American products. Of all the machine tools now in South America nearly 40 per cent. are United States made. This record stands in spite of the fact that North American manufacturers have made no serious efforts to develop and control the southern market, have insisted on selling on a cash basis and have been in competition with European houses that were willing to cater to the wishes and fancies of the southern buyer and sell on long credit.

Generally speaking, there are two classes of customers for machine tools in South America: First, those who buy for quality, such as the large railroad-repair and shipbuilding shops, and, second, those who cannot afford the best, but need and are satisfied with plain, simple machines of average quality. The first class is accustomed to buying the regular line of machine tools produced by United States builders. A large part of the North American made machines in South America were purchased by men who belong to this class.

The second class must be reached by supplying machine tools of fair quality, but lighter in weight and cheaper in price than those that are considered standard in the United States. The reduction in weight lowers the cost to the buyer by reducing the amount of material used, by lessening the freight and by cutting down the amount of the custom-house charges and duty. In the aggregate these three items make an appreciable sum.

One reason for the lack of past developments amid the tremendous resources of South America is found in the traits and characteristics of the people. The South American lacks the energy of the northern races when it comes to industrial development. This is now being recognized in the north as never before, and the logical corrective steps are about to be taken. North Americans are now talking of going to the great southern continent; banking connections have already been established in a few large centers; the necessity of lending money to South American governments is being discussed. Each one of these things will have its influence in developing the agricultural, timber, mining and water-power resources of the great frontier of the Western Hemisphere.

Many of the plans now being developed to reach South American business are being laid with the expectation that ten years will pass before the results will be appreciable. Unfortunately, this foresight is not an any too prominent characteristic of the North American business man. It argues well for the future that in at least this one direction some of his usual business habits are being overcome. Just at present the lack of shipping facilities is acute. But this fact is well recognized by North Americans, and unquestionably before this year passes into history something will be done to relieve the situation.

A familiar objection to a visit or residence in South America on the part of a northerner is that of unhealthful living conditions. It is very true that there are some parts of South America which it is unwise for a northerner to visit; but if one will let his memory go back only a few years, he will recall the quarantines of New Orleans against yellow fever and the unhealthful, unsanitary conditions of Havana and Panama. Until very recently these drove the northern visitor to take most unusual precautionary measures. Now these sections have been cleaned up, and what has been done there can be done elsewhere. The precedent has been set, experience has been gained, and it merely needs the will and the effort to do for South American cities what has been done for New Orleans and Havana.

When plans are being seriously formed by North American machine-tool builders for South American trade, two things must receive consideration and should not be forgotten. In fact, these two require action at home. The first is some legal way of holding back products of the shoddy manufacturer. Some means should be available whereby everything exported from the United States would be exactly as represented. Misbranding, misclassifying, the uttering of exaggerated and lying descriptions should be punished by heavy penalties. It is of course impossible to set up a standard of quality for machine tools in the same way that standards can be established for the purity of foods and drugs, but steps can be taken to prevent the sending forth of dishonest descriptions and to compel a manufacturer or shipper to furnish just exactly what he has advertised or guaranteed to supply.

The second point for consideration at home is the matter of combination or coöperation for foreign trade. It is believed that under our present anti-trust laws such combinations are illegal for United States manufacturers. If such is found to be the case, immediate steps should be taken to do away with this hindrance. One of the most successful ways to further machine-tool trade in South America will be through the coöperation and combination of manufacturers in export business.

The Buying of Machines

The buying of tools is in many respects like the purchasing of labor and carries with it the same tendencies to look only at the outlay instead of to compare this with the results obtained. In this way many go over the specifications of a machine, compare bearings, weights, belts, etc., and decide on the one that is best for their particular work.

Others go to the other extreme and pay no attention to the design, to the weight, belts or anything else except the results that the maker is willing to guarantee. Advocates of this plan contend that they are buying not only the machine, but the experience of the builder; that it is not their province to criticize the design, the size of bearings or the belts, so long as the machine can be depended on to do the work under the manufacturer's guarantee.

There are of course many objections to a guaranteed output, as so much depends on both the work and the operator; but on the other hand, it is safe to assume that the maker of a machine is in better position than anyone else to know what a machine will do. If he is not willing to guarantee a minimum production, after knowing the conditions, we may be justified in looking askance at the machine he builds.

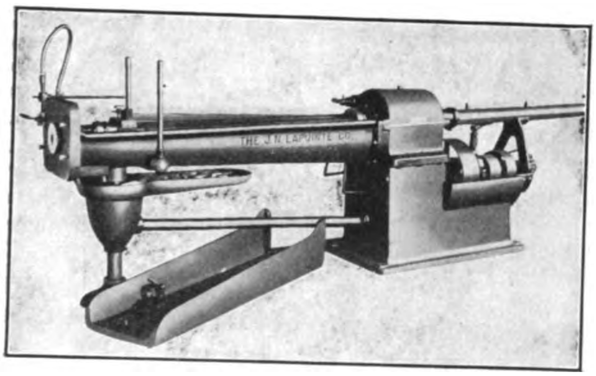
Some makers give very few details in their catalogs or elsewhere, believing that results should count and that the details of design are not necessary to the purchaser as long as the output of the machine is satisfactory in proportion to its cost. These are all problems for the careful buyer.

Shop Equipment News

Horizontal Broaching Machine

The broaching machine shown is the latest addition to the line made by the J. N. Lapointe Co., New London, Conn., and is known as the 3-B machine.

In general design and construction the machine follows the standard lines developed by the makers. All gears are incased, moving in a bath of oil, and two geared speeds are provided, which can be changed while the machine is running. A large roller thrust bearing is placed inside the gear casing to take the pressure of the cut and reduce the friction. The machine may be controlled either from the front or the rear, two operating handles being furnished. The size of the oil pump has been enlarged.



HORIZONTAL BROACHING MACHINE

Capacity, 1½ in. keyway, 10 in. long, or 3 in. square hole broached, 6 in. long; drive pulley, 18 in. diameter; travel of screw on low gear, 3 ft. per min.; driving screw, 2¾ in. diameter, 2 pitch, 54 in. stroke; floor space, 2½x16½ ft.; weight, 3,400 lb.

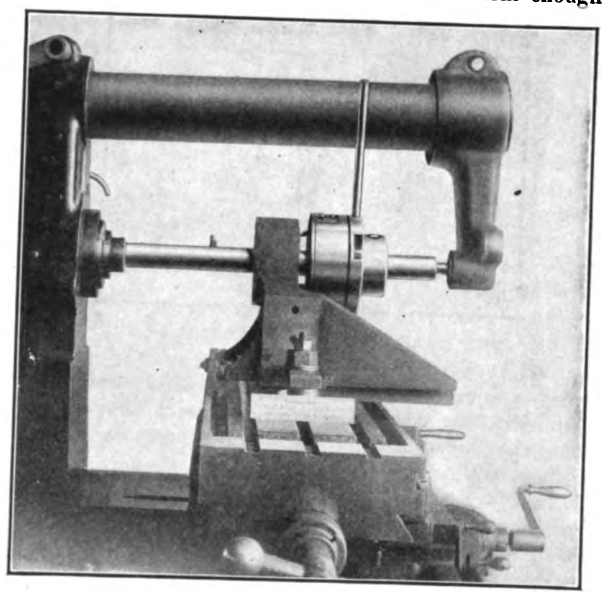
The machine is fitted with a duplex self-oiling clutch the lubrication for which is supplied from a reservoir. Automatic stops regulate the length of the stroke. The sliding head is fitted with bronze shoes designed to give a wearing surface of more lasting qualities than cast-iron ways.

Facing Head

The illustration shows a facing head that is built by the Mummert-Dixon Co., Hanover, Penn. These heads are made in three sizes—6, 9 and 12 in. They can be used in connection with a bar on any machine that will hold and drive the bar. The heads can also be used without a bar on the end of a spindle, such as that of drill presses, millers, etc., by supplying a tapered shank. The head, with its feeding arrangement, is self-contained.

To spot-face on a drill press has always been rather difficult. Ordinary flat spot-facing tools are hard to keep in order, and it is not easy to get them started under the scale of the iron. These tools overcome this trouble. The facing may start from the center and the tool bit feed outward, or it may start from the outside and feed in. The tool bit gets beneath the scale at the start and breaks it away as the tool is fed across the work. The tool bit is easily taken out and sharpened. The feed is effected by placing a pin in one of the holes in the feed ring and either holding it by hand or letting it bear against the frame of the machine. This operates the feed screw that moves the tool across the work.

When the head is used in connection with the taper shank on the end of a spindle that is not firm enough to steady it, a pilot projecting from the center of the head may be entered in the hole in the work. On this pilot, bushings can be placed to fit any size of hole.



FACING HEAD

A pilot with a center point is also provided for cases when there is no hole. The center is placed in a hole that is put in the work by a small center drill that, with its holder, is quickly attached with the facing head in place on the spindle.

Adjustable Drawing Board

The illustrations represent the latest developments of the Emmert Manufacturing Co., Waynesboro, Penn., in providing vertical adjustable drawing boards to which its combination T-square and protractor may be applied.

In Fig. 1 is shown a vertically inclined adjustable drawing board. The complete outfit consists of a drawing board adjustable to any desired angle and slidable to or from the draftsman, a cylindrical weight concealed behind the drawing board and used to counterbalance its weight in any position, a stationary base frame, a device for adjusting the swinging upper frame to different angles, a slidable horizontal board or leaf carrying a drawer, and an upright adjustable stand.

The drawing board is easily moved up or down to bring it into convenient position for the draftsman and on a level with his eyes, whether sitting or standing. When the work is on the lower half of the board, the latter is moved upward to the desired position; and when work is to be done on the upper half of the board, it is lowered. The board, being evenly balanced with just sufficient friction to hold it steadily in position, is moved without any noise.

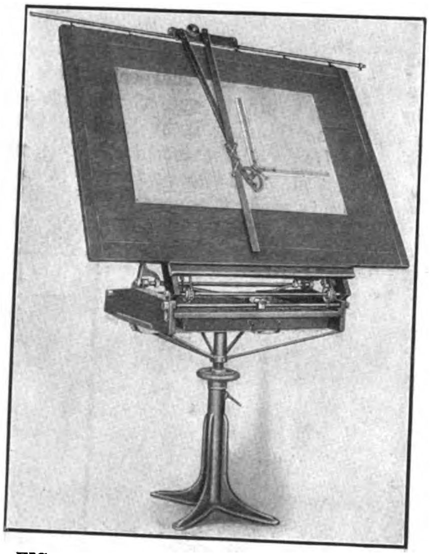


FIG. 1. ADJUSTABLE DRAWING BOARD

The draftsman need never twist or bend his spine to reach any part of the surface of the board, nor need he strain his eyes to read the fine graduations on the scale or the finer lines in the drawing, for with the aid of the adjustable vertical board he may assume a comfortable, normal position and adjust the distance between drawing and eye for correct vision.

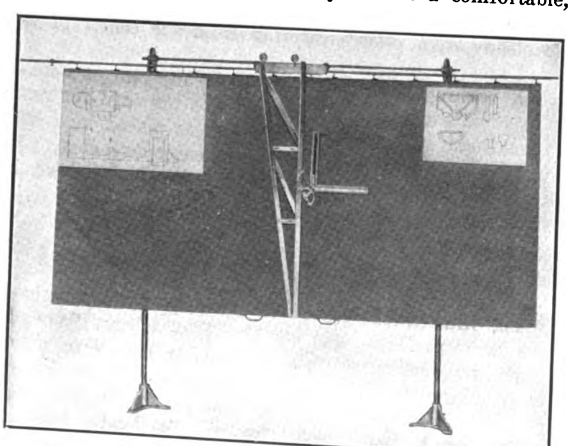

FIG. 2. ADJUSTABLE DRAWING BOARD FOR LARGE ASSEMBLIES AND LAYOUTS

The adjustable vertical board may be readily changed to the ordinary horizontal position where such position is preferable for inking, etc.

The adjustable floor stand provides a means for raising or lowering the drawing board and its attendant frame to accommodate the stature of the draftsman and to bring the drawing into position most favorable to light changes in the drawing room.

The board shown in Fig. 2 is intended especially for large assembled drawings, full-sized drawings, layouts, etc.

The board travels almost vertically a distance of from 4 to 5 ft. up and down on the supporting posts. Attached to its rear surface are the two sets of iron brackets carrying hardwood rollers, which rollers move against the supporting upright posts. The board is inclined at an angle of 3 deg., just sufficient to permit the rollers to bear slightly against the upright posts. The upward and downward movement is noiseless and requires but little effort on the part of the draftsman.

The upper set of brackets accommodate two ropes that pass over grooved pulleys at the top of the upright posts and are fastened to a balance weight. The grooved pulleys are joined by a connecting-rod and revolve together, thus providing an even movement at either end of the drawing board.

The counterbalance consists of a plain wooden box that may be filled with any suitable material, such as sand, scrap iron, etc., in sufficient quantity to balance evenly the weight of the drawing board. The upright posts are used in pairs, but for boards 15 to 20 ft. long, three posts should be used.

Micrometer for Measuring Tools with Three Flutes

The illustrations show a micrometer made by the L. S. Starrett Co., Athol, Mass., for the Union Twist Drill Co., also of Athol. With this tool the diameters of three-fluted drills, taps, cutters and so forth can be accurately measured.

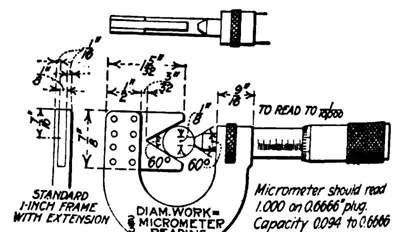

FIG. 1. DETAILS OF MICROMETER

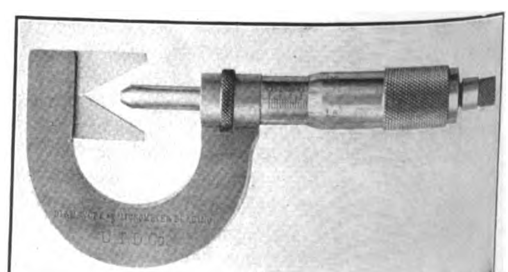

FIG. 2. MICROMETER FOR MEASURING THREE-FLUTED TOOLS

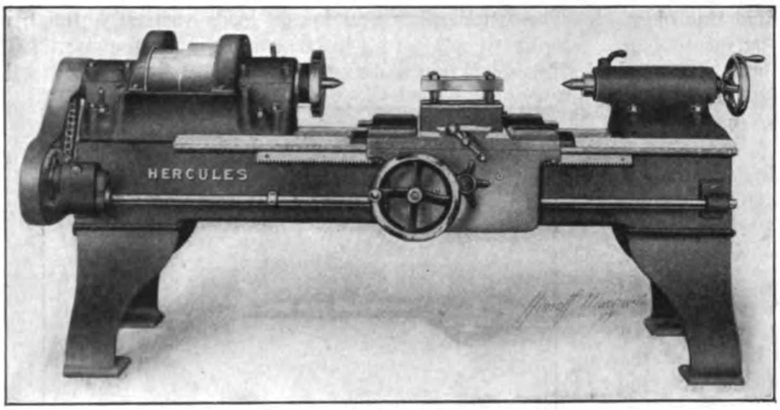
The anvil of the micrometer is replaced by a 60-deg. V-block. The tool to be measured is laid in this V-block, as shown in Fig. 1, resting on two of its teeth. The spindle is then brought down on the remaining tooth. The diameter of the work equals two-thirds the micrometer reading. The micrometer shown reads to 0.0001 in.

Single-Purpose Lathe

The lathe illustrated is of the single-purpose type, back geared, and in design and construction follows the standard lines developed for this particular class of tool.



SINGLE-PURPOSE LATHE

Swing, 16 in.; distance between centers, 40 in.; height from floor to center, 40 in.; belt, 5½ in. wide. Also made in 20-in. swing size

The machine is a recent product of the Himoff Machine Co., New York City, and is made with a two-step cone pulley, as shown, or a single-pulley drive.

Rotary Magnetic Chuck

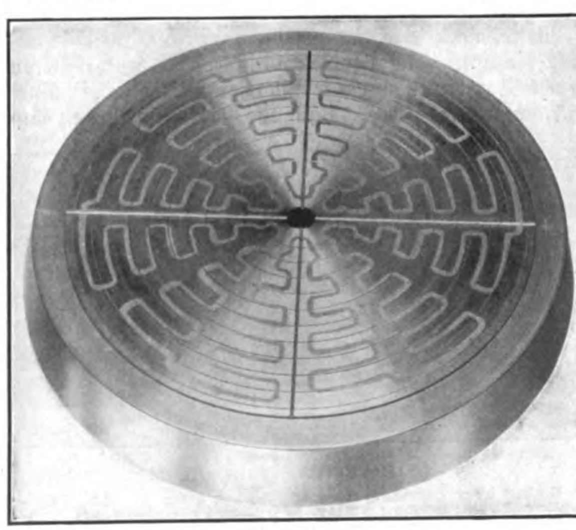
In the design and construction of the chuck shown, a recent product of the Persons-Arter Co., Worcester, Mass., the main object was to reduce to a minimum the number of air gaps between members, making a continuous magnetic circuit. This has been accomplished by reducing the number of principal parts in the circuit to three—the body or shell, the core or center and the yoke or base plate. This construction reduces the number of possible air gaps to two—between the base plate and the body, and between the base plate and the core. Further to insure a good magnetic circuit, the contact faces between these three members are ground and bolted rigidly together by soft-iron capscrews. There are only two poles in the chuck, the space between the pole faces being filled with a nonmagnetic composition of bismuth, antimony and lead having the characteristic of expanding when cooling, consequently establishing an air-tight joint between the poles.

The three members constituting the magnetic circuit are made of cast magnetic steel. Their cross-sectional area is exceptionally large, making it possible for an extremely large number of magnetic lines of force to be induced.

Although only one magnetizing coil is necessary for one particular voltage, it has been found advantageous to provide two coils. The voltage commonly used on such a coil is 110, but many firms are using a voltage of 220. With two coils it becomes a simple operation to connect to either a 110-volt or a 220-volt circuit; thus the coils are connected in parallel on a 110-volt circuit and in series on a 220-volt circuit.

The coils, after being wound and thoroughly covered with strong insulating material, are dipped in insulating compound and made waterproof. In making the electrical connections the leads from the coils run along a channel in the base plate and through an insulating bushing to the collector rings, to which they are directly soldered, thus making a positive connection and eliminating any chance of trouble due to loose connections. The collector rings are in the same plane—a feature that considerably simplifies the brush mounting. The brushes, of copper-coated carbon and mounted on hard spring brass strips, press underneath the rings and not the side, facilitating the removal and the replacing of the chuck without altering the adjustment of the brushes. The collector rings are mounted on a Bakelite-Micarta ring of substantial proportions, which is rigidly bolted to the chuck base plate. Before the assembly of the chuck is completed, all open space is filled with an insulating compound as an extra precaution against moisture, etc.

It has been observed that if two magnets are made of the same material, with the same sectional area and the same magnetizing force, but are of different shapes (for instance, one a solid circular section and the other shaped like a cross or having its surface broken up so as to present numerous edges), the one presenting the greater number of edges will show a decidedly greater pull in pounds per square inch. The chuck face illustrated consists of two series of arms—one series radiating from the center and the other radiating toward the center. Each arm carries a series of arms running concentrically, those of one pole interposed between those of the other pole, thus breaking up the face of the chuck into a



ROTARY MAGNETIC CHUCK

maximum number of parts. In order to effect a good holding power, especially needed on small parts, it is necessary to cross two poles, the part to be ground thus acting as a keeper. The concentric arms are staggered in relation to each other. This feature also assists in holding very narrow rings.

The whole surface of this chuck is magnetically alive, from the center to the edge, with the exception of the metal filling composition.

It has been found in some cases that magnetism has been transmitted to the machine by having the body of the chucks alive, but the advantage of being able to utilize the whole surface of the chuck is so great that some method had to be devised to overcome this objection. The desired effect is accomplished by introducing a nonmagnetic plate between the chuck base plate and the faceplate attached to the chuck spindle, thus blocking any stray lines that might otherwise pass to the machine.

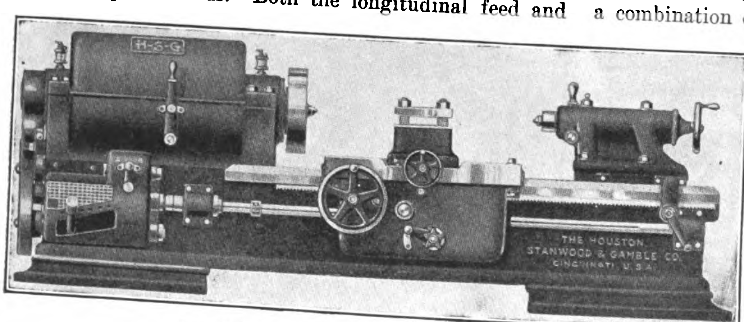
By using high-grade magnet steel, residual magnetism is eliminated; but where the work has itself become magnetized, it is necessary to demagnetize it before removal. For this purpose the chuck is provided with a special demagnetizing switch.

The removal of very thin disks after grinding is sometimes difficult, even after demagnetizing, owing to a vacuum or moisture suction between the bottom of the disk and the face of the chuck. To overcome this, the chuck has two grooves cut across its face at right angles, about 1/8 in. wide and 1/16 in. deep, enabling the introduction of a pointed instrument under the disk to lift it from the chuck face.

Heavy-Pattern Lathe with Geared Headstock

The heavy-pattern high-powered lathe shown is equipped with an all-geared headstock, having single pulley drive. The spindle bearings are bronze bushed, and steel gears are used throughout.

The tailstock is of the offset type, with adjustable set-over feature. The double-wall apron is worm driven by a feed rod with single friction control for longitudinal and cross-power feeds. Both the longitudinal feed and the crossfeed are reversed in the apron, an automatic stop for the longitudinal feed being provided. The quick-change feed has tumbler and a cone of gears with compounding arrangement within the feed box and an interchange of two gears on the end of the headstock. The gear box is driven through gears at the head of the lathe, there being a reverse plate and quadrant designed to provide a wide range of feeds.



HEAVY PATTERN ALL-GEARED LATHE

Swing over carriage, 30½ in.; swing over bridge, 19 in.; distance between centers, 72 in.; driving pulley, 19½x7 in.; ratio of gearing in head, 30 to 1 and 22½ to 1; hole through spindle, 2½ in.; length of carriage on bed, 44 in.; width of carriage bridge, 16 in.; feeds per inch, 4 to 56; length of bed, 13 ft.; weight, 13,000 lb.

The lathe is a recent product of Houston, Stanwood & Gamble, Cincinnati, Ohio.

Elevating Shop Truck

The illustration shows an elevating shop truck recently developed by the Lewis-Shepard Co., Boston, Mass., and featured by its all-steel construction, except for the wheels, which are made of gray iron.

The truck raises and lowers loads vertically, the lift ranging from 2½ to 3 in., depending upon the size. The vertical elevation is designed to conserve floor space, as it permits the loaded platforms to be placed close against each other. A free lifting and steering handle is provided by using a universal joint. The elevating mechanism may be operated by the handle, no matter in what position the latter may be. The lift is accomplished by a combination of positive leverages through which, it is claimed, only 7 per cent. of the power applied is lost by friction. This makes it possible to lift 3,000 lb. with only an 85-lb. pull in four short strokes and to lift 5,500 lb. with only a 110-lb. pull in six short strokes of the handle.

ELEVATING SHOP TRANSFER TRUCK

A positive release check, controlled by a pedal conveniently located on the front of the truck, permits a slow and jarless lowering of the load. The release check stands in a vertical position, rendering the possibility of leakage at the piston end remote and preventing buckling of the plunger.

In hanging the handle 16 in. above the floor it is designed to eliminate the waste of any of the strength applied to the pull. The strong front arch is also designed to steady the load.

This form of truck is made in a variety of sizes for different capacities.

NEW PUBLICATIONS

THE "MECHANICAL WORLD" ELECTRICAL POCKET BOOK FOR 1916—Two hundred and forty 4x6-in. pages; 129 illustrations; indexed; cloth bound. The Norman Remington Co., Baltimore, Md. Price, 30c.

This book in preparation for this years' edition has undergone revision, and matter dealing with switch gears and switchboards, earthing, reductors for half-watt lighting and the efficiency of direct-current dynamos and motors has been added. The sections on lighting circuits and switching, electric lamps and lighting have also been rewritten and brought up to date.

MECHANICAL ENGINEERS' POCKET BOOK—By William Kent. One thousand five hundred and twenty-six pages, 4x6¾ in. Published by John Wiley & Sons, Inc., New York City Price, $5 net.

To one who had the privilege of reviewing the first edition of this now famous pocket book it is particularly gratifying to see the growth both in its contents and in the number of editions printed. The changes in industry since the previous edition are indicated by the necessity of making alterations in over 400 pages and by the addition of over 150 pages of new material to bring it up to date.

It is difficult to enumerate the changes and additions made, the new tables, the condensation of matter to prevent making an unwieldy volume or, in fact, to do justice to such a book in any review without taking up each section in detail, which seems unnecessary with such a well-known volume. The revision, by William Kent and his son Robert Thurston Kent, is in keeping with the standards set by previous editions.

CORROSION OF IRON—By L. C. Wilson. One hundred and sixty-nine pages, 5x7½ in.; cloth bound; indexed. Price, $2. Published by the Engineering Magazine Co., New York City.

This book is the result of collecting and putting in handy reference form some of the facts connected with the corrosion of iron and its protection. The volume is divided into the following chapters: The Rust Problem, Theories of Corrosion, Protective Measures, Paint Materials, Protective Paint, Influence of Different Elements on the Corrosion of Iron, Corrosion of Wrought-Iron and Steel Pipe.

In the first chapter the question of rust is discussed at some length, and how it affects iron under various conditions is explained. The various theories to account for this corrosion are considered in detail in the second chapter.

The following chapters take up and describe various protective measures, and their success in preventing rust. This book should prove useful to machine-tool builders and to anyone to whom the preventing of rust is of vital importance.

Straight and Taper Forced and Shrunk Fits--Erratum

The captions of Figs. 1 and 2 of the discussion by W. Knight, which appeared on page 733, were inadvertently transposed. The chart, Fig. 1, therefore, applies to a cast-iron shaft and the second chart to a steel shaft.

PERSONALS

G. W. Helpman has been appointed superintendent of the Defiance Machine Works, Defiance, Ohio.

Oskar Kylin, for six years with the Warner & Swasey Co., Cleveland, Ohio, for the most part of which he acted in the capacity of designer, has accepted a position with the Foster Machine Co., Elkhart, Ind.

Joseph A. Horne, for more than 24 years associated with the Yale & Towne Mfg. Co., acting in the capacity of general superintendent in recent years, has been elected second vice-president, still retaining his executive position in the shop.

George H. Houston, for several years production superintendent of the Root & Van Dervoort Engineering Co., Moline, Ill., and more recently with the John Deere Co., has become associated with the American Can Co. as a member of the engineering division.

BUSINESS ITEMS

The offices of the Century Steel Co. have been transferred to the Equitable Building, New York, the warehouse remaining at 191 Pearl Street, New York.

The Independent Pneumatic Tool Company's Atlanta Georgia Branch was moved to Birmingham, Alabama on May first. A suite of offices have been leased in the Jefferson County Bank Building.

The Doehler Die-Casting Co., of Brooklyn, New York, and Toledo, Ohio has acquired a controlling interest in the American Die Casting Co., of Newark, N. J., which will hereafter be known as the Doehler Die-Casting Co., of New Jersey. Its present management remains unchanged.

Ingersoll-Rand Co., 11 Broadway, New York. Form No. 3029. Ingersoll-Rogler Class ORC duplex Corliss steam driven air compressors. Illustrated, 32 pp., 6x9 in. Form No. 3036. Turbo blowers. Illustrated, 10 pp., 6x9 in.

FORTHCOMING MEETINGS

Master Car Builders' Association. Annual meeting, June 14-17, Atlantic City, N. J. Joseph W. Taylor, secretary, Karpen Building, Chicago, Ill.

American Railway Master Mechanics' Association. Annual meeting, June 17-21, Atlantic City, N. J. Joseph W. Taylor, secretary, Karpen Building, Chicago, Ill.

American Society for Testing Materials. Annual meeting June 27 to July 1, 1916, Hotel Traymore, Atlantic City, N. J. Edgar Warburg, secretary, University of Pennsylvania, Philadelphia, Penn.

American Society of Mechanical Engineers. Monthly meeting first Tuesday. Calvin W. Rice, secretary, 29 West Thirty-ninth St., New York City.

Boston Branch National Metal Trades Association. Monthly meeting on first Wednesday of each month, Young's Hotel. W. W. Poole, secretary, 40 Central St., Boston, Mass.

Providence Association of Mechanical Engineers. Monthly meeting fourth Wednesday each month. J. A. Brooks, secretary, Brown University, Providence, R. I.

New England Foundrymen's Association. Regular meeting second Wednesday of each month. Exchange Club, Boston, Mass. Fred F. Stockwell, 205 Broadway, Cambridgeport, Mass.

Engineers' Society of Western Pennsylvania. Monthly meeting third Tuesday; section meeting, first Tuesday. Elmer K. Hiles, secretary, Oliver Building, Pittsburgh, Penn.

Rochester Society of Technical Draftsmen. Monthly meeting, last Thursday. O. L. Angevine, Jr., secretary, 857 Genesee St., Rochester, N. Y.

Superintendents' and Foremen's Club of Cleveland. Monthly meeting third Saturday. Philip Frankel, secretary, 310 New England Building, Cleveland, Ohio.

Western Society of Engineers, Chicago, Ill. Regular meeting first Wednesday evening of each month, excepting July and August. J. H. Warder, secretary, 1785 Monadnock Block, Chicago, Ill.

Philadelphia Foundrymen's Association. Meetings first Wednesday of each month. Manufacturers' Club, Philadelphia, Penn. Howard Evans, secretary, Pier 45 North, Philadelphia, Penn.

Technical League of America. Regular meeting second Friday of each month. Oscar S. Teale, secretary, 35 Broadway, New York, N. Y.

Prices--Materials and Supplies

IRON AND STEEL

Pig Iron—Quotations were current as follows at the points and dates indicated:

	May 5, 1916	One Month Ago	One Year Ago
No. 2 Southern Foundry, Birmingham	$15.00	$15.00	$9.50
No. 2 X Northern Foundry, New York	20.75	20.50	14.00
No. 2 Northern Foundry, Chicago	19.00	19.00	13.00
Bessemer, Pittsburgh	21.95	21.95	14.55

National Defense and International Peace

Are You Ready to Play Your Part?

THE power of a nation in time of need is the producing power of her industries.

America must find out what this producing power is and then develop it. The capacity of every plant must be gauged. The ability of every man must be known. For War is Mechanical. It is Electrical. It is Chemical. It is Mining, Manufacturing, Transportation. It is EVERY phase of Engineering fused into a single industry—

"THE NATION'S DEFENSE"

Thirty thousand Engineers and Chemists today are serving YOUR COUNTRY without pay. They are making a survey of YOUR COUNTRY'S Industrial Resources. They are helping YOUR COUNTRY to FIND ITSELF—and You! They are charting the channels of commerce. Sounding each source of supply. So that, *should* the Day break when War *must* come—

YOUR ARMIES in the field will be but the crest of a Wave of Industry, as wide as the American Continent and as deep as the American Soul.

That YOUR COUNTRY may know what the Engineers and Chemists are doing, the Associated Advertising Clubs of the World have pledged their services to the President of the United States. And this advertisement, published by the American Machinist, free, is part of a nation-wide series to secure YOUR cooperation.

"WHAT CAN I DO?"

This is, doubtless, the question you are asking yourself. Here is the answer: If you are a manufacturer cooperate fully with the Engineers and Chemists so they can do their job *quickly and efficiently*; if you are a mechanic help your employer to help the Engineers and Chemists and be prepared, if so needed, to be a Soldier of Industry, behind the firing line, which is just as important as being a soldier on the firing line; if you are a business man or a professional man, or whoever you are, help mobilize "GOOD WILL" behind this patriotic task of the Engineers and Chemists in behalf of National Defense and International Peace.

Manufacture of Cartridge Brass*

By C. R. Barton

SYNOPSIS—The manufacture of cartridge brass has so long been kept secret that those interested will welcome this article at a time when this commodity is in such demand. The entire process of making cartridge brass—from the mixing to shearing the cast ingots—is given, together with the furnaces and tools, in detail.

The demand for cartridge brass during the past year has increased more rapidly than the means for its production. A number of firms not directly engaged in this class of work have installed equipment for making brass, in some instances building their own machines on account of the very long deliveries promised for nearly all classes of brass-working machinery. It is proposed to describe the methods and tools used in the production of finished bars of brass suitable for making blanks for cartridge cases. The author is not an experienced brass manufacturer, and concerning matters of technical details where practice may vary it is the intent to describe a proved method for turning out cartridge brass rather than completely outline the art of brass making. It is greatly to be regretted that brass makers still endeavor to maintain a medieval policy of secrecy in their work, which doubtless has much to do with the slow progress made in overcoming some of the difficulties in producing brass of uniformly good quality with small losses.

1. The specifications usually require either pure electrolytic or pure Lake copper and "Horsehead" spelter or its equivalent. Equally good results have been obtained using a spelter of not quite as high a grade as Horsehead. The maximum allowable impurities in good spelter should be: Lead, 0.30 per cent.; iron 0.04 per cent.; cadmium, 0.20 per cent.; and total, not over 0.25 per cent. In the copper the total impurities should not exceed 0.03 per cent. These are analyses which include all grades of copper and spelter suitable for cartridge brass and represent an average of materials supplied on recent orders.

2. A specification may be made covering the quality and maximum weight of scrap that may be used in the mixture for melting. This allowance runs from 50 to 65 per cent. of scrap brass, which may consist of scrap from the blanking press, overhauling machines and shears, the point being to eliminate foreign scrap, skimmings or scrap from the floor and mold pits, which may contain dirt and other impurities.

3. The right is reserved for inspectors for the purchaser to take samples and make chemical analysis of metals in stock, to check for conformity with specifications.

4. Chemical analysis of the finished metal ordinarily allows a variation of plus or minus 2 per cent. in the specified copper content, the proportions being usually 67 per cent. copper and 33 per cent. zinc up to 71 per cent. copper and 29 per cent. zinc. The total impurities permitted in the finished metal vary from 0.2 per cent. to 0.4 per cent., with the additional requirement that arsenic, antimony, phosphorus and cadmium must be kept within a minimum of from 0.04 to 0.08 per cent. In actual practice we have found that the foregoing limits of plus or minus 2 per cent. are fair and are about as good as may be secured with the average class of workmen. The average of 156 mill analyses running on metal 69 to 73 per cent. copper was 70.93 per cent., with six above 73 per cent. (the maximum being 78.6 per cent.) and seven below 69 per cent. (the minimum being 67.69 per cent.). In no analysis did the total impurities exceed 0.15 per cent., nor was there the least trace of arsenic, antimony or cadmium. There was a slight trace of phosphorus, which came from the phosphorized copper used as a flux.

5. Physical tests for finished metal are for breaking load and elongation. The requirements run from 40,000 to 44,000 lb. per sq.in. minimum breaking load, with a maximum sometimes specified between 48,000 and 50,000 lb. per sq.in. The minimum elongation required varies from 50 to 62 per cent.; but there is no standardized test piece used, so that these tests are not comparative. In addition, sometimes a formula for a combination of breaking load and elongation is specified, so that both minima may not occur at the same time. The pieces used for these tests are cut from blanks ready for ship-

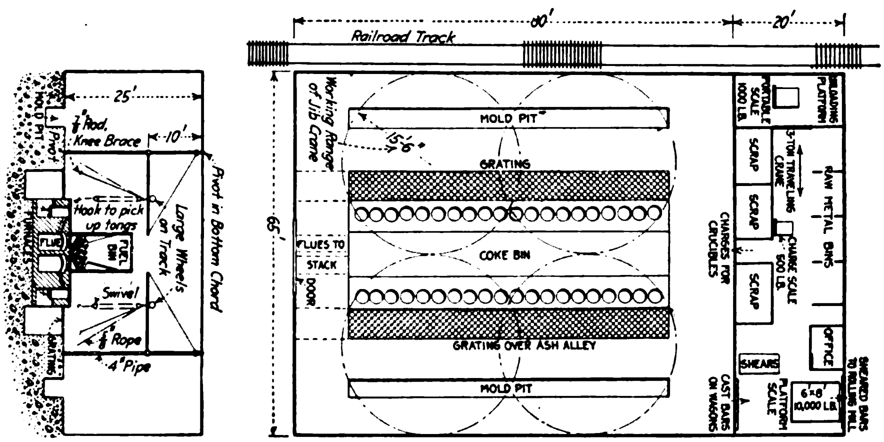

FIG. 1. PLAN AND SECTION OF CASTING SHOP

ment and have been annealed in the bar previous to being blanked. A cupping test is usually specified and is desirable, as it shows the temper of the metal and so checks its suitability for the first drawing operation without reannealing, as that is not absolutely determined by the elongation test previously described.

6. The variations permitted in dimensions of the finished blanks vary from plus or minus 0.005 in. to plus or minus 0.015 in. in diameter. The allowance in thickness varies from plus or minus 0.003 in. to plus or minus 0.007 in. Where close limits are required, it is usually because the disks are sold by weight and the purchaser wishes to keep poundage down as low as possible, as otherwise the manufacturer would furnish disks of approximately the maximum dimensions.

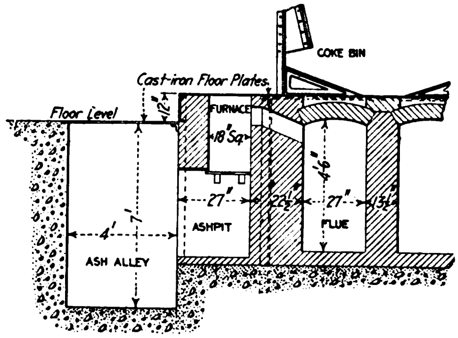

FIG. 2. TYPICAL SQUARE PIT CRUCIBLE FURNACE

7. The visual examination is one of the most important points of inspection. The disks are inspected for flaws, folding cracks and other defects in the surface and for pipes and cracks in the edge of the blank. This inspection is most important, and upon it usually 99 per cent. of all rejections are made.

8. Of the several methods of inspection probably 100 per cent. inspection is the best and fairest to both manufacturer and purchaser. As the metal is made in small lots at a time, there is not a condition of uniformity in manufacture which would warrant a partial or percentage inspection. Also, when the latter scheme is used, the inspectors require a lower proportion of rejected disks in the lot selected than the average on total inspection, so that usually it is necessary to return to total inspection.

9. Aside from the foregoing items various other clauses are inserted in the specifications by the purchaser's covering number of rehandlings allowed on rejected materials, size of lots submitted for inspection, microphotography and the manufacture of selected disks into cartridge cases for the development of interior flaws or defects not shown by visual examination.

As with all inspection where the most important point is visual examination, which is entirely dependent upon the judgment of the inspector, there is a possibility for considerable variation in opinion as to the extent and seriousness of defects. For this reason no hard and fast rule can be laid down as to what constitutes fair visual inspection. Where the inspection is done by a third party regularly engaged in inspection work, better results may be obtained than from inspection by the purchaser direct, whose judgment is based on personal opinions rather than experience as to the extent of defects that may be passed.

That division of the plant where the brass is melted and cast is usually termed the casting shop. This department covers all work from receipt and storage of copper and spelter up to the delivery of sheared bars to the rolling department. All the work may be carried on in one large room with suitable space partitioned off for a metal-storage and weighing room, hereafter called the scraproom. The usual construction is a steel-frame mill building about 25 ft. high to the bottom chord, so designed as to give maximum ventilation. The two main points to be considered in locating the casting shop are car sidings convenient for unloading metal for the scraproom and full and ample storage for fuel and ashes. As the sheared bars are handled on wagons, the location relative to the rolling mill is not so important as long as it is within a convenient distance for hauling.

Fig. 1 shows a floor plan of furnaces, ash alleys and mold pits for a typical installation. As the plant described was built for making cartridge brass in short bars, the pits are only 3 ft. 4 in. deep. In plants where the usual variety of rolled and drawn brass is handled, deeper pits, up to 10 ft. for casting bars up to 12 ft. long, are used. The unit of equipment is known as a set of fires, generally consisting of 10 furnaces and the necessary auxiliary equipment for the complete operation for casting bars. Each set of fires is handled by one caster and his helpers. The jib crane shown is for lifting the pots from the furnace and carrying them over the molds in the mold pits. The jib crane should be of such length that it can take in the extreme molds of each set of fires without greatly interfering with the adjoining set of fires. The space occupied by each set of fires is equal to that of 10 furnaces, the molds that can be filled by the output of the fires not taking a greater length of space in the mold pit. The size of the furnace is determined by the maximum size of the crucible used, the selection of which is covered under the discussion of crucibles. Assuming that the No. 90 crucible which is 13⅜ in. in diameter outside will be the largest size, and that we design our furnaces for coke as fuel, which re-

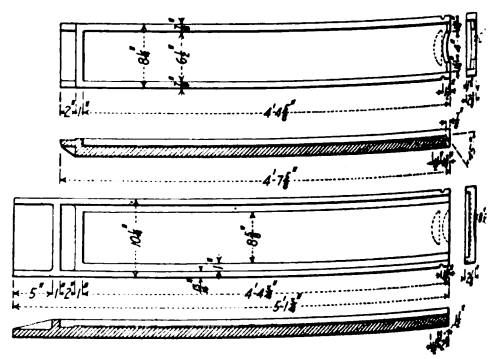

FIG. 3. MOLD FRONT AND BACK

quires the greatest space, say 5 in., and that the brick wall between each two furnaces must be not less than 13½ in., we have a maximum distance between centers of furnaces of 32 in.

Fig. 2 shows a larger-scale section of the furnace designed in accordance with these calculations. The furnaces are made square, as this style has a great advantage over the round furnaces in that the corners hold the fire

and permit placing the crucible tongs on the crucibles more easily. The furnace should be deep enough to provide at least 12 in. of fire beneath the bottom of the crucible, so that as the fire burns out on the grate the bottom of the crucible will not become cold. The depth should also be such that the top of the crucible is always below the bottom of the flue opening, in order to have all parts of the crucible subjected to an even heat. The furnace should be bricked up so that but one course of brick around the inside need be removed when the furnaces are relined, putting in only enough tie-bricks to the second course to hold the lining. The life of the lining varies greatly with the fuel used, coke making a much hotter fire than coal. Operating two shifts for four months made relining necessary on furnaces burning coke. The quality of firebrick and fuel must be considered as in other furnace work. The grate bars are 1 in. square, set on two bearers, such as a piece of 60-lb. rail. The draft may be natural or induced. A forced-draft system does not give satisfaction, as it rarely balances, thus throwing out into the room intense heat, which becomes a serious consideration in hot weather.

The ash alley should be of a cross-section that will allow easy passage of a wheelbarrow for removing the ashes when cleaning the fires. The coke bin, as shown, should provide storage for at least two days' requirements, and the monorail trolley is probably the simplest means for filling the bin from outside storage.

The quickest fire is not always the most desirable in the long run. Using a special 21-in. square furnace, we have been able to take out 21 heats in 24 hr., including cleaning fires twice. This is during cold weather; but it is doubtful if it is economical, as men cannot be secured readily who will stand up to such work, and the life of the crucible is greatly reduced. We believe 14 and possibly 15 heats per 24 hr. in winter a good production, falling off to 10 or 12 in warm weather. The men employed are not, as a rule, steady workmen, so that production is not a matter of simple arithmetic only.

There are other styles of furnaces, such as reverberatory furnaces, the Schwartz furnace and the type known as

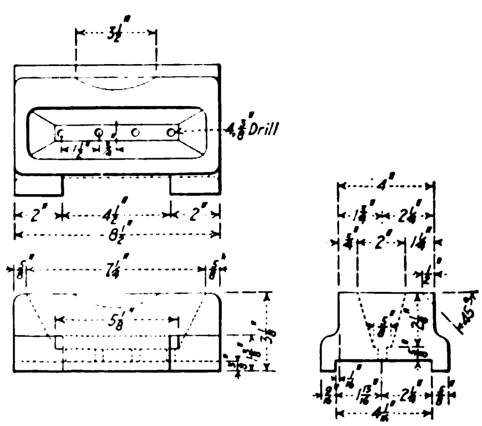

FIG. 4. MOLD STRAINER

the tilting furnace, in which the crucible is tilted for pouring. In all these a distributing ladle must be used, which means a second pouring of the metal. Repeated installations of the old-style crucible furnace, replacing some of the foregoing, show that for certain classes of work it is still the best in spite of the crucible expense.

Of late there has been considerable experimenting with various kinds of fuel. The plant here discussed is laid out for burning coke or coke and coal. Where maximum production is demanded, that method is most efficient which will enable the greatest number of heats to be obtained from one furnace in a given time. Hard coal

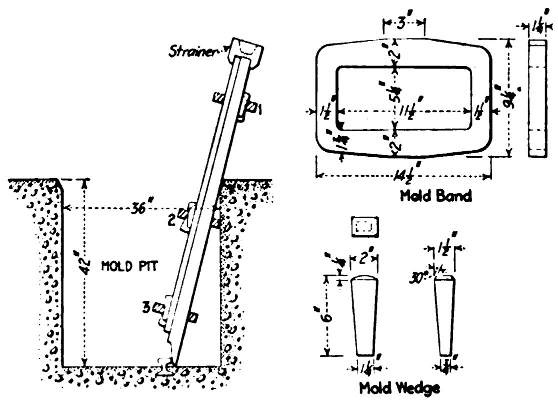

FIG. 5. MOLD BANDED FOR POURING

is probably the slowest fuel used, and the length of time required for getting out a heat is the only objection to it, as in other respects it is very satisfactory. Coke gives a much hotter and therefor faster fire, with a greatly increased wear on the furnace lining. Both oil and natural gas would seem to be desirable. The author has not had experience with oil-fired furnaces. Twenty of the furnaces shown in Fig. 1 were equipped for burning natural gas, using forced draft. Different methods for venting the furnaces were tried, but without great success. The heat from the furnaces was such that the cover brick became red hot and conditions were made intolerable for the workmen. We do not believe that the gas fuel was given a thorough trial, as it is no doubt the ideal fuel for crucible furnaces and will prove successful as soon as it has been put through an experimental stage in a large plant, where furnaces are necessarily set close together.

The fuel consumption varies with the rate of production and the size of the crucible furnace. No exact data can be given; the most reliable figures indicate from 0.4 to 0.6 lb. of coke and coal (mixed) per pound of metal melted during a period of several months, with 18-in. round and 21-in. square furnaces.

The molds for the cartridge brass may be seen in Fig. 3. They are made of gray iron containing 2.5 silicon and finished as shown. The size of the mold is determined by the width of bar required and the weight, which should be such that one pot of metal will make full-length bars. For convenience in handling, the bars are usually made from 80 to 125 lb., unless the size of the finished bar or sheet requires more metal. In rolling, the metal flows almost entirely in the direction of the rolls, so that if bars are passed through straight, there is no appreciable widening. Bars are cast in regular work up to 15 in. wide in short bars and up to 10 and 12 ft. long in narrow bars. It is always best to cast the bar of a thickness that will avoid as much rolling as possible, and the ⅞-in. thick bar is now about standard size, although 1¼-in. bars are made at times.

The molds should be planed on the joint. Otherwise they will be strained in banding, as the wedges tend to

straighten out the molds, which rarely come exactly straight from the foundry, and thereby produce stresses that will soon crack either the front or the back of the mold. Also, with unplaned molds the leakage is many times that of the planed type. Another advantage is that the bars come clean and of even thickness. Some experiments with molds planed all over inside have been made by other firms in an effort to insure cast bars more uniformly good, but without favorable result. The molds shown are of very heavy section, but the weight may be cut down as soon as the most economical form is determined. In making rolled rods bars are cast 1½ in. in diameter and upward in solid bored cast-iron molds. The iron must be free from blow-holes and other flaws.

An important adjunct of the mold is the strainer, Fig. 4. In pouring, the strainer should be kept full, so that the slag and dirt passing the skimmer will not enter the mold.

The mold is held together, as illustrated in Fig. 5, by three bands wedged up tightly. The bands and wedges should be made of first-quality cast steel, if the use of expensive forged pieces is to be avoided. The order and manner of driving the wedge are shown by the numbers. This method has been found to reduce leakage.

The life of a mold is very uncertain. Some few foundries make a specialty of ingot molds, and their product has a high reputation. One of the largest brass makers in this country, after some years of experiment and experience, found that the molds of one firm gave uniformly 50 per cent. longer life than any other make. Molds should average at least 2,000 to 2,500 heats.

The several kinds of tongs may be seen in Fig. 6. All are made of wrought iron by the blacksmith shop in the plant. The most important are the crucible tongs for handling the crucibles. In forging, these tongs should be shaped to a cast-iron crucible of the same size as that to be used. Tongs should always be refitted whenever there is a change in either the make or the size of the crucible. Ill-fitting tongs injure the crucibles and may cause a loss many times the value of several sets of tongs. When worn and burned out of shape, the bits should be redressed or cut off and new ones welded to the reins.

Other tongs are spelter tongs for dipping the spelter in the molten copper, mold tongs for lifting the fronts and backs of molds, band tongs for handling the hot bands, stirring-rod tongs for holding the graphite stirring rods, and bar tongs for lifting the hot bars from the pit when the molds are stripped. These different kinds are illustrated in Fig. 6, and the weights, number required and other data are given in the table.

The remaining equipment includes skimmers for skimming the pot when it is lifted from the fire and for holding back slag and charcoal that is not removed by skimming when pouring, scrapers for scraping the molds, wire brushes for cleaning molds after scraping, heavy buckets for mold dressing, powdered charcoal and flux, cheap 4-in. flat brushes for applying mold dressing, sledges, hammers, etc. Some of these tools may be seen in Fig. 6, and other data are given in the table. In most cases two sets of tools are allowed for each set of fires, as the tongs become too hot to be comfortably handled if used continuously.

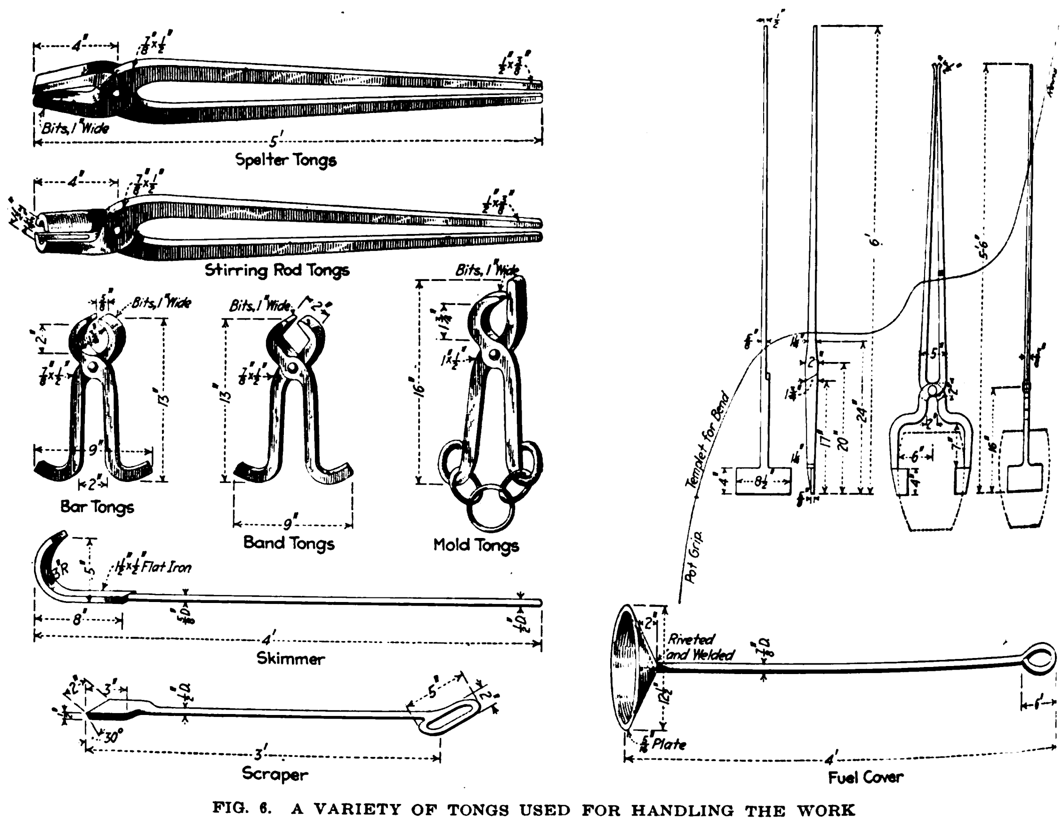

FIG. 6. A VARIETY OF TONGS USED FOR HANDLING THE WORK

In the table the probable life is given in heats. The author has not enough data at hand to give more authentic figures.

Crucibles are, aside from losses, the greatest single item in the cost of producing brass. For this reason many attempts have been made to get away from the use of crucibles. Long experience in crucible making shows that the best materials are Ceylon graphite and Klingenberg crown clay. Ceylon graphite is free from mica and is about 98 per cent. pure. The Klingenberg clay comes from a small district around the village of that name in Germany. These materials are blended and mixed in proper proportions, molded, dried and burned in a kiln. The amount of excess air in the kiln determines whether or not the graphite is burned out of the surface of the crucible, thus making the white or blue crucible. Obviously, the matter of color is of no importance, although manufacturers are called upon to supply crucibles of a given color. Crucibles usually contain from 50 to 60 per cent. of graphite.

Crucibles are known by number, each unit in the number representing nominally the capacity to hold 3 lb. of molten metal. Therefore, a No. 90 should hold 270 lb. of brass. About 80 to 90 per cent. of the capacity of the crucible may be used, depending on the care of the caster.

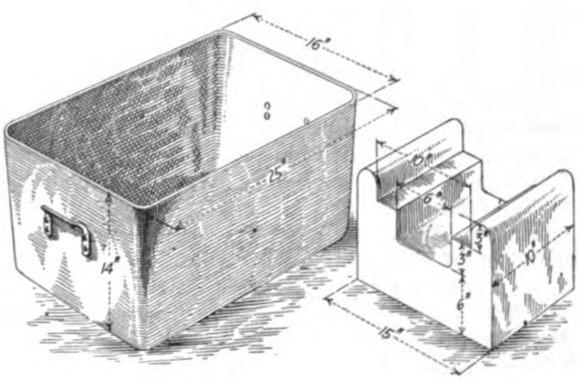

FIG. 7. TOTE BOX AND SPELTER-BREAKING BLOCK

A year ago crucibles containing the best material sold for from 5 to 7c. per unit in the number. At the present time, owing to the high value of Ceylon graphite, the prices are 11 to 13c. per unit; and as the makers have only American clay to use, they expect only 8 to 10 heats per crucible. The average life of 1,500 crucibles purchased in July, 1915, was about 18 heats, so that the actual cost per heat has quadrupled. Manufacturers claim that their crucibles average 25 heats, and doubtless this figure may be attained with the best materials.

The life of a crucible is shortened by ill-fitting tongs, as previously stated, by excess fluxes of various kinds, by soaking in the fire longer than necessary to melt the metal, by too high furnace temperatures in the endeavor to get quick heats, by wet or sulphurous fuels that attack the outside of the crucible, by carelessness in stirring the metal and by general lack of care in handling.

In the employment of fluxes such as fluorspar and various silicates a mean must be determined so that the metal will be purified with a minimum erosion of the crucible. The crucibles should be thoroughly dried and annealed for two of three weeks before being put into service. This is frequently done by storing them on a floor on top of the muffle furnaces used for annealing in the rolling mill. A careful record of the size and number of crucibles given to the casters should be kept.

The best size of crucible has been found by long practice to be the No. 80, holding a charge of 200 to 220 lb. of brass. This crucible makes two bars of convenient size in narrow metal or one in wide metal. It seems to have a somewhat longer life than larger crucibles and therefore, striking a mean between labor and crucible expense, gives the lowest cost of production. There is much juggling of sizes, and many makers rate their crucibles above standard, so that buyers should compare cubic contents and weights rather than size numbers.

There are several compounds on the market for applying to the crucible as a paint. Some report these materials to be of value. Broken crucibles should be placed in bins, and in spare time, laborers may be set to work chipping off the inside surface, which may have some metal adhering to it. The latter is reclaimed with the ashes. The old crucible material commands a market price of from $10 to $15 per ton.

Probably no subject in brass making has received as much attention as fluxes. And when all has been said, brass makers are still employing the same fluxes with or without their potent secret additions. For clean scrap and new metals such as must be provided in making cartridge brass, phosphorus and common salt seem to give the best results. The phosphorus is in the form of 15 per cent. phosphorized copper, 1 oz. per 100 lb. of metal. A larger quantity may be used if needed, but not enough to give a perceptible amount of phosphorus in the finished metal. Common salt, somewhat finer than crude rock salt, should be added, about one handful per 100 lb. of metal. Care should be taken to avoid an excess, as this attacks the crucible.

The impurities to be removed are mainly copper oxide, sand and dirt. The foreign metals—tin, iron and lead—cannot be removed, and none should be introduced by iron stirring rods, brass scrap containing lead, etc. The copper oxide forms readily, and for this reason the melting metals should be covered with powdered charcoal to prevent oxidation. Patent fluxes are generally in the identical class with medicines of the same description.

The metal-storage room, also known as the scraproom and weighing room, is one of the most important parts of the brass-manufacturing plant. Here the new metals are received and stored, all scrap is received and weighed, and the charges for each heat are weighed up in correct proportions. The plan, Fig. 1, gives the arrangement at the plant described. The room contains bins for the various grades of scrap, keeping clean metal, floor scrap and the recovered metal apart; space for storing bars of copper and spelter; a four-bar scale for weighing the charges; a platform scale for weighing metals received and the cast bars on wagons before and after shearing; and a powerful lever shear for cutting new metal and cast bars. As the records of this work are very important, a small office should be provided so that the foreman may keep his records neatly and accurately. The scales for weighing the charges are set by the chemist and should be kept under lock. The charges are weighed up in small iron pans illustrated in Fig. 7.

The cast bars are brought in in a wagon and weighed on the platform scales. The heads or gates of the bars

are then cut off in the shears and the bar cropped back until the cross-section shows good metal without pipes or other defects. It is important that a skilled man of excellent judgment have charge of the shears, as much good metal may be cut off as scrap if the bar is cut back too far. Likewise, a large amount of work is wasted and the percentage of scrap in the finished product increased if the bar is not cut back far enough. The color of the sheared section will indicate relatively small variations in the copper and zinc content, so that the experienced shearman will recognize bars that are outside the specified limits and cut them up. A bar that is cut to much less than half its length should be cut up, as it is probable that it has objectionable defects not visible. It also gives trouble in handling and rolling. The shears should be powerful enough to cut brass 1½x10 in. They will then be able to cut up copper ingots in suitable sizes for weighing out exactly on the charging scales. A small breaking block for spelter is also shown in Fig. 7. After the bars are sheared, they are weighed, and the caster is credited with the weight of good metal thus produced. The floor scrap—from broken pots and leakage from the mold pits—is collected once each day and weighed into the storage bin in the scraproom.

The charges weighed up in the scraproom are brought out on the casting floor and set behind each furnace, accurate record being kept of the number of boxes given each caster. The first operation, starting each day's work, is to clean the fires by pulling out the grate bars and removing the ashes, care being taken to punch out the clinker that has formed at the bottom, as this sometimes reduces the cross-section of the grate to one-third its actual size. A fresh fire is then built, which in continuous operation is usually lighted by the hot bricks in the furnace. As the fire comes up to heat, the crucible, which has been previously warmed by being on top of the furnace, is placed in the fire, and the heavier metal of the charge, except spelter, is laid carefully in the crucible, care being taken that the metal does not tend to wedge the pot apart during melting, when the pot becomes soft. Ordinarily, a ring made from the upper half of an old crucible is placed on top of the crucible to hold the scrap and copper that cannot be put inside. In this case the scrap should be put in the bottom, as it melts faster than the copper.

TABLE OF EQUIPMENT FOR ONE SET OF TEN FURNACES*

Name of Article	Number Required	Life in Heats, Each	Weight, Lb., Each	Cost, Each
Crucible tongs	2	7,000	55	$6.00

				Per Lb.
Molds	20	2,000	450	.05
Bands	60	200	25	.05
Wedges	100	3,000	5	.03
Strainers	20	Indefinite	27	.03

*The figures are approximate, as in some instances they are based on estimate only.

After all the metal is melted and up to a bright heat, the spelter, which has been warmed by lying on the furnace, is thrust beneath the surface of the metal and is rapidly melted and alloyed with the copper. The brass is then stirred thoroughly with a graphite stirring rod, so as to secure a homogeneous mixture. The graphite stirring rods are expensive, but are the best for high-grade brass, as iron from an iron stirring rod will alloy with the brass and thus increase the impurities. During the melting, salt and powdered charcoal are thrown on the metal, the charcoal to protect the molten metal from the atmosphere and the salt to act as a flux. After a vigorous stirring, the metal is given a minute or two to allow the impurities and dirt to come to the surface in the form of slag. The crucible tongs are then placed on the crucible, which is raised from the furnace by means of the jib crane. The outside surface of the crucible is cleaned, and it is then lowered on clean sand on the floor. The slag is skimmed off and a block of wood thrown on the clean surface of the metal.

The point might be made that there is the same objection to the iron skimmer as to the iron stirring rod. Actually, the amount of iron absorbed in skimming is much less, and graphite is less suited to the rougher handling. The crucible is then raised and placed over the strainer on the mold and poured, tipping the crucible forward with the tongs, keeping back the residue of slag and charcoal with the skimmer.

The block of wood in burning tends to keep the air away from the metal and is useful in reducing the amount of spelter burned out. The strainer should be kept full of metal so that the slag and dirt passing the skimmer remain on the surface and do not enter the mold. The molds should not stand slanting sidewise, as there is a possibility that impurities and gas pockets will lodge in the corner of the mold instead of coming to the surface, so that one edge of the bar may be defective for the entire length of the mold.

The molds are prepared by scraping with the scraper and brushing down thoroughly with a wire brush, after which they are painted with lard oil. Many substitutes are offered as a mold dressing, but lard oil seems to secure the best results. The molds are then banded and wedged up tight and are ready for use, the strainer being placed on top. After pouring, the metal is soon chilled sufficiently to allow the bands to be knocked off and the mold opened. The bars are raised with the bar tongs, and the burrs are filed off. Then the bars are piled on the floor behind the mold pit and allowed to cool until they can be loaded on wagons and taken to the shears in the scraproom. The molds are cleaned thoroughly and dressed with lard oil each time before being used.

The term "losses" covers the difference between the metal weighed out and melted and the total metal returned. The gross loss includes the metal in the ashes, and the net loss is that determined after the ashes have been put through the recovery plant and a large part of the metal in the ashes reclaimed. The net loss is therefore the difference between metal melted and that returned from all sources.

The melting loss varies with the type of furnace used, size of charge and proportions of mixture. On cartridge brass under the conditions outlined the gross loss varies

from 3 to 5 per cent. No figures are available for the net loss, but in other plants it varies from 1 to 3 per cent.

The loss represents a greater money value than the profit in manufacture and therefore should be given the most careful attention. An installation and working conditions which prevent metal from being lost in the fire by careless charging and by the use of worn-out crucibles and which avoid excessive volatilization of spelter by not using enough charcoal to cover the molten metal, by not overheating the metal, by pouring as soon as ready and not soaking the metal, by not using unnecessary draft, etc., will go far toward reducing this expense.

Metal spilled in handling and pouring is recovered from the mold pits and floor each day. This is known as floor scrap, and to it is added the solid metal picked from the skimmings and ashes, which contain the metal representing the difference between the gross and the net losses. No figures are available to give proportion by weight of recoverable metal in the ashes in the plant described, but it has been found by other firms to run from 0.25 to 0.5 per cent. by weight of ashes.

This recovery is made by concentrating and refining processes. The quantity of ashes is not sufficient to warrant a recovery installation in any but a large plant. The floor scrap may be melted directly with the charge in small quantities or remelted and sheared before using, as the quality of work may require. Some specifications for cartridge brass permit the use of floor scrap; and if used judiciously, no bad effects will be noticed.

In addition to the tools and equipment mentioned the following materials are required in the approximate quantities given, which are the results of several months' operation:

Coke	50 lb. per 100 lb. metal melted
Charcoal (used in lighting fires)	0.1 bu. per 100 lb. metal melted
Lard oil No. 2	0.04 gal. per 100 lb. metal melted
Salt	0.25 lb. per 100 lb. metal melted
Phosphorized copper	1 oz. per 100 lb. metal melted
Graphite stirring rods, 1½ x 18 in. long	30 heats each

For a plant having 40 furnaces, or four sets of fires, there will be required 4 casters, 16 to 20 casters' helpers and 4 laborers. These men will be able to produce from 5 to 7 heats from each furnace in about 9 hr. The casters are paid on a tonnage basis at the rate of 17 to 20c. per 100 lb. of good sheared metal. The casters pay two helpers at 65c. per round, which is one heat from each of the two furnaces comprising a set of fires. The firm supplies additional helpers at the same rate, giving three men if special circumstances require them. A better arrangement is to pay on a tonnage basis for the entire crew about as follows, per 100 lb.: Caster, 8c.; floor helpers, 5½c.; pit, 4½c.

In this scheme the bars are marked with the crew number, and a deduction is made for bars scrapped at the overhauling machines in the rolling mill, as metal apparently good at the shears may be poor metal when overhauled—that is, the process of scraping off the surface metal, dirt, etc., preparatory to rolling.

The scraproom requires about 10 men—4 on the shears and 6 on the scales. The pay of these men runs from 20 to 30c. per hr.

The direct cost for producing sheared bars ready for rolling is about ½c. per lb. of metal melted, divided about evenly among labor, supplies, renewals, etc. To this figure must be added the value of metals lost and burden. These items may vary greatly. The distribution of metals between weighed charge and sheared bars is as follows:

	Per Cent.
Metal weighed out	100.00
Net loss, volatilization, etc	2.50
Recovered metal, ashes	2.00
Floor scrap	5.00
Shear scrap	10.00
Good sheared bars	80.50

These figures represent what may be called fair to good operation, but undoubtedly offer opportunities for further economies. The importance of accurate records will be appreciated in making an estimate. Several of the most necessary are shown.

To many it might seem that the crucible-furnace method of making brass is antiquated and that units of larger capacity should be used. But segregation, gas occlusion, rehandling and consequent cooling in ladles and higher losses are still disadvantages of the large furnace that must be taken into consideration.

For rolling, the metal must be homogeneous and absolutely free from dirt. Therefore, metal molds are preferred, and the consequent chilling allows no time for impurities to rise to the top. Also, the chemical analysis must be fairly close; and as one component of the alloy is easily oxidized, the metal must be melted, poured and cooled quickly. No doubt many improvements will be introduced into brass making in the immediate future, as experimental investigation is now being taken up in earnest by many manufacturers.

Connecting-Rod Testing Fixture for Cycle Motors

By E. V. Allen

A fixture used in the shop of the Henderson Motorcycle Co., Detroit, Mich., for testing connecting-rods is here shown. The rod bearings are first reamed out; then a ground bar is thrust through the crankpin end, as at *A*, Fig. 1. The small end of the rod is placed over the end of the bar *B*. Hardened pins and stops are placed at

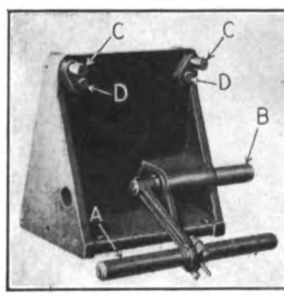

FIG. 1. CONNECTING-ROD TESTING FIXTURE

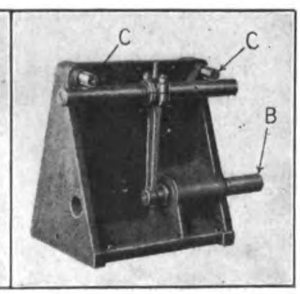

FIG. 2. ROD IN TESTING POSITION

C and *D*. The connecting-rod is swung upward against the gaging points, as in Fig. 2.

The bar *B* is eccentric, so that by turning it the rod may be raised or lowered to a certain extent. This eccentric movement makes it possible to see just how the bar in the small end lines up with the gage points. If they do not indicate true, the rod is twisted or bent until it registers correctly.

Motor-Truck Repairs in Mexico

By Hi Sibley

With 285 motor trucks now in daily service on the line of communication extending approximately 300 miles from the military base at Columbus, N. M., to the advanced front beyond Namiquipa, Mexico, and with some of the road in almost impassable condition the motor-repair shop has developed into a most important institution.

Beginning in a little tent equipped with work benches, a vise or two and the usual assortment of hand tools, it has grown to a substantial and well-equipped machine shop with concrete floor and individual power plant. The building, just erected, is of corrugated sheet iron over a 4x4 frame and is 60 ft. long by 40 ft. wide. On the eve of its completion an addition 40x40 ft. is contemplated and in all probability will be erected at once.

The present equipment includes a 20-in. Schumacher & Boye lathe with 16-ft. bed, a Smith & Mills 17-in. shaper, a 20-in. Champion drilling machine with back gears and power feed, a Buffalo forge and a Sterling No. 3 emery grinder. A miller probably will be added later. The power plant at present consists of a Stover 8-hp. gas engine, but this is to be exchanged for a larger one. The usual work benches and vises are installed, and a number of pits are built in the floor to facilitate work underneath the cars, which can be driven into the shop through the large sliding doors on both sides of the building. The doors give ready entrance and exit and make it much easier to handle the cars, as there is almost no position in the shop where a truck would be blocked by other trucks so as to prevent getting out and into service.

Considering the condition of the roads over this 300 miles through desert and mountain pass, ranging from soft and greasy adobe to heavy desert sand and rocky cañon trails, the amount of repairing required to date has been comparatively small. Apparently the damage to which all the makes of cars are most subject is tire injury from the sharp and jagged rocks in the cañons. After two round trips to the front, pieces of rubber weighing over a pound have been found in the trail of the trucks.

Occasionally there is a serious collision, due to the difficulty of driving at night without lights; then the truck is towed in by an accommodating team mate, and a general overhauling is given it. Several of the truck companies have their own repair car with two machinists in charge, and these traveling repair shops can handle anything that is not of too serious a nature. It is customary, however, to bring the disabled trucks back to the military base at Columbus whenever possible, where they may be given more thorough attention.

Green drivers, recruited on short notice from necessity, have in some cases wrought havoc with transmissions, and the principal work in progress at this writing is the replacing of broken gears. As yet no complete machine jobs have been turned out by the new shop.

Knurling in the Small Shop

By John H. Van Deventer

SYNOPSIS - This article describes the methods of making and using knurls. Cut, rolled and fancy knurls are described, and methods are given for using them on all the machines found in the small shop.

Every machinist and almost every apprentice has in his tool box one or more knurls that he is quite sure beat anything any other man ever made. Also, very good knurls in a large assortment of patterns may be bought ready to mount in a holder and use. With this prolific source of supply it may be asked why the small-shop man should be interested in knowing how to make knurls. But a small-shop man must be posted on many things that the large-shop man does not need to know, for in the course of his varied and exciting existence he rubs up against circumstances that are quite outside of his special line. And also, a knowledge of how things are made does not interfere with knowing how to employ them.

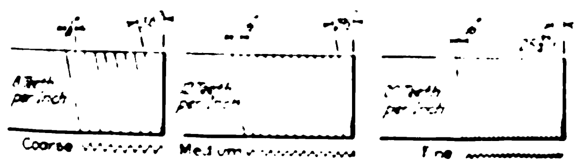

FIG. 1. ANGLES FOR CUTTING COARSE, MEDIUM AND FINE SPIRAL KNURLS

FIG. 2 ANGLES FOR TEETH

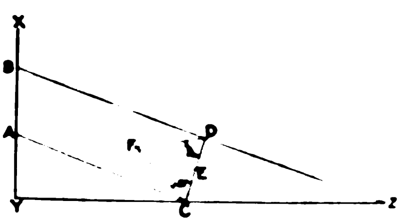

FIG. 3 OBTAINING THE DEPTH OF KNURLED TEETH

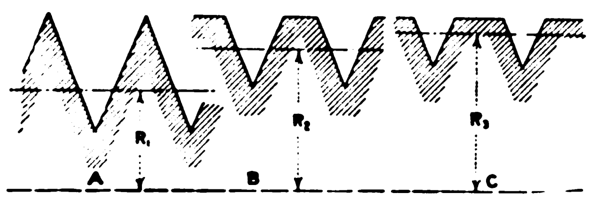

FIG. 4. VARYING THE DEPTH OF CUT GIVES SOME RANGE AS TO THE NUMBER OF TOOTH IMPRESSIONS

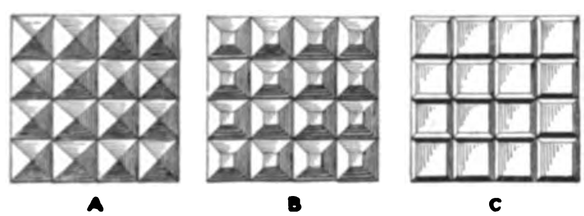

FIG. 5. PATTERNS OBTAINED WITH DIAMOND KNURLS BY VARYING THE DEPTH OF CUT

Knurling is one branch of the process by which impressions are transferred from one material to another by rolling. It is in the same class as thread rolling and the making of index dials by the rolling process. Knurling is applied to both flat and curved surfaces, and the tool itself may be either flat or curved. Where the work is flat, the knurl is circular; but when the work is circular, the knurl may be either circular or flat. An example of circular work and flat tool is the method of knurling work held in lathe centers by allowing a coarse file to "float" upon it.

I will pass up the ornamental knurls for the present and speak of the kind that will be found of greatest service in small shops—the straight and spiral patterns. These are originally produced by cutting what is known as a "master knurl." From this master, which is the same as the impression desired on the work, other knurls are produced by rolling and are used in the shop, the master being kept for reproducing purposes. Sometimes this process is carried back and forth many times, until the offspring lose their family resemblance. The great-grandchild of a master knurl will not produce as good work as his grand-daddy, and for this reason the best knurling is procured directly from machine-cut knurls without the use of masters.

The knurl has been called a "putting-on tool." It increases the diameter of the work, because metal is forced up between the knurl teeth. Knurls and thread rolls are similar in their action, knurling being simply a case of rolling multiple threads. The stock diameter increases in knurling as it does in thread milling and in both cases may be figured roughly as equal to the depth of the tooth produced, this being the same as saying that the knurl tooth goes down halfway into the stock and forces the stock halfway up into itself. The coarser the pitch of the teeth of the knurl the deeper these teeth become. The result is that more pressure must be brought against the work in order to raise the impression. For straight and spiral knurls it is well not to have less than eight teeth per inch for the coarsest pitch.

In a spiral knurl the finer the pitch the less may be the angle made with the axis of the knurl. This is shown in Fig. 1, which gives pitch and angles for coarse, medium and fine spiral knurls. The greater this spiral angle becomes the less is the "bite" taken across the face of the knurl, and it is for this reason that this angle is made greater on the coarse pitches. It also follows that a finer feed must be employed on coarse-pitch knurls than on fine-pitch ones, in order to get full tooth impressions.

The angle of the knurl tooth varies with the hardness of the material to be knurled. Various angles are illustrated in Fig. 2; they are suitable for brass, soft steel and tool steel. It also follows that the harder the material to be knurled the finer should be the pitch of the knurl, so that a sharp tooth angle and a fine pitch usually go together. This distinction, so far as hardness is concerned, is an important one.

Having the circular pitch of a spiral knurl and the number of teeth, the diameter is found by multiplying the circular pitch by the number of teeth. A simple way of obtaining the tooth depth is given in Fig. 3. XY and YG are laid out at right angles, and points A and B are laid out on line XY at a distance apart corresponding to the circular pitch of the knurl. Through these points lines AC and BG are drawn representing the teeth and making an angle with the line YZ equal to the angle of the spiral knurl. The line CB is drawn perpendicular to the line AC, and the lines CF and BF are drawn at an angle A equal to one-half of 180 deg. minus the tooth angle as shown in Fig. 2. In other words, for tool steel the angle A will be $\frac{(180 - 60)}{2} =$ 60 deg. For brass the angle A will be 45 deg. and for soft steel 55 deg. The height of the triangle thus formed, represented by the line EF, will be the tooth

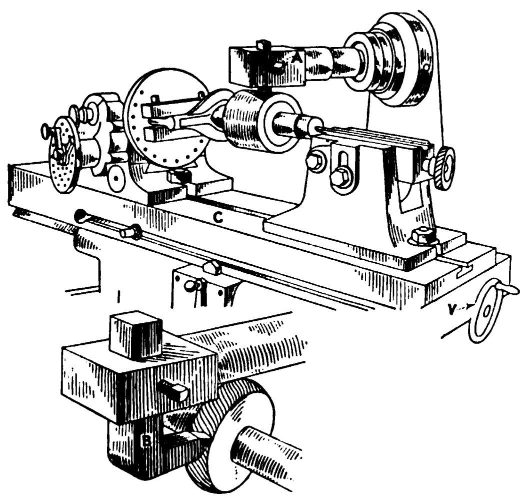

FIG. 6. A SIMPLE ARRANGEMENT FOR MAKING A SPIRAL KNURL ON THE MILLER

depth. If this diagram is laid out on paper ten times full size, the depth may be read off in thousandths of an inch by means of a scale reading in hundredths.

These calculations apply to the diameter of the knurl itself, but a similar calculation is not often necessary for the diameter of stock, although in a case of coarse-pitch knurls an attempt must be made to get the correct stock diameter to avoid tooth impressions overlapping.

This diameter may be "found" more easily than it can be "calculated." The thing to do is to leave the stock a trifle large and reduce it until the tooth impressions come out with no overlapping. On fine-tooth knurls this is not necessary, for a little more or less pressure when the knurl gets to its depth will bring satisfactory results. If you have but one piece to knurl, it is better to use a fine knurl and not have to make experiments on the diameter; but if a large number of pieces are to be knurled in the screw machine, the time spent in experimenting with one of them will not be of much importance.

Varying the depth of the cut gives a slight range as to number of tooth impressions, as shown in Fig. 4, and also produces a variation in pattern in the case of diamond knurls, as may be seen in Fig. 5. Full-depth knurling produces the pattern at A, Fig. 5, while B and C are modifications corresponding to the depths at B and C, Fig. 4. If the object of knurling is to provide a grip for the hand, as upon a chuck body, knurling to part depth is advisable, since it gives sufficient roughness to enable the piece to be gripped without having the sharpness of full-depth knurling, which is likely to hurt the hand.

Straight-tooth knurls are easily cut on a lathe by holding the blank between centers and indexing on the back gears. The tool is held horizontally in the tool post, and the carriage is moved back and forth by hand, thus planing the teeth. Spiral knurls are cut in a similar way on a universal miller having index centers. The dividing head is geared up for the correct lead of the spiral, and a single-point tool shaped to the angle of the knurled tooth is held in a fly-cutter holder such as is illustrated at A in Fig. 6. For ordinary work it is not necessary to rotate this fly-cutter; it is sufficient to hold it in a vertical position and plane the grooves by moving the table back and forth by hand, the dividing head with its gears taking care of the angular rotation of the work. When cut knurls are required in quantities, it is best to have a milling cutter.

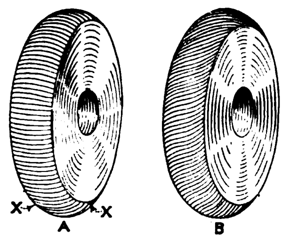

FIG. 7. PLAIN AND SPIRAL ROUND KNURLING

Surfaces formed with a radius may be knurled as shown at A and B in Fig. 7, the first being an example of convex straight and the second of spiral convex knurling. The radius of the rounding on a concave knurl, which is to produce a pattern on convex work of this kind, must be slightly greater than the radius of the piece to be knurled, in order to prevent tearing of the work at the corners marked X in the illustration. A knurl for work of this sort is produced on a simple swivel tool-holding device, Fig. 8, the work being mounted on an index center and the single-point tool being swung on a radius across the face of the knurled blank. The point D shows the position of the pivot in producing a convex knurl, and E shows the position of the pivot when making a concave knurl. Both concave and

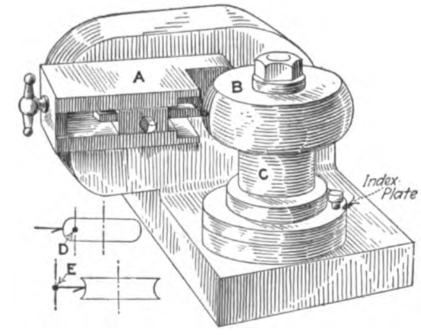

FIG. 8. ARRANGEMENT FOR CUTTING CONCAVE AND CONVEX MASTER KNURLS

convex knurls may be produced on the same device by shifting the position of the index center and of the tool with relation to the pivot pin.

Spiral convex knurling, such as shown at *B*, gives a very pleasing appearance, but requires more complicated arrangements for making the knurl. The universal miller is set up as for the straight-faced spiral knurl in Fig. 6, except that the tool is placed horizontally as at *B*. A templet is provided having a radius equal to that of the knurl, and this is followed with the cross-feed, while the longitudinal feed produces the spiral. When a knurl is required for a pattern like that in Fig. 9, in which the diameter

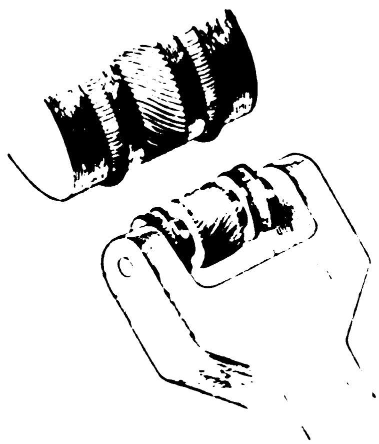

FIG. 9. HOLDER AND SPACING COLLARS FOR "BUILT-UP" KNURL

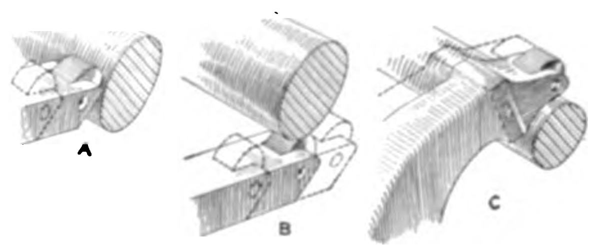

of the various knurled portions vary, it is a good scheme to make a "built-up" knurl with one roller for each portion and spacing collars between. The separate knurls are thus free to rotate at different speeds to suit the diameter of the work. Even on work of one diameter, in which three or four spots are to be knurled in this way, a built-up knurl will often prove a good investment, as it enables the pattern to be changed and a broken tooth does not cause as much loss as it would in the case of a solid knurl. There is a variety of ways to knurl in the hand screw machine and automatics. Sometimes the knurl is mounted on the cross-slide and is advanced directly in the work on the center line, as illustrated at *A*, Fig. 10, feeding in to the depth of the tooth and remaining a moment before being withdrawn. Another plan is to pass the knurl under the work, as at *B*, allowing it to rest a moment on the center line so that the tooth impressions become fully developed. Another plan makes use of the swinging arm, as at *C*, otherwise being similar in principle to *A*. Knurling

FIG. 10. GENERAL WAYS OF KNURLING ROUND STOCK ON SCREW MACHINE AND AUTOMATICS

with a box tool having roller backrests is shown at *B*. The knurl *E*, Fig. 10, is swung in toward the work by means of the eccentric *F*, and the plain rollers *G* running on each side of the knurled portion serve as backrests and balance the cut.

In connection with backresting, the location of the knurls and their number have an important effect on the strain produced in the work. The most common arrangement is illustrated at *A*, two knurls being held against one side of the work, resulting in a heavy unbalanced pressure. When one knurl is placed diametrically opposite the other on two opposite sides of the shaft, conditions are much better, although there still is a tendency for the rollers to ride up on the work in the direction of rotation. The scheme shown at *C* is the best of all, two rollers being mounted on one side of the shaft and one on the other, all tendency for rollers to ride up on the wo k being eliminated.

Ornamental knurling is an art not often practiced in the small shop. Artistic results can be obtained by knurls made as shown in Fig. 12, of which the result pictured at *A* is an example. The first step is to put in the ground lines, which consist of straight, fine-tooth knurling running across the piece, as at *B*. Punches are

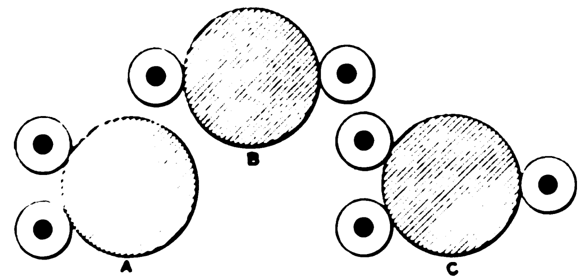

FIG. 11. GOOD, BETTER AND BEST COMBINATIONS

made carrying one unit of the figure, such as shown at *C* and *D*. The work is then held upon the arbor of an index head, as at *E*, and the pattern is stamped by means of a hardened punch sliding in a fixed guide *H*. Doing this work by hand is a delicate job, requiring a great deal of skill in giving the blow required to make the impression. A better way is to rig up a light drop that insures the same weight of blow for each repetition of the figure. The fine-ground lines at *B* are not put in simply for ornamental effect, but to serve the purpose of gearing the knurl to the work. They are quite necessary on ornamental designs of this kind, which are not positively driven, but in which the knurl depends for its rotation and registry upon its contact with the work.

Another way to repeat a design of this sort is by rolling. A hob carrying a single impression is applied to the work by gears having teeth so figured that the hob is brought into contact with the surface of the work at a different place each revolution, until the entire surface has been covered with impressions. For example, if 40 impressions are desired on a circumference, these may be obtained by using gears having 40 and 39 teeth respectively, the former connected to the blank and the latter to the hob.

In making a knurl, use tool steel having a carbon content between 90 to 110 points. Make the hole for the pin on which the knurl is to rotate small in diameter

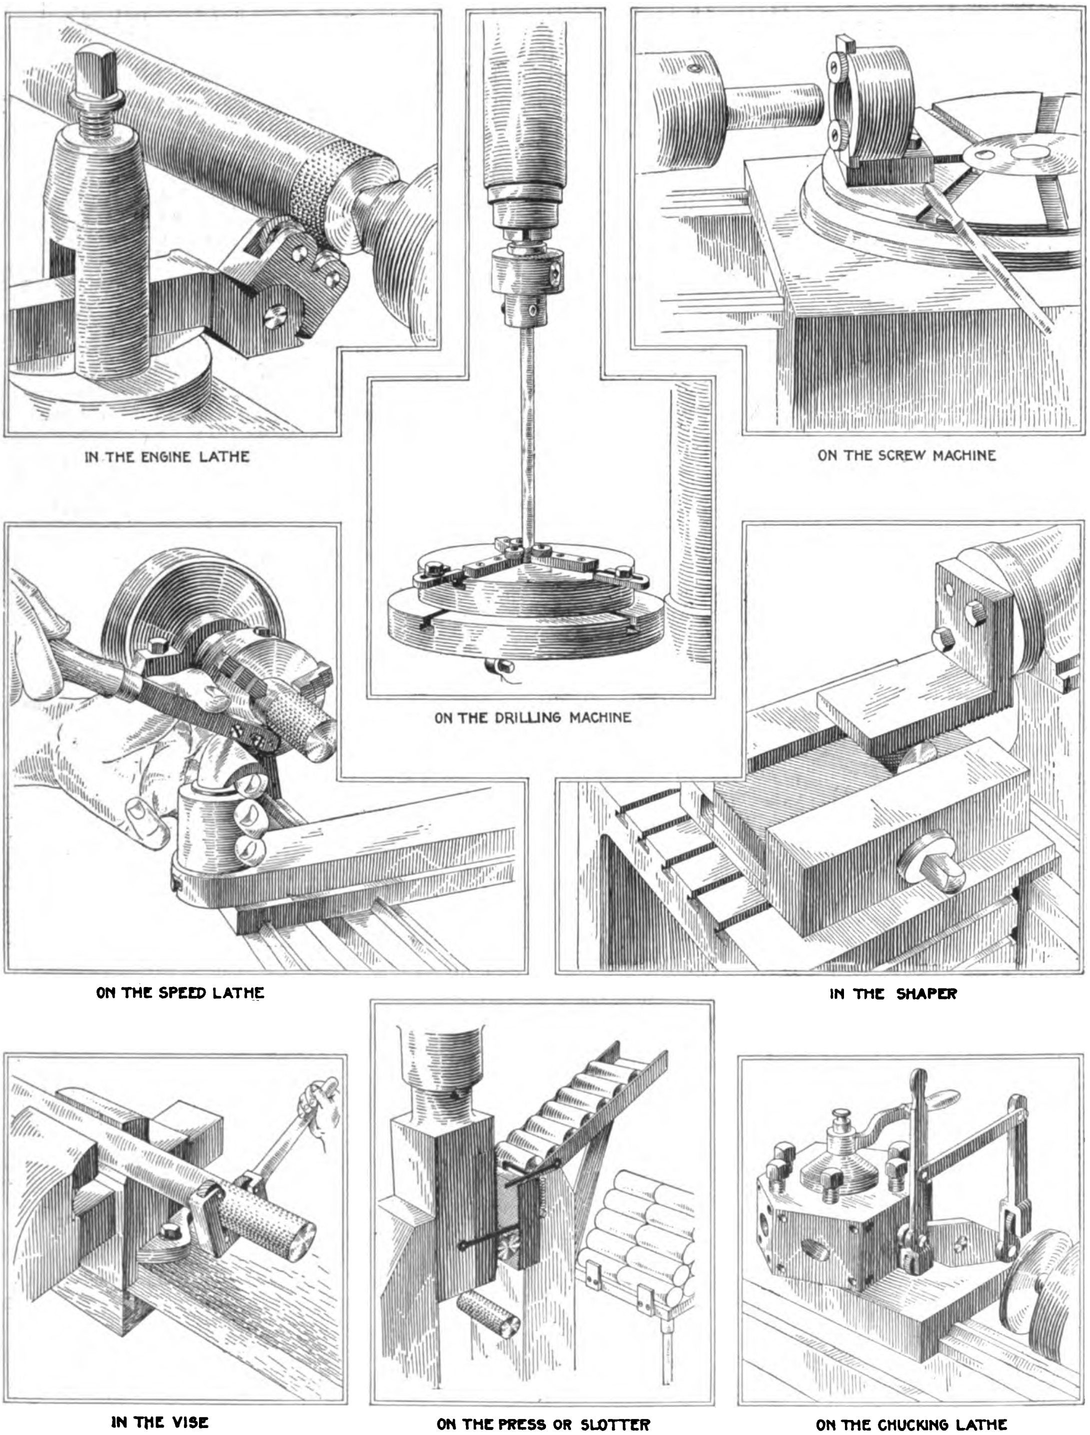

FIG. 17. KNURLING DONE ON ALL THE TOOLS IN THE SMALL SHOP

in order to reduce friction, and leave a collar on the side of the knurl for the same purpose. For a fancy knurl of complicated design it is best to use nonshrinking steel. Harden at a temperature corresponding to its carbon contents, as described on page 417, applying file cutters' paste to the knurl before heating. This is made up according to the following formula: Pulverized charred leather, 1 lb.; fine family flour, $1\frac{1}{2}$ lb.; table

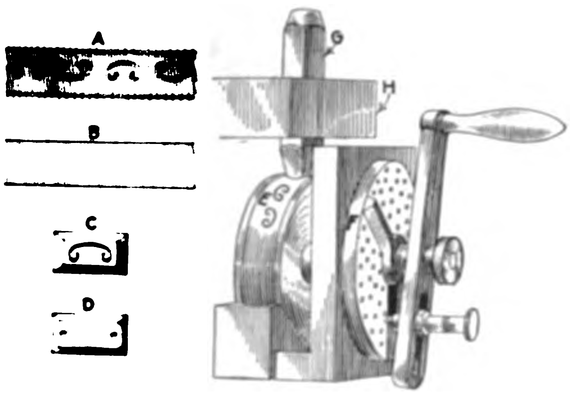

FIG. 12. ONE METHOD OF PRODUCING AN ORNAMENTAL MASTER KNURL

salt, 2 lb. The charred leather should pass through a 45-mesh screen. The ingredients of this paste are mixed dry, after which water is added slowly and it is kneaded to prevent lumps from forming. It is used at the consistency of thin molasses, is applied to the knurl with a brush and allowed to dry before the piece is heated. After heating, the knurl is quenched in water and then drawn to a color between dark yellow and yellow brown.

Some 20 years ago Edward Board, of Philadelphia, devised the triple adjustable knurl seen in Fig. 13. It combines the balance of forces described at *C*, Fig. 11, and has the good feature of being adjustable into the

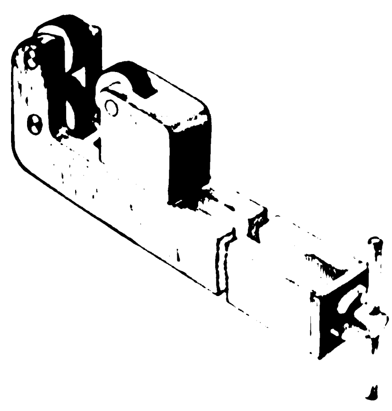

FIG. 13. ADJUSTABLE TRIPLE KNURL FOR HAND OR LATHE KNURLING

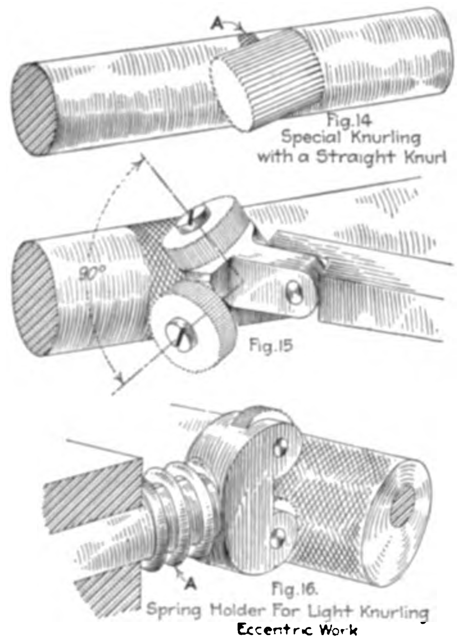
bargain. Mr. Board says that all small-shop owners are welcome to this idea, which is not patented, and which I can say from observation is a mighty good one for either hand or tool-post knurling.

One way to produce spiral knurling is shown in Fig. 14. In this case a straight knurl is inclined at an angle with the axis of the work and fed along by the tool carriage. This scheme is especially good for producing deep spiral knurling, as the teeth are cut to their full depth at the center of the knurl and there is no tendency to break off the tooth corners. This advantage is offset by having to use a comparatively slow feed, since the band produced by a single rotation of the shaft is much narrower than would be produced by the knurl held parallel with the axis, as is clearly indicated at *A*, Fig. 14.

An adaptation of this principle for double spiral knurling is given in Fig. 15. In this case we have



FIGS. 14, 15 AND 16. SPECIAL APPLICATIONS OF KNURLS

two straight knurls, both of them mounted and held at angles to the axis of the shaft and at right angles with respect to each other. The result is a diamond knurling, similar to that which would be made with a single spiral knurl held parallel to the axis. Deeper impressions of coarse pitches can be made with a knurl of this kind than with a spiral diamond knurl.

A scheme that has been used for knurling eccentrics is illustrated in Fig. 16. The tools are kept in contact with the work by means of the spring *A*, which must be sufficiently stiff to force the knurls into the work before the spring yields.

Sometimes knurled effects are produced not by knurling, but by stamping. An illustration of this is seen

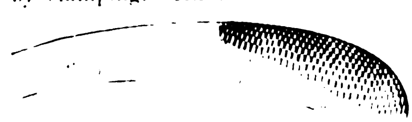


FIG. 17. KNURLED EFFECTS ARE PRODUCED BY STAMPING

in Fig. 17, which represents the roughening of one of a pair of plier handles by this simple means.

Although there is as a rule a machine best fitted for each kind of work to be done, this does not seem to hold true when it comes to knurling. The illustrations in Fig. 18 show how knurling may be accomplished in every machine usually found in the small shop and also by hand in the vise. If all work was subjected to such flexibility of handling, the small-shop man's trouble would be over!

Making Shell-Boring Cutters

Editorial Correspondence

Munition making in the United States has brought to the surface a number of things that have been concealed in the past. This work has taken on such an intensive form and production has been rushed to such a point that deficiencies are felt which would have been overlooked in the ordinary course of business. Shops have been crowded until their productive capacity has been squeezed against the sides of the buildings; and like feet squeezed into shoes too small for them, the corns and callouses make themselves unpleasantly evident.

This condition has brought about a definite idea of the value of the concentration of all the energy on one thing and has had its effect on the old policy of making versus buying small tools. A few years ago it was not uncommon to find shops buying one tool or a few tools when these were required, but rigging up to make them as soon as increased production called for larger numbers. Nowadays, under more strenuous conditions, the opposite policy has been put into effect—namely, making the one tool or the few tools and buying the quantity.

In shops with a production ranging from 1,000 to 12,000 shells per day the demand for cutters becomes enormous; and while it has been possible to double and sometimes triple the square-foot producing capacity of the machine stop by the use of specialized machines and

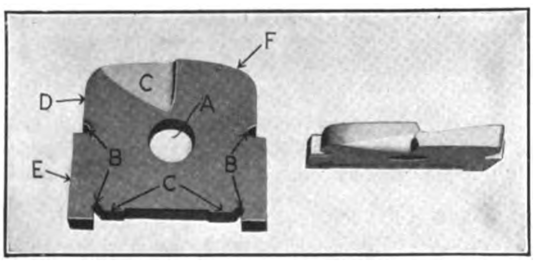

FIG. 1. BORING CUTTERS FOR 3-IN. SHRAPNEL SHELLS

attractive piece prices, it has not been possible to apply this scheme in the toolroom. If the toolroom were to be made to keep pace with the manufacturing part of the plant, it would be necessary to double or triple the floor space devoted to it; and floor space is at present worth its area in gold leaf.

One of the tools in greatest demand for shrapnel work is the step cutter used in reaming the powder pocket and disk seat. One of these cutters is illustrated in Fig. 1. It is this size that is used on 3-in. Russian shells, and the illustration shows the cutter as it appears after being milled and before hardening. It is customary to make these cutters to finished shell size and, when they wear down, use them for roughing cutters.

These cutters, as manufactured by A. Hankey & Co., Rochdale, Mass., are made from flat high-speed steel stock and require almost as many operations to finish them as do the shrapnel shells themselves. The bars are first cut into lengths, then milled on each side, after which the pin hole *A* and the clearance holes *B* are drilled. Following this operation, the edges are rough milled, this in itself being a job that requires a half-dozen separate chuckings. The next step is to mill the lips *C* in the top edge of the cutter, which is done by holding the piece on an angle block on the miller and feeding in nearly to the pin hole at the deepest part of the cut in the center of the blade. After these lips have been completed, the cutter is ready for hardening. Oil-burning muffle furnaces are employed. The fuel is

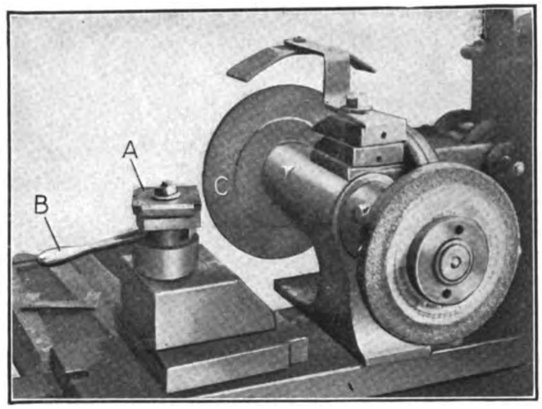

FIG. 2. CORNER-ROUNDING FIXTURE FOR SHELL CUTTERS

vaporized by steam, which has much less decarbonizing effect upon steel than air used for the same purpose.

The cutters are slowly preheated to 1,500 deg. F., after which they are placed on end vertically within the furnace and the heat is rapidly raised to 2,250 deg. At this point the high-speed steel begins to "sweat." It is then quenched in a cooling bath of Houghton's soluble quenching compound. The scale is removed by hand grinding, in order that the cutter may be tested for hardness, which is held between 85 and 90 on the scleroscope scale.

Most of these cutters are located in the boring bar by the base spots *C* and by the shoulders at each side of the spots. Some, however, are located by the pin hole *A*, and in a few cases the cutters are located by both the base spots and the pin hole, which doubles the difficulty of finishing them. There is apparently no standard prac-

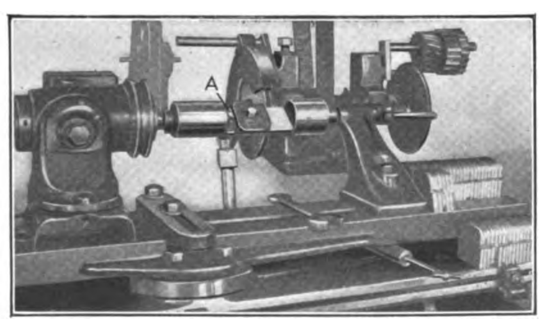

FIG. 3. GRINDING THE SIDES OF SHELL CUTTERS ON GRINDING ARBOR

tice on this point; and since work is being satisfactorily produced on cutters located by the hole only or by the spots only, it would seem as though the manufacturers who insist on locating by both of these are incurring unnecessary expense.

The cutting edges, since they are located by the base spots *C*, are the next to be ground, a number of cutters being clamped together for this operation. The shoulders on each side of the locating flats are trued up by means of a cup wheel, after which the edges *B*, *E* and *F* are ground. Then the flat sides of the cutter are surface-ground, and the lip *C* on each side is finished on a fixture similar to that provided for milling.

The fixture used in rounding the corner *F* is illustrated in Fig. 2. The cutter is held on a rotating block

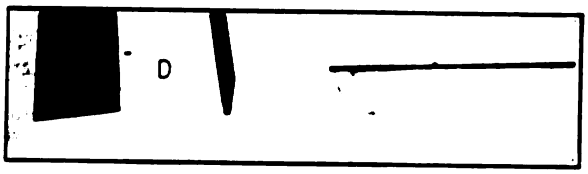

FIG. 4. TOOLS FOR CUTTING OFF COPPER DRIVE BANDS

at *A*, being clamped by a nut and washer upon a central stud. As the handle *B* is moved back and forth, the proper radius of the corner is secured through contact with the wheel *C*, a spring pressing this fixture forward until it comes to rest against a limit stop on the inside of the slide.

The method of rounding the parallel edges *E* is shown in Fig. 3. A special arbor is employed, recessed at its center to receive the cutter, which is located by a plate *A* fitting into the base recess of the cutter.

Another tool that is a development of munition making may be seen in Fig. 4. This is a high-speed steel cutting-off tool for parting copper driving bands. It is an ex-

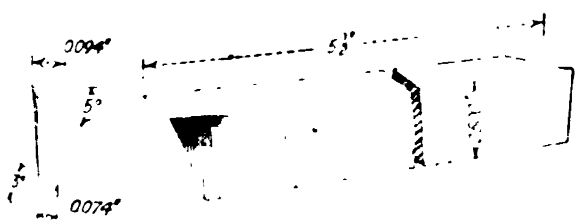

FIG. 5. DIMENSIONS OF CUTTING-OFF COPPER-BAND TOOLS

cellent example of thin high-speed steel toolwork; the dimensions of the tool are given in Fig. 5. Tools of this kind are made and hardened in lengths and cut off on an abrasive saw. It is necessary to grind at five different angles in producing such tools, and they are held within one-half thousandth of finished size on each dimension.

Cutting Gears on a Planer

By F. M. A'Hearn

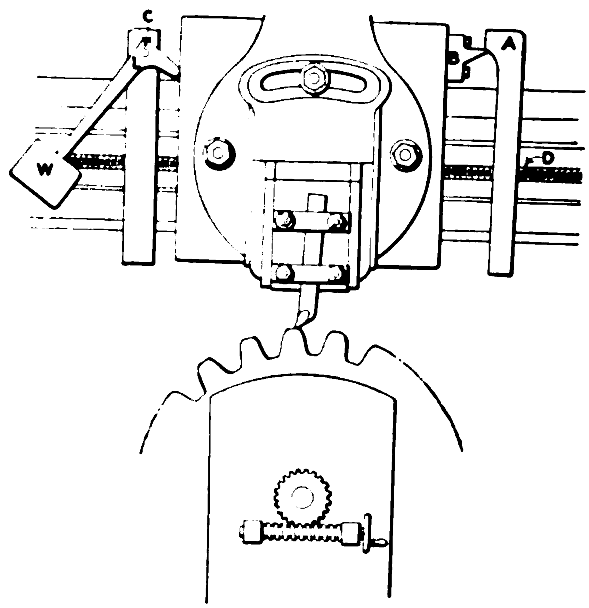
A lot of rough cast-steel gears about 3 ft. in diameter, with 18-in. faces and of coarse pitch, requiring the teeth to be machined, would not appeal to the average shopman as an attractive planer job. A plant equipped for building heavy machinery was confronted with a problem of this kind; and to avoid the delay of letting the work out, it was decided to finish the teeth on a planer.

A hardened block *A*, shaped to the required contour of the tooth, was bolted to the cross-rail. A follower *B*, having a narrow bearing against the side of *A*, was secured to the head. The fulcrum *C*, on the opposite side, supported a bell-crank lever *L* with a weight *W*, as shown. The crossfeed screw *D* was released at the ends to allow it to travel with the head.

With the work mounted on a rigid pair of planer centers, the tool was located at the top of the tooth. As the crossfeed screw was inoperative, slight side adjustments were made by moving the tool before drawing the nuts tight.

When the cut was started and the vertical feed thrown in, the weighted lever *L* held the follower *B* against the former *A* as the tool traveled down the cut, and the required contour was secured.

After the teeth were finished on one side, the fixtures were reversed and the other side completed in the same



AN IMPROVISED METHOD OF CUTTING HEAVY GEARS ON A PLANER

way. Sufficient clearance was cast at the bottom of the teeth to require no finish.

Slight errors were of course present in the finished work, but the gears were entirely satisfactory or, to quote one of the old-time contributors to the *American Machinist*, "They were sufficiently accurate for practical use."

Machinery Club of Chicago

The Machinery Club of Chicago has been formed as part of a get-together movement of machinery builders and dealers. The first meeting was held at Hotel Sherman on Apr. 17, 1916, and 130 enrolled as charter members. Only residents of Chicago directly connected with machinery or machinery supplies are eligible, but anyone outside of Chicago connected with machinery or machinery supplies will be welcomed as a guest. C. W. Blakeslee, Chicago manager of Abrasive Materials Co., acted as chairman, and Mr. Noble, of the E. L. Essley Co., as secretary.

Club luncheons are to be held every Monday at 12:15 p.m. and stated meetings once a month will be held in the evenings.

Jones & Lamson Fixtures for Textile-Machine Details

By Robert Mawson

SYNOPSIS—The illustrations show the construction and use of special tools for machining four textile machine parts. These tools are all for use on Jones & Lamson flat turret lathes. The fixtures are of rigid construction and employ sliding wedges, setscrews and jaws for locating and holding the work.

On these jig and fixture data pages are shown turret lathe fixtures for machining four textile machine parts. These parts are a web take-up bracket, a transfer cup, a transfer ring and a double-stitch cam. The special features were designed for, and are used on, Jones & Lamson flat turret lathes. The shop where they were designed and built and are used is that of the Hemphill Manufacturing Co., Pawtucket, R. I.

A consideration of the illustrations will show that the fixtures are simple in design and rigid in construction. In connection with each of the four details on page 853 are given the production time for each piece.

The methods of holding the pieces in the fixtures are worthy of study. The web take-up bracket, Fig. 1, page 853, is held in its fixture by two sliding wedges forced against the sides of the casting by means of square-headed set screws.

This is clearly shown in Fig. 2, which also gives a good idea of the substantial nature of this fixture. The opening in the piece to be machined slips over the two projecting jaws and seats on the base of the fixture. Then the wedges are easily and quickly slid into place and locked.

In the next piece shown—the transfer, cup, Fig. 3—the work is held in the special chuck shown in Fig. 4. The ear projects through the ring of the chuck and rests on the adjustable screw shown at *A*. The three radial setscrews hold the cup in place in the chuck.

The transfer ring, Fig. 5, is held in a special chuck shown in Fig. 6. This grips the ring by the large diameter and holds it laterally as well as from turning.

The double stitch cam, Fig. 7, is held in a very similar manner by the chuck shown in Fig. 8. This, however, locates the piece by its face against the face of the chuck. Two of the jaws bear against the smaller diameter and one against the outer cam face. The jaws are proportioned to center the work with the hole.

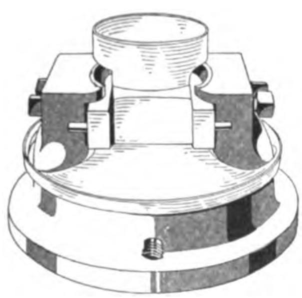

FIG. 2

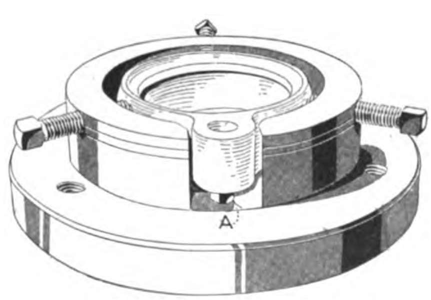

FIG. 4

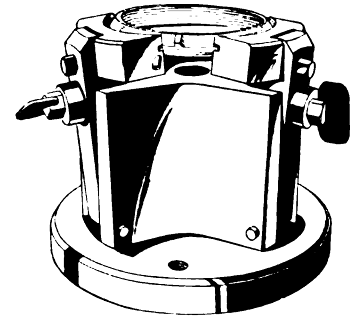

FIG. 6

FIGS. 2, 4 AND 6. J. & L. FIXTURES FOR MAKING TEXTILE MACHINE DETAILS, WITH PARTS SHOWN IN POSITION

FIGS. 2 AND 2-A

Operation—Machining the web take-up bracket, Fig. 1. The casting is placed on the fixture, and the two sliding wedges A are forced against the casting by the setscrews on the sides.

Surfaces Machined—Inside bored, edge faced and two surfaces turned.

FIGS. 4 AND 4-A

Operation—Machining transfer cup, Fig. 3. The casting is placed on pins and an adjustable screw A. The three setscrews on the sides are tightened against the part, holding it securely.

Surfaces Machined—Hole bored and inside contour turned and faced.

FIGS. 6 AND 6-A

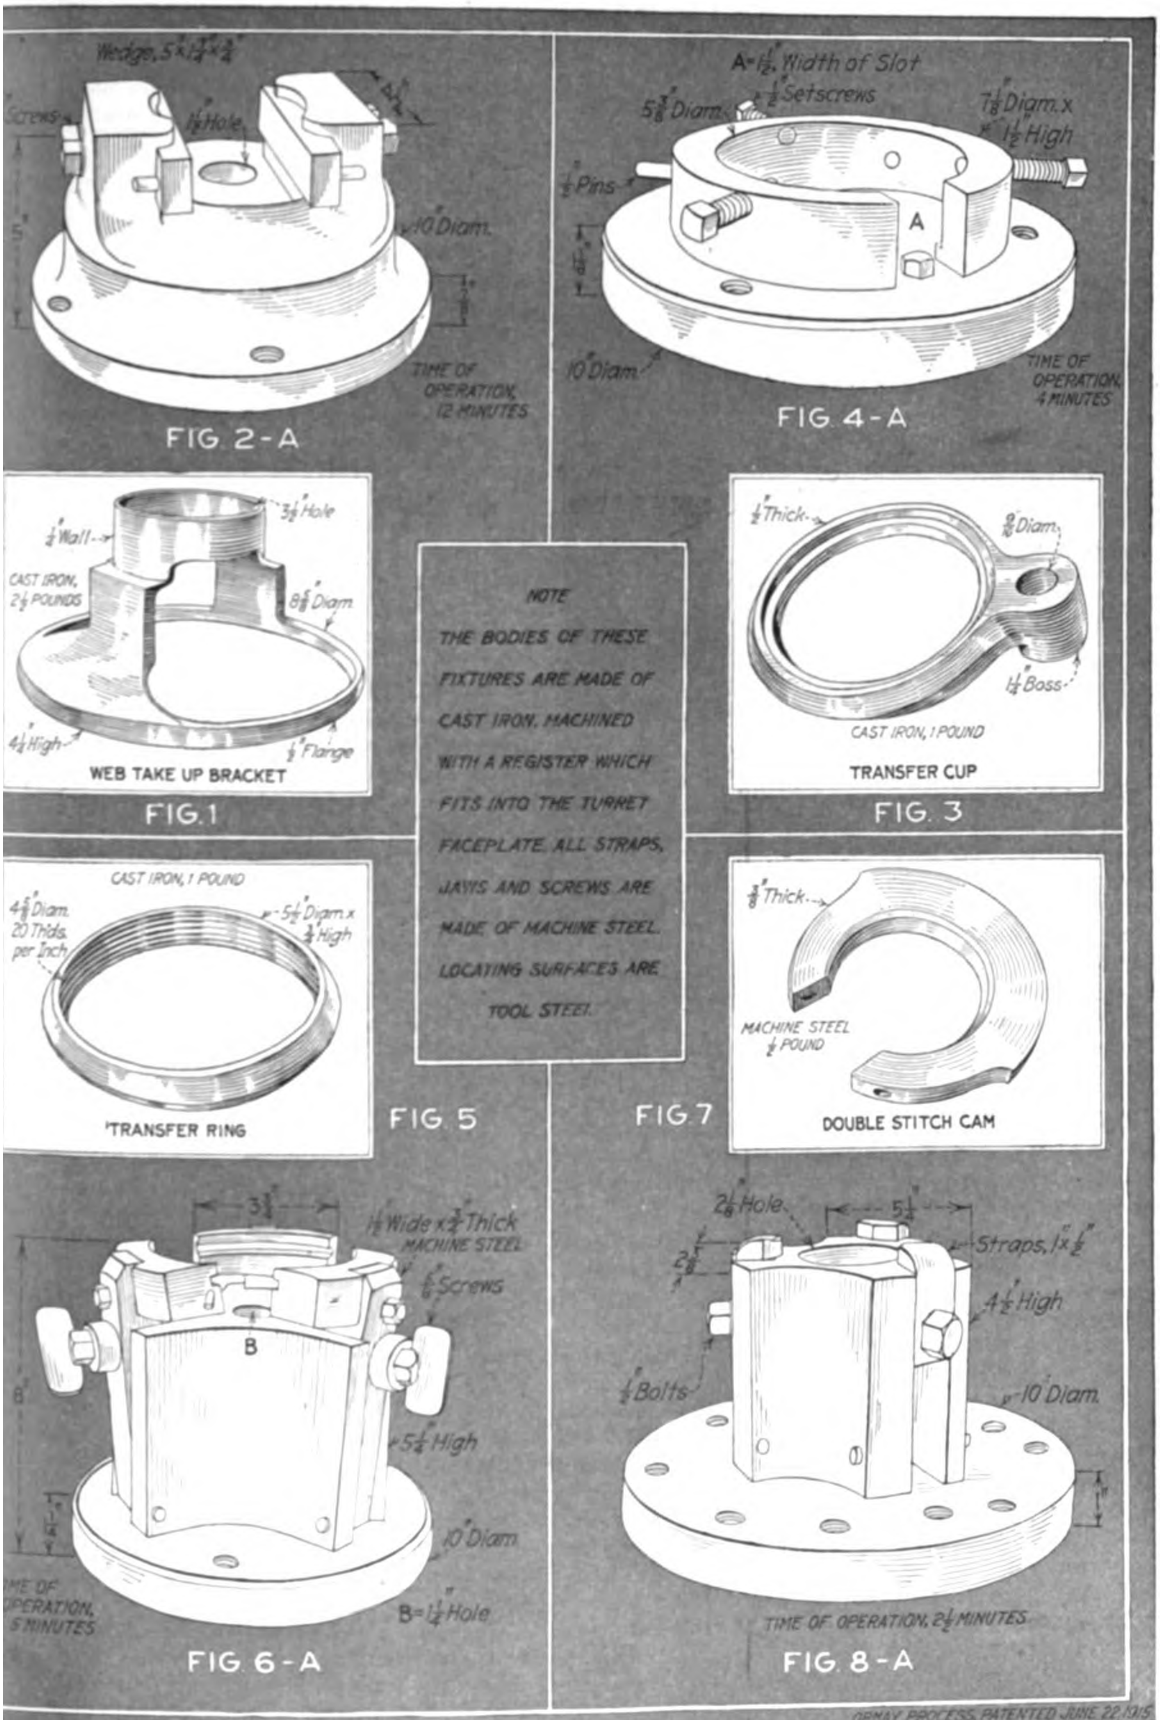
Operation—Threading transfer ring, Fig. 5. The casting is placed in the recess of the three jaws, and the screws, being tightened, force the jaws against the piece, holding it rigidly.

Surfaces Machined—Hole bored and $4\frac{5}{8}$-in. by 20 thread machined.

FIGS. 8 AND 8-A

Operation—Machining double sole cam, Fig. 7. The piece is placed on the outer surface of the fixture, and the three screws, forcing down jaws on the sole cam, hold it firmly.

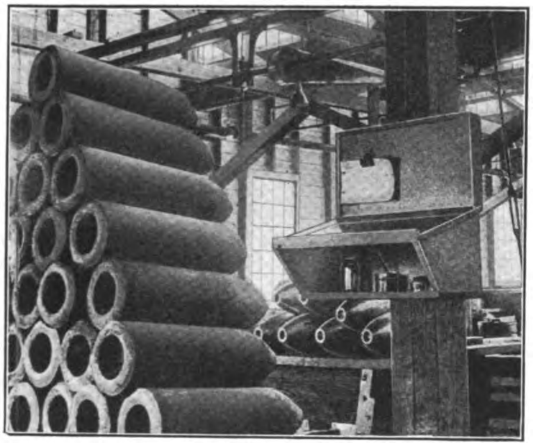
Surfaces Machined—Hole bored and outside faced. The piece is then reversed and the opposite side faced.



DETAILS OF J. & L. FIXTURES USED IN MACHINING TEXTILE-MACHINE PARTS

Convenient Desk for a Foreman

The accompanying illustration shows a foreman's desk that is most convenient. It might also be classed as portable, owing to the ease with which it can be moved from one point to another or set up on any post or wall. This desk is approximately 2 ft. long and perhaps 15 in. wide on the inclined surface, to afford ample room for writing.



CONVENIENT PORTABLE DESK

The back permits notices to be posted conspicuously or time and job slips to be hung up, as shown. In this particular case the work was the making of shells, and the marking part shown on the under shelf was for identification and also for marking the high spots when a shell was excessively eccentric.

This form of portable or temporary desk can be used to advantage where room is limited and where a change in the sequence of operations may make it desirable to transfer the desk to a new location at short notice.

Finding Surface Speeds for Machinery

By Chester E. Josselyn

Noticing a foreman obtaining a surface speed with watch in one hand and recording instrument in the other gave rise to the thought why it should be necessary to repeat this operation for each piece of work presented.

Of course, it is conceded that there are a right and a wrong speed for all kinds of tools and for the different materials worked by the various machines; also that by the selection of the proper speed for the work to be done the life and efficiency of both tool and machine are greatly increased.

Both the engineering department and the shop foreman are fully aware of these facts and can in most cases dictate very readily the necessary travel the work should have; but when it is given in this way, as so many feet per minute, many workmen are at a loss to know how to go about to find the nearest available speed, although the calculation requires but a knowledge of elementary arithmetic.

It seems that with a little effort a constant could be stamped on each step of a cone pulley, and this, multiplied by the diameter of the work to be turned or bored, would give its surface speed directly, reducing the mathematical operation to a minimum, except where a tabulation was made for each individual machine. Thus, mark each cone-pulley step with a constant equal to

$$\frac{\textit{Surface speed in feet}}{\textit{Diameter of step}}$$

Then the constant multiplied by the diameter of work would equal the surface speed of the work.

To illustrate: We find by using a surface-speed instrument or by calculation that the largest step, 10 in., has a surface speed of 175 ft. per min. Dividing this by the diameter, 10, equals 17.5, which should be stamped on the face of the pulley. A piece of work of known diameter, say 5 in., is to be turned; what will be the surface speed in feet of work with the belt on the 10-in. step?

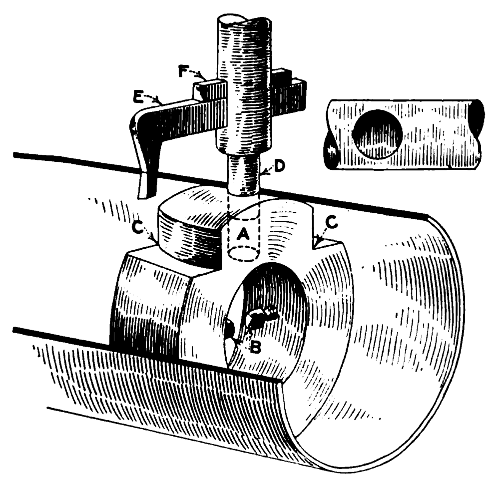
$$17.5 \times 5 = 87.5 \textit{ ft.}$$

There is no doubt that general satisfaction would be created in most machine shops if these constants were indicated.

Boring Tool for Copper Pipe

By Elmer C. Braden

Some time ago I had to cut 4-in. holes in a 6-in. copper pipe that was 1/8 in. thick. The holes were placed spirally around the pipe, about 12 in. apart. Their locations were first laid out on the pipe and a 3/4-in. hole drilled in the center. An inner ring with the hole *A*, which is also 3/4 in. in diameter, was placed on the inside of the pipe with the hole in line with the machined 3/4-in. hole. The ring was held in place with the set-



BORING TOOL FOR COPPER PIPE

screws *B*. The spaces *C* were cut away to prevent the tool from striking the ring after cutting through the pipe.

The projection *D* was put through the 3/4-in. holes in the pipe and ring. The bar was fitted with a tool *E*, held by a key *F*. The operations were performed on a common drilling machine, and the feed was by hand. The ring was moved from one position to another, and a true, clean hole was obtained.

Welded Tips on Cutting Tools

By C. B. Auel*

SYNOPSIS—A study of the welding of high-speed steel tips to machine-steel shanks in a large plant. Four methods of welding are described. The increased price of high-speed steel has made this course economical in instances where it would not ordinarily be good practice.

Under ordinary commercial conditions the welding of high-speed steel tips to machine-steel shanks is not to be recommended as an economical proposition. This may seem a rather startling statement to make, and it should be modified to the extent of saying that it does not apply to special tools involving a considerable weight of material; but it does apply to the great majority of lathe, boring-mill, planer tools and the like, such as are used daily in the average machine shop. However, under conditions as abnormal as they are at present, with the prices of high-speed steels reaching undreamed of figures and these materials, in fact, becoming increasingly difficult to obtain at any prices, the proposition is not only an economical but a necessary one.

The welding of high-speed steel to machine steel may be effected in several ways—(1) by the electric arc, (2) by the electric incandescent or resistance process, (3) by the oxyacetylene flame or (4) by the gas furnace. Which of these is the cheapest will depend upon the facilities already at hand, including not only the equipment, but the operators as well; for it must be said that this is a class of work in which skilled help is an essential, if uniformity in product is to be secured.

Generally speaking, the most uniform results are to be obtained through the medium of the electric incandescent or resistance process, it being not only the quickest, but the most nearly foolproof of the several processes mentioned and therefore requiring the least-skilled grade of operator. This process is one of butt-welding. The two pieces of steel—one high-speed and the other machine steel—are securely clamped in the jaws of a suitable welding machine, with their adjacent ends either somewhat rounded or even squared off and butting hard against each other. Fusion takes place upon current being passed through the abutting ends, and the weld is made. The time required, including setting the pieces in position in the jaws, welding and subsequently removing the pieces, is very little, possibly 2 or 3 min., depending in the main upon the size (cross-section) of the materials.

The current required will likewise depend largely upon the cross-section of the materials, though to some extent upon their composition, etc., reaching as high as 60 kw. for a 2-in. diameter section or the equivalent. In welding by this process alternating current is used, and the periodicity may range from 60 to 25 cycles, though the former is to be preferred. The machine-steel shank may be of any length desired, while the high-speed steel nose or tip may be as short as 1 in., though a length of 1½ in. is rather better, because the weld is usually exceedingly hard and, as the nose or tip generally requires some shaping after welding, the extra length will keep this hard portion beyond the area to be thus worked upon. Another reason for this increased length, though not so important, is that, when the tool is in actual use, the chip has a tendency to extend beyond the high-speed steel nose or tip to the machine-steel shank and wear the latter away, so that it is advisable to make the nose or tip sufficiently long to take such wear.

To prepare the pieces of steel for welding, it is only necessary, as already intimated, to have them of the same cross-section, to cut them off to suitable length and to square off or round their abutting ends. Sometimes the high-speed steel nose or tip may be forged to the desired shape before welding. Immediately upon being welded the tool is allowed to cool in lime, after which the fin at the weld may be ground off and the tool otherwise finished in the usual manner. The disadvantages of this process are that a special equipment is involved—one not likely to be found in the average machine shop—and the amount of high-speed steel required is rather greater than in any of the other processes.

The electric-arc process similarly requires a special equipment, but one that is more likely to be found in the average machine shop, it being exactly the same as the equipment required for the welding or repair of steel castings. It has been described very completely in previous issues of the *American Machinist*.

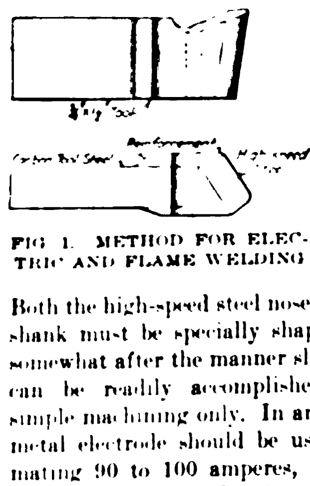


FIG. 1. METHOD FOR ELECTRIC AND FLAME WELDING

Both the high-speed steel nose or tip and the machine-steel shank must be specially shaped preparatory to welding, somewhat after the manner shown in Fig. 1. This shaping can be readily accomplished; the operations involve simple machining only. In arc-welding, a $\frac{5}{32}$-in. diameter metal electrode should be used with a current approximating 90 to 100 amperes, and the work, furthermore, must not be hurried. A good operator should be able to make between 25 and 30 welds for tools of 1½x2-in. cross-section in a day of 9½ working hours.

Considerable difference of opinion exists among individual operators as to the material for use in the metal electrode, but all are agreed that it must be a strictly high-grade material, neither hot- nor cold-rolled wire being at all suitable. Excellent results have been obtained with electrodes of the following compositions obtainable in the open market, the first giving perhaps the best results:

No.	Carbon	Manganese	Phosphorus	Sulphur	Silicon
1	0.04	0.002	0.034	0.002	trace
2	0.05	0.140	0.007	0.025	trace
3	0.096	0.122	0.005	0.064	0.056

Regarding the material for the shank of the tool, commercial hot- or cold-rolled steel may be used; but these steels are liable to bend under the heavy stresses encountered when used as tools in actual cutting service, or they may even crack through their smallest cross-section. The bending may to some extent be prevented

*Director of standards, processes and materials, Westinghouse Electric and Manufacturing Co.

by suitably supporting the nose or tip of the tool from underneath, while the tendency to crack may be almost wholly overcome by reinforcing the tool by the addition of welding material on both sides of the weld.

The same precaution should be observed that was pointed out under the process of electric incandescent or resistance welding, in regard to making the high-speed steel nose or tip about 1½ in. in length. Instead of employing either hot- or cold-rolled steel for the shank of the tool it is by far the best to use a tool steel, even though the cost be increased. Experience has shown that

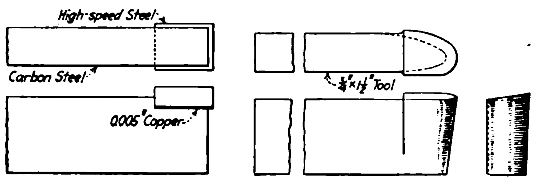

FIG. 2. METHOD FOR WELDING IN FURNACE

a tool steel of the following composition meets the requirements admirably: Carbon, 0.90 to 1.05; manganese, 0.15 to 0.30; silicon, 0.10 to 0.25; phosphorus, 0.025; sulphur, 0.025. The costs of hot-rolled, cold-rolled and tool steel will vary approximately as 1 to 2 to 4. As may be presumed, the grade of help required for electric-arc welding must of necessity be higher than that for electric incandescent or resistance welding.

The Oxyacetylene Process

In the oxyacetylene process of welding, the equipment is undoubtedly the cheapest in first cost of any of the several methods thus far mentioned, while the grade of help required will be on a par with the grade for electric-arc welding. The cost of the oxygen and the acetylene as well as of the actual labor will, however, make the cost of the finished tool run considerably higher than with either of the electric processes, even though preheating be used to reduce the consumption of gases. The pieces of steel require to be specially shaped preparatory to welding, and this may be done in the same way as shown in Fig. 1, though other shapes may perhaps be found to give equally good results.

The same remarks apply regarding the advantages of hot-rolled, cold-rolled and tool steel for the shank, as in the other processes, and the same precautions should likewise be used in reinforcing the weld for added strength and in the length of the high-speed steel nose or tip. Rather curiously the materials that give the best results for electrodes in the electric-arc process do not give similar results in the oxyacetylene process, as the best welds have been obtained with the purest grade of iron wire. This fact, though, may to some extent be due to the operator. The time required for making a weld by this process for a tool 1½x2 in. in cross-section and shaped as shown in Fig. 1 will vary from 30 to 60 min., depending upon the operator, the size of torch and whether or not preheating is resorted to.

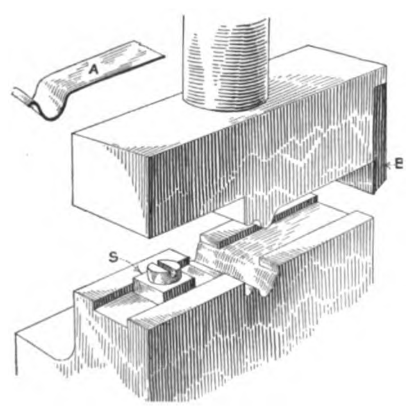
In gas-furnace welding, the high-speed steel nose or tip is laid, as seen in Fig. 2, in position on the machine-steel shank, being separated from it by a strip of copper 0.005 in. in width, the whole being then tied together by iron wire to hold it in position. Care is required in heating, as the high-speed steel nose or tip melts at a rather lower temperature than does the machine-steel shank. When the highest temperature possible short of actual melting has been reached, the tool is quickly removed from the furnace and squeezed between the jaws of a vise that has been set at right angles to its normal position for this purpose, or the tool may be placed under a drop or hammer and a single blow delivered to drive the component parts together. While this process is by far the cheapest of any of those described, the results obtained are not always uniform, both good and poor tools being produced from apparently the same treatment. The difficulty seems to lie in an air pocket sometimes forming within the area of the weld, which of course precludes a perfect union and causes failure through inability to carry the heat from the nose or tip when in use, which results in cracking.

Press Tools for Making a Brass Cable Clip

By H. King

Many modern guns are fired electrically, and this, of necessity, means that cables are used to carry the high-tension spark. The cables are fastened to the gun carriage by means of clips such as *A* in the illustration. This clip was made from a 16-gage brass strip, ½ in. wide, with the tools shown, which were used on a hand press and require little explanation.

The bottom tool had a groove, slightly wider than the strip to be used, cut along its length to guide the strip. Both tools were shaped to the contour desired. The top



THE DIES FOR A CABLE CLIP

tool was fitted with a blade *B*, which sheared the stock just before the completion of the stroke.

In use, the stock was passed along the guide groove of the bottom tool until it struck stop *S*, when the press, coming into action, formed and sheared the clip. The shearing blade of this class of tool should not be too long because if shearing takes place too soon, the sheared piece may jump the guide. The blade was made from tool steel, but the remainder of the tool was made of mild steel casehardened. While this choice of materials is somewhat unusual, the success of the tool at the shearing face justified the choice of material both from the standpoint of economy and durability.

Principles and Practice of Dynamic Balance*

By N. W. Akimoff†

SYNOPSIS—Dynamic balance is a part of the mechanics of engineering. The problem is capable of a definite solution if proposed in a rational manner and treated along rational lines. The author separates the problem into two parts—static and dynamic balance—and explains dynamic unbalance by the centrifugal couple. He describes his machine for creating a centrifugal couple at will, which may be adjusted by trial exactly to counteract the one that may be present in the body to be tested and permits definitely establishing the plane, sign and exact numerical value of the centrifugal couple of the body. Applications of these principles to the actual practice of balancing, together with explanation of working methods, are given in the article.

In this paper is described a machine that I devised to correct the condition of dynamic unbalance. The description is preceded by an explanation of the phenomenon of dynamic unbalance, made as elementary as possible by carefully excluding all references to products of inertia, momental ellipsoids, free and forced oscillations, etc. The subject of dynamic balance is not an involved one, and I feel it is time for it to be placed on a purely rational basis.

The balancing of reciprocating parts is purely a matter of calculations and of design; but the balancing of rotating parts, aside from the design, is a matter of trial and adjustment, because of its accidental nature.

In a theoretically perfect rotating body, symmetrical and made of homogeneous material, there cannot be any question of running balance—such a condition would be understood as a matter of course. But we know that in practice nearly all bodies rotating at high speeds show a certain amount of unbalance. The immediate consequences of this unbalance are vibrations in automobiles and turbines; defective commutation in electrical machinery; undue wear and strain on bearings; defective products in the cases of grinding disks for steel balls, woodworking machinery, etc.

As is well known to all, an unbalanced condition of a rotating body may be due to two distinct causes—lack of static balance and lack of dynamic balance.

By static balance is understood the condition when the center of mass of the body lies somewhere on the axis of rotation. Such a condition is easily obtained on one of the static balancing machines of the knife-edge or of the roller type. In order to place the body into static balance, it is sufficient to drill one hole or to add one weight, although either of these might be split up into one or more components whenever desirable.

Now, by dynamic balance is understood the condition when there is no so-called *centrifugal couple* in any axial plane. In a statically balanced body, Fig. 1, a centrifugal couple can only be due to *two* masses m and n on opposite sides of the shaft and located at a certain distance c axially from each other. Such masses may be, for instance, the centers of gravity of corresponding congested regions. At any rate, in view of the static balance (1) such masses must be in some axial plane, and (2) the products of each mass and its respective distance from the axis of rotation must be equal.

Such a couple is in general numerically equal to a certain coefficient multiplied by radius times weight times axial distance—that is, equal to $k\ m\ r\ c$, where k involves the speed as well as other numerical constants. Now we shall choose the unit of speed in such a manner that k can be made equal to unity, so that the centrifugal couple is equal to $m\ r\ c$ or $n\ R\ c$ (since $mr = nR$).

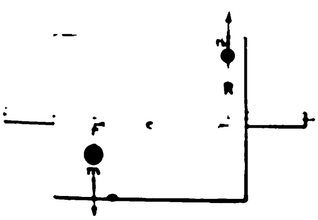


FIG. 1. CENTRIFUGAL COUPLE IN STATICALLY BALANCED BODY

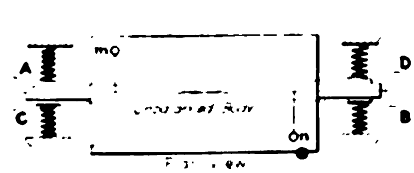

FIG. 2. FLOATING-BEARING PRINCIPLE

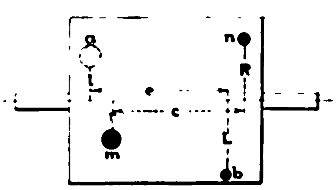

FIG. 3. COUPLE COUNTERACTING CENTRIFUGAL COUPLE

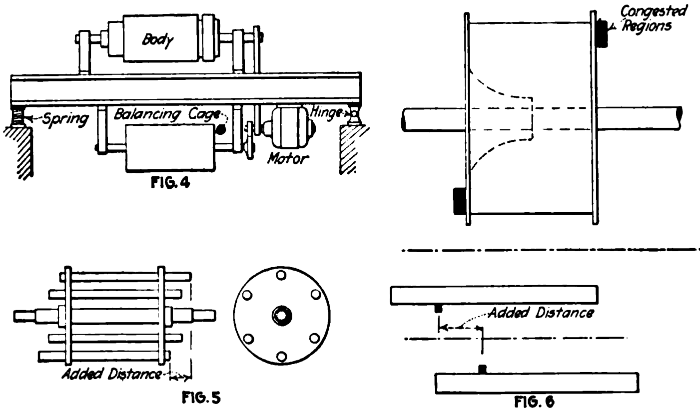
Since the effect of a couple can only be counteracted by that of another couple, it will be seen that any effort to balance such a body as in Fig. 1 by adding *one* weight or drilling *one* hole cannot fail to make matters worse. Such a method not only does not take care of the centrifugal couple, but also distorts the static balance.

It seems to be a "natural feeling" that the way to correct unbalance is to drill a hole at the "high spot"—the point where the marking tool touches the body. Indeed, it appears that various devices have been designed and are now on the market precisely for marking such "high spots," after which judicious removal of metal is supposed to secure the desired condition of balance. These devices are based upon the so-called floating-bearing principle, Fig. 2—that is, are provided with bearings yielding in the horizontal plane to emphasize the running of the body out of true. Of course, all such devices can only serve to indicate that the body is out of balance; they can give neither the true axial plane of the disturbing centrifugal couple nor the numerical value of it. Also, drilling in any one place, as has just been seen, cannot secure dynamic balance, but can only distort the static balance.

*Presented at the spring meeting, New Orleans, La., April, 1916, of the American Society of Mechanical Engineers.
†Engineer, Dynamic Balancing Machine Co.

It appears likewise that an attempt has been made to balance round disks, wheels, pulleys, etc., by pivoting them on one point and by marking the "high side." It is extremely difficult to ascertain just what is the underlying idea of such apparatus, as rotation of bodies on a fixed axis and rotation about a fixed point are two entirely separate chapters of dynamics, the latter much more difficult than the former; and the deductions of one apply in no way to the other. The same remark applies to the method consisting of rotating a body suspended on a flexible shaft (wire rope) and observing the high spots in this manner. All such attempts to ascertain the dynamic unbalance are perfectly irrational.



FIGS. 4 TO 6. PRINCIPLES AND CONSTRUCTION OF DYNAMIC BALANCING MACHINE AND SETTING OF BARS FOR AN UNBALANCED FAN

Fig. 4—Principle of dynamic balancing machine. Fig. 5—Construction of squirrel cage. Fig. 6—Dynamic unbalance in special fan

What it is absolutely necessary to know in a statically balanced body is: (a) The exact location of the axial plane of the disturbing centrifugal couple; (b) the exact numerical value of the disturbing couple; (c) the sign of the couple—that is, the direction of the vector representing the couple. Indeed, with the axial plane of the disturbing couple known, attention can be limited to that plane; and what is done on one side of the shaft will be repeated on the other side so as to preserve the static balance. Furthermore, with the numerical value of the couple *m r c*, Fig. 3, known, all that has to be done to secure dynamic balance is to introduce an opposing couple *a l e* of the same magnitude. Of course, this counteracting couple can be introduced in a variety of ways, small holes drilled on a large radius and far apart axially being equivalent to larger holes located on smaller radii and nearer to each other axially.

It will be seen from the foregoing that a machine to deserve the name of dynamic balancing machine absolutely must indicate the plane of unbalance as well as the numerical value and sign of the unbalancing couple. I claim to have produced such a machine, of which the following is a brief description:

A rigid horizontal beam, such as a lathe bed, Fig. 4, is hinged at one end and supported by a spring at the other. The body to be tested, already in perfect static balance, is rotatably supported on the beam. If dynamically unbalanced, the body will, when rotated, cause the beam to vibrate in a vertical plane, with a period of oscillation equal to the period of rotation of the body. In other words, if the speed of the unbalanced body is, say, 315 r.p.m., the beam will vibrate at the rate of 315 complete oscillations per minute, quite regardless of the characteristics of the spring (except possibly at the very beginning of motion). Now imagine a second body, exactly similar in every respect to the first, also in perfect static balance, but dynamically unbalanced to precisely the same extent as the first body, temporarily associated with the same beam, say suspended under it. If these two bodies are oppositely located as to balance and run precisely at the same speed (synchronously), then the unbalancing or disturbing couples will cancel out and the beam will have no tendency to vibrate, no matter how badly unbalanced individually are the two bodies. This is the fundamental principle of the machine—to determine unbalance by determining the unbalance necessary to neutralize its effect. In the actual machine, instead of the second body being an exact image of the original unbalanced body it is a so-called squirrel cage, and this is rotated in unison with the article to be tested. The cage, Fig. 5, consists of two or more circular disks, carrying an even number of rods (usually six or eight) arranged slidably in the disks. The rods are accurately made, and their common weight is known; therefore, any displacement of one of the rods with respect to the one exactly opposite will not affect the static balance, originally perfect, of the cage, but will introduce a certain centrifugal couple, according to the relative displacement or *added distance*.

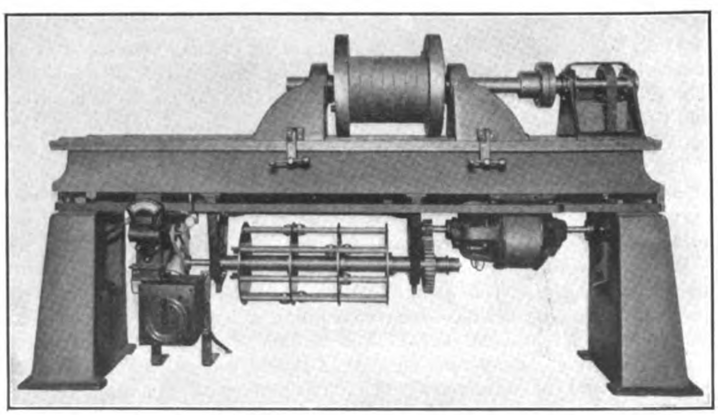


FIG. 7. AKIMOFF'S DYNAMIC BALANCING MACHINE

For instance, suppose that the unbalanced body is a special fan, Fig. 6, and that the unbalance is due to two excess weights, grossly exaggerated in the figure. This

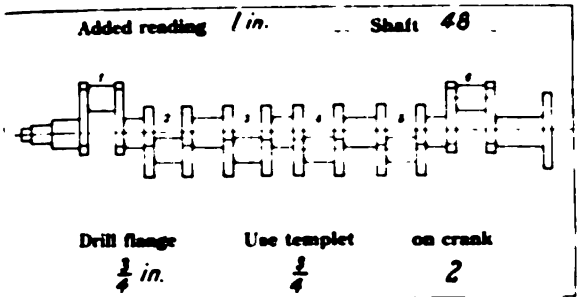

FIG. 8. DIRECTIONS FOR BALANCING SHAFT

will result in a centrifugal couple; and to counteract it, the cage will have to be put into a state of unbalance, as shown by the relative displacement of the rods and as measured by the added distance.

Thus the cage has means for indicating the exact amount of unbalance which has been put into it in order to reproduce with the opposite sign the exact unbalance of the article being tested. For instance, the displacement or added distance of 1¾ in. may represent (for a certain speed) a couple of, say, 120 oz.-in. The plane of unbalance is easily established by the location of the two rods, the moving of which into a new position stops the vibrations; and the value of the couple is immediately given by the added distance.

It should be clearly understood that the centrifugal couple due to the body acts upon the beam in a simple harmonic manner—that is, according to the law of sines—but so does the effect of the balancing cage. In other words, when the axial plane of unbalance is vertical, the effect of unbalance on the hinged beam is the greatest, as also is the effect of the correcting element, the cage.

When the plane of unbalance is horizontal, that of the correcting element is likewise horizontal, since the cage and the body rotate in unison and neither is in any manner felt by the beam, which does not respond visibly to any but vertical efforts or the vertical components of other couples.

So far as the spring, Fig. 4, is concerned, its object is to intensify the amplitude of the vibrations, although an unbalanced body will always cause the whole bed to vibrate with a frequency corresponding to the speed of the body (on this principle is based the well-known vibrating tachometer).

However, there is an additional advantage in the use of the spring, as it is always possible to select the characteristics of this so that, under its load, its free period of oscillation will correspond exactly to the rate at which it is desired to run the test. Such a synchronism has a large magnifying effect, so that even a slight unbalance results in a considerable amplitude of oscillation. The natural period of oscillation of the spring is calculated from

$$T = 2\pi \sqrt{M U_d}$$

where

T = Period in sec. of one complete (double) oscillation;

M = Mass by which the spring is actually loaded;

U_d = Unit deflection, feet per pound of load;

π = 3.1416.

The details of construction of the cage would not be of any material interest in the present discussion, but the main feature is that the rods can be adjusted axially while the cage is in rotation, the speed of the cage never being higher than 400 r.p.m. or so.

With regard to the proper speed at which to balance a body, I submit the following considerations: Unless the

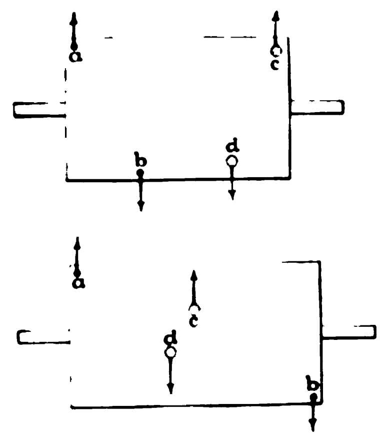

FIG. 10. SPECIAL CASES OF CORRECTING COUPLE

body itself is elastic or is mounted on a flimsy shaft, the body balanced at any speed will run true at any other speed. If the shaft is not strong enough, no balancing machine can make it stronger. If the windings of a rotor seek to find their places under a certain speed and temperature, they should be allowed to do so, after which balancing can be done. In the high-spot method, in which azimuth (commonly known as lag or lead) depends upon the speed itself, it is of course of considerable importance to watch the speed; but in the rational method here proposed the best speed is determined only by the characteristics of the spring, Fig. 4.

Fig. 7 illustrates a dynamic balancing machine for testing automobile crank-shafts previously placed in perfect static balance. The information furnished by the machine is simply the relative displacement (added distance) of one of the pairs of rods of the squirrel cage. By referring to a set of specially prepared tables, similar to the one shown in Fig. 8, the operator can pick out readily the necessary directions as to how to remove a certain amount of metal from one of the cranks and how to drill the flange in order to secure perfect dynamic balance.

Fig. 9 shows a machine for balancing special blowers. If all such fans are of the same size, the directions will be given in the very easy form shown in Fig. 10. There can be no ambiguity in carrying out the instructions.

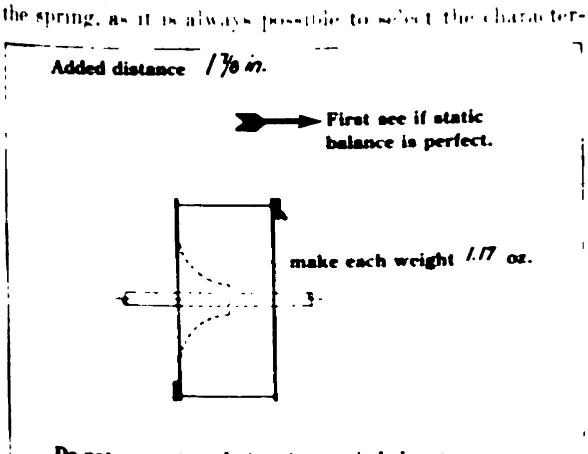

FIG. 9. DIRECTIONS FOR BALANCING BLOWER

It is not necessary to dwell on the extreme importance of testing a body for unbalance in its natural position and upon its own bearings. This machine in its very conception is adapted for testing under such conditions. The shaft in Fig. 7 is being tested in its own crank case.

The importance of static balance cannot be over-estimated. Fortunately, such a condition can be readily secured. Theoretically, one pair of rods in the squirrel cage, Fig. 5, of the machine would suffice, since the relative position of the rods to the body being tested can be altered readily through the transmission (chain drive shown in Fig. 4). For convenience, however, it is best to have three or four pairs of rods, and even then it is sometimes necessary to change the angular position of the cage so that the balancing can be done by one pair of rods and not two, as often happens at the beginning of a test.

Fig. 10 illustrates a somewhat special case. Here the correcting couple *c d*, numerically equal to the disturbing couple *a b*, has been introduced for some local reason in the manner shown; that is, the action of the correcting couple seems to be in a region rather remote from that of the disturbing couple. This simply means that the two actions will neutralize through (and within) the body. Even in such an extreme case, however, the supports or foundations of such an apparatus will be found to experience no vibratory effect.

Some of the Troubles of a Small-Shop Foreman

By H. E. Billton

I have been trying for nine years to get a clock in my department and have just got one. We have a good many short jobs that have to be charged up, and it is essential to know the time spent on them. There is a clock on a stack four or five hundred feet away. When it snows or there is a fog, I have to guess at the time. When the sun hits this clock from a certain angle, we cannot see the face for about two hours, owing to the reflection, which is so strong that we are obliged to have shades on the northwest windows. For these reasons there has been time enough lost to buy a carload of clocks. It seems strange that a company cannot see these little things and their importance.

I have a lot of old men working for me. I interceded for one—the fellow who wears ten-cent eyeglasses—and had him promoted to take charge of the time clocks. This makes a good job for an old man, and he feels that he is monarch of all he surveys.

Most of my men have left and gone into shops where they are working eight or nine hours a day, and they are making as much, if not more, money. About the only help I can keep consists of apprentice boys (who are under contract) and old men. I try to get along this way; but it looks as if we should have to reduce our working hours to get some good men, and the quicker the company wakes up to this fact the better. On Saturday we start work at 6 a.m.; and you can't get young men to go to work at this unreasonable hour, when they can start work in some other shop at 7 a.m. with just as much pay.

But we are having other troubles. Last month a customer sent in a brass model pattern and wanted a dozen castings made, so that he could make his jigs. We sent the castings; he reported that they were all right and ordered us to go ahead and make up full gates of them, which we did, and sent him several thousand pounds of castings.

What a call-down we got from that customer! It seems that he used the first dozen castings, made from the model, to make his jigs by; we used the same models to get our brass pattern castings from, which made another shrinkage, and of course the castings came too short. When they came out of his jigs, the holes looked as if they were made by one who had freely imbibed.

Of course, they tried to put it up to the pattern department, but it has a boss who is not asleep on his job. He came back and said that he did not know anything about their making a dozen castings from the model, so that the customer could make his jig.

He said any d— f— that knew anything at all about the foundry business should have informed his department that there had been castings made from this model to make jigs by. If he had known this, he would have made proper allowance for shrinkage; and besides he asked the assistant superintendent if it was all right to use this model for patterns, and he said it was.

What can we expect if assistants with no mechanical ability are put in charge? They cause all kinds of trouble and losses, not only for the company that employs them, but for the customer as well, and every mechanic gets disgusted with them and eventually leaves. Then the company wonders why.

Wanted--Data on Cylinder and Piston Grinding

By A. D. Marcotte

While having had considerable experience in building gasoline engines, I have been puzzled at various times by finding cylinders out of round, which I attribute to the action of the metal in the cylinder and possibly somewhat to the vibration of the machines employed.

I should like to hear from experienced brother mechanics who have had these troubles and have overcome them by grinding the cylinders after they are bored and seasoned. Is it possible to arrange a motor-driven grinder on a horizontal boring-mill bar and grind cylinders of this kind after they are bored?

I am also interested in getting opinions as to the practical allowance for piston play in gas-engine cylinders. In other words, how much smaller should the piston be made than the cylinder for best results, when both cylinders and pistons have been ground true?

[We are publishing the foregoing request for information in the hope that it may bring out some helpful and interesting experience on the subject of cylinder grinding.—Editor.]

Ground Asbestos and Oil for Babbitting Putty

Anyone having much babbitting to do knows what trouble it is to keep the clay of the right consistency for "mudding up" when pouring. The use of ground asbestos mixed with engine oil is reported by J. M. Ericson to give fine results. It never gets hard and is always ready for use.

Principles and Practice of Dynamic Balance

COMMENTS AND DISCUSSIONS

SYNOPSIS—A number of comments and discussions on N. W. Akimoff's paper on "Dynamic Balancing," given at the spring meeting of the American Society of Mechanical Engineers. The novelty of his machine and methods is recognized and appreciated, although not all who offered discussion agree that it is first necessary to secure static balance when putting a machine part in dynamic balance.

[On page 857 is reprinted a paper on "Principles and Practice of Dynamic Balance," presented at the spring meeting of the American Society of Mechanical Engineers by N. W. Akimoff. There was considerable discussion of this important engineering and shop subject. Most of these comments have been gathered together here, with some condensation because of the limitations of space.

A discussion by F. A. Halsey, treating of the lag of unbalanced revolving bodies, is not included, for this subject was carefully gone into in the *American Machinist*, Vol. 41, p. 1157.—Editor.]

The Two Classes of Balancing Machines

BY F. HYMANS

Mr. Akimoff's paper will not fail to arouse profound interest in the engineering profession both on account of the simple and clear manner of presentation and the ingenious machine it discloses. In addition to the detrimental effects of an unbalanced rotating body as enumerated in Mr. Akimoff's paper, loss of power should be mentioned in causing and maintaining vibrations of the structure supporting the body.

This has been demonstrated by Sommerfeld ("Zeitschrift des Vereins deutscher Ingenieure," 1902) in his experiments with a small electric motor that carried on its shaft an eccentric weight. Placing the motor on a table, it was found that at 310 r.p.m. the table began to execute horizontal vibrations. In an endeavor to increase the motor speed the voltage impressed on the armature was raised. It was found, however, that the voltage could be considerably increased without causing any increase in the speed of the motor, and the increased power consumption was absorbed in maintaining the vibrations of the table. Under perfect balance of a body rotating free around a horizontal axis, for instance, is understood the condition when there is no bearing pressure, save that due to its weight. If it were possible therefore to measure directly the bearing pressure and its direction relative to the body, we should have the simplest form of a balancing machine and should directly be in a position to determine the corrections necessary to bring about perfect balance. Unfortunately, direct measurement of forces is rarely possible.

All balancing machines serve, as a rule, to bring about a dynamic balance after the body has first been statically balanced. This is not due to any impossibility to determine the corrective means for static as well as dynamic balance simultaneously on one and the same machine. However, the problem is considerably simplified if static balance is first secured, as in a body so balanced the resultant of the centrifugal forces to which its particles are subject is a couple only, instead of a couple and a force, as in a body entirely unbalanced. In order to detect the plane and magnitude of the couple, the machine must be arranged so that the couple can manifest itself in motion of some sort. Incidentally then a dynamic balancing machine affords a plain demonstration of what a rotating body only statically balanced may cause when the conditions are favorable.

Considering the balancing machines of the vibrating type more in particular, we can broadly divide them into two classes: First, machines in which the vibrations excited by the centrifugal couple are directly employed to determine its plane of action, as is the case with nearly all balancing machines existing heretofore (see also the description of the Lavaczeck machine in the "Journal" of the American Society of Mechanical Engineers, March, 1916, page 268); second, machines in which the vibrations are merely employed to indicate lack of balance, of which class Mr. Akimoff's machine is to date the sole representative.

Referring to the first-mentioned class, the position of the plane of unbalance is always determined by observing the position of the body at the instant of maximum amplitude of the oscillations. When the body is rotated at a sufficiently low speed, so that the period of rotation is very large as compared with the period of free vibration of the system, the oscillations of the machine will be in phase with the exciting forces and it would be simple to determine accurately the plane and even the magnitude of the centrifugal couple. A machine so arranged would, however, not be sensitive enough for the purpose. On the other hand, when the body is rotated at a speed at which the period of free vibration of the system is no longer negligible as compared with the period of rotation, there is a phase of difference, due to mechanical friction and damping forces, between exciting forces and oscillations. As the amount of this phase difference is uncertain, the plane of unbalance can only be determined approximately. In addition, the oscillations can no longer be employed to calculate the magnitude of the centrifugal couple.

In the Akimoff machine it is quite immaterial if there is phase difference between oscillations and exciting forces. As described, an additional couple is introduced, which can be so adjusted in phase and magnitude that the vibrations of the balancing machine vanish. It affords therefore at once the means to determine exactly both the plane and the amount of unbalance. Disturbing influences such as "weakness" of the shaft of the rotating body can practically be wholly eliminated by selecting a spring of a flexibility which is large as compared with that of the shaft. In other words, by the proper selection of the spring the speed of rotation of the balancing machine can be made sufficiently low so that the transverse vibrations which the centrifugal couple tends to set up in the shaft of the rotating body will be practically of no effect on the beam of the balancing machine.

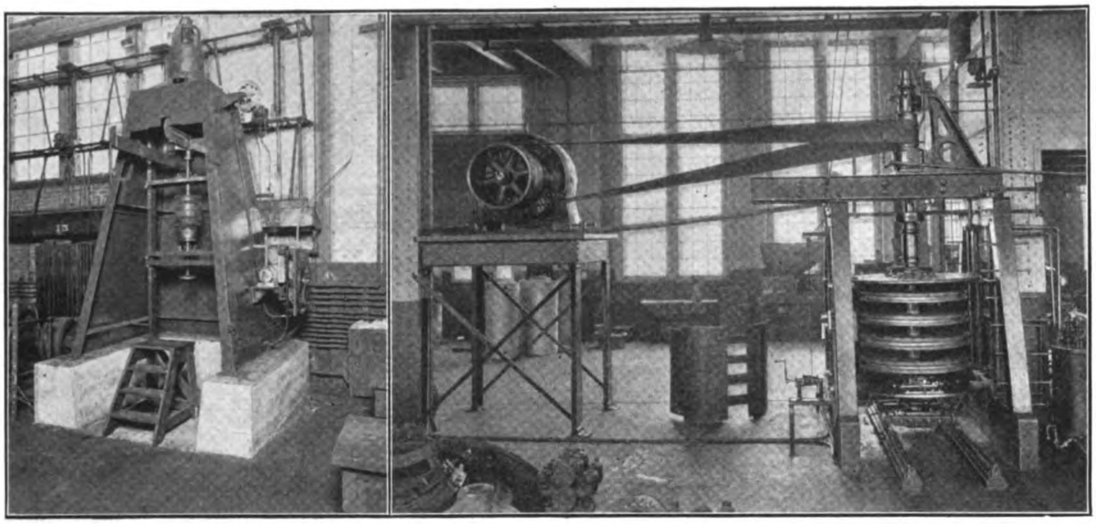
Looking at it from an angle, it must be conceded that Mr. Akimoff has found a complete and practical solution of the problem, and with the advent of a machine with which a perfect balance can be obtained easily and accurately there should be no reason why a perfect balance should not become a standard requirement for nearly all classes of rotating machinery.

Vertical and Horizontal Balancing Machines

BY JOHN RIDDELL

A good deal has been said and written on the dynamic balancing of machine parts, and therefore it is not an easy thing to add new matter to the subject. Dynamic balancing has of course been practiced whenever it has been necessary to do so, and while the old-time miller probably did not call his action by that name when he balanced a millstone, it was, nevertheless, the proper term for what he did. The man that could do this work was considered of importance.

The balancing of millstones was no doubt one of the earliest problems of dynamic balancing, and of course the laws governing the work were the same then as they are at the present time. Only within recent years has the subject received the attention that it merits. The reason for this is not hard to find when we notice the steadily increasing speeds employed in modern machinery, such as steam turbines, gas engines, woodworking machinery, etc.



FIGS. 1 AND 2. TWO FORMS OF VERTICAL DYNAMIC BALANCING MACHINES

The subject of dynamic balancing is at the present time a thing uppermost in the mind of the manufacturer of high-speed machinery, and it must be said that a great deal of ingenuity has been shown in dealing with the question, such as the introduction of specially designed machines for the purpose and also a better understanding of the underlying principles governing the operation.

The introduction of specially designed machines with which to give parts a dynamic balance was caused more by a desire to cheapen the operation of balancing than by the expectation of producing a better balance than it was possible to get when balancing the rotor in its own bearings—that is, in the machine of which it is a part. While unquestionably the latter method produces as good results as can be obtained by any other method, it is not the most economical way to do the work, especially when production requirements call for the rotor to be ready for operation when the other parts of the machine are finished.

The use of balancing machines has now become universal, and the results are generally satisfactory, both as regards the quality of work produced and in the matter of economy. It becomes simply a matter of selecting the type of machine deemed most suitable for the particular kind of work to be done, and more especially depending on the degree of perfection to which the rotor should be balanced.

To me, it appears as though the present-day balancing machines can be divided into two distinct classes: First, that which carries the rotor in a vertical position suspended from an overhead drive by means of a cable or a flexible shaft; and, second, the class which carries the rotor in a horizontal position, running in either ordinary bearings or on rollers carried in suitable holders that can rock against springs or buffers of some description—in other words, bearings that possess some degree of flexibility.

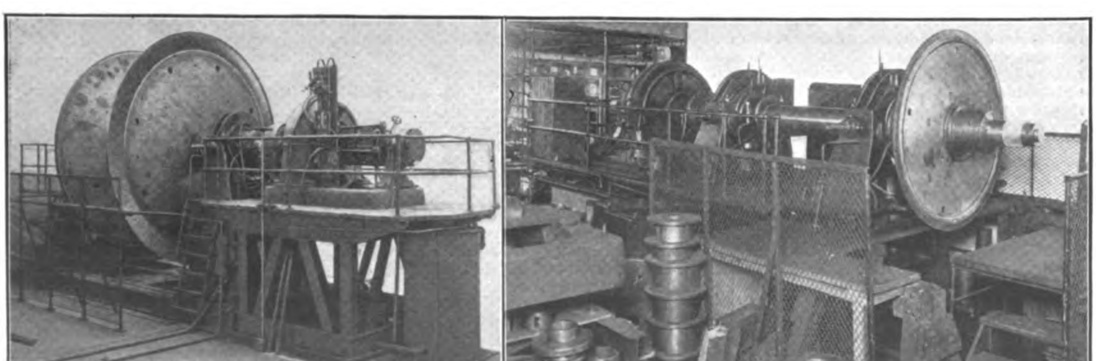
My experience is that the vertical type of balancing machine gives the most nearly perfect balance, owing, no doubt, to the fact that there are no bearings to influence the running of the rotor; also, since the rotor is suspended, it can run out and show the amount "out" much more easily and to a greater degree than if supported in bearings. The cost of balancing in the vertical-type machine is, at least for heavy work, somewhat greater than that of balancing in a horizontal machine, partly on account of attaching the work to be balanced to the machine.

Another reason is that the machine is so much more sensitive than one of the horizontal type that the very balancing operation becomes somewhat more delicate, and it no doubt often is the case that the refinement obtainable on a vertical balancing machine is not needed for some kinds of work. In such cases it is proper to use the horizontal type of machine; but one thing should be remembered, and that is that when it is desired to balance a rotor the service speed of which is somewhere near its critical speed it is much easier to do the balancing in the vertical machine than in a machine of the horizontal type.

It is my opinion that, in order to give a body a perfect dynamic balance, it is necessary to do this at a speed at least equal to the maximum speed at which it is to be operated in actual service, as it is quite possible to have an apparently perfect dynamic balance at one speed and then find that the balance is imperfect at higher speeds. Whereas, if a body is in perfect balance at its highest speed, it will also prove to be in perfect balance at all lower speeds.

I also wish to say that it is a useless and wasteful practice, except in a very few specific cases, to give a body a static balance if a dynamic balance is to be finally produced.

Figs. 1 to 4 show machines used by the General Electric Co. for obtaining dynamic balance of electric-machine parts.



FIGS 3 AND 4. TWO FORMS OF HORIZONTAL DYNAMIC BALANCING MACHINES

Balancing Practice of the Westinghouse Companies

By Francis Hodgkinson

Mr Akimoff describes a device of a very ingenious character for dynamically balancing rotating bodies It seems to me, however, that it is open to the objection that the member to be dynamically balanced must be put in perfect static balance before being balanced by the means described. This in the case of heavy revolving bodies is quite difficult and is not to be satisfactorily attained by the usual method of rolling the body on ways or the like. Therefore, it seems to me that a machine to do dynamic balancing should by its means render possible the elimination of errors in static balance.

Mr. Akimoff points out that he is enabled to move the rods of his balancing machine axially while the cage is in rotation, but withholds his method for accomplishing this and the details of the cage

It would seem evident that the spring support at one end of his frame should have a natural period of oscillation equal to the period of revolution of the body being balanced. This, of course, would mean a different spring for every different weight of body applied, which would require some calculation in advance of doing the work, where there is a great variety of things to be balanced

Mr. Akimoff speaks very disparagingly of the older method of securing dynamic balance--that is, running the body at a reasonably high speed and marking the shaft and determining the "high spots" He says they can only serve to indicate that the body is out of balance As a matter of fact a very well organized system of adding weights may be employed that renders both the static and dynamic balancing of the body a simple operation. One of the hardships of the matter, however, is that the adding of weights or drilling, as the case may be, must be done more or less piecemeal, and the time occupied by speeding up and shutting down occasions a rather severe loss of time.

I said previously that the static balance is not easily obtained. In this I referred particularly to bodies such as revolving fields of great weight where to mount these on ways, giving them a rolling balance, is unsatisfactory because in spite of the surfaces being hardened and made as level as possible the journals will sink into the ways to a slight degree, so extreme sensitiveness cannot be obtained, because of the field having to run up hill

It has been frequently found in the case of very large fields that an approximate static balance may be obtained by smearing the bearing surface and journals well with a heavy cylinder oil, dropping the field into the bearings and quickly removing the chains, when the friction would be so low that the field would respond to an error in static balance better than with the previously described method of rolling on ways. Of course, the field must not be allowed to stand more than a fraction of a minute, or until the oil film has been squeezed out, for then, of course, the friction becomes very material.

So far as steam turbines are concerned, it has not been the practice of the company with which I am associated to resort to dynamic balancing except in a few extreme cases. Turbines generally are comprised of a drum or quill to which are attached the spindle ends and journals. This drum has secured to it a certain number of disks or rings. Generally the speed of the drum is low, so that ordinarily static balancing—that is, rolling it on ways is sufficient Further, the disks or rings are short in their axial length as compared with their diameter, and a careful static balancing of these is found to be all sufficient For balancing these disks and rings a special static-balancing machine was devised many years ago and has been in continual use Inasmuch as this paper is confined to the subject of "dynamic balancing" its description is out of place. A description of it was published in the "American Machinist," Vol 35, p 59. I might further add that with this machine a disk weighing 4,000 or 5,000 lb. may be given a static balance within an error of half an ounce.

I previously stated that there is on organized system available for balancing bodies, which Mr Akimoff disparages and which he has illustrated in Fig 2 It may perhaps be of interest to describe this system, although the description is rather more of instruction to a mechanic than technical data to our society.

The bearings being mounted on springs as described is not really a necessity The bearings employed for large turbine rotors have enough clearance and oil-film thickness to give sufficient amplitude of vibration to determine the "high spots," although in building a balancing machine, I would prefer to mount the bearings on springs, or their equivalent, but taking care that the natural period of oscillation of the bearings and the rotary masses be higher than that of the running speed to be employed in balancing. It does not matter at what speed the balancing is done any more than it would with the machine Mr. Akimoff described. It is only necessary to run it fast enough so that the vibration due to error in the balancing is well in evidence. It, however, is necessary that marks be applied to the shaft, always at the same speed, because the angle between the error in the balance and the mark on the shaft will vary with different speeds. It is invariably found that the error in balance will be a number of angular degrees behind the mark, this angle becoming less with the speed and greater with more rigid shafts.

Inasmuch as it is the centrifugal couple which is to be eliminated and the bodies are of such proportions—that is, great relative axial length—and the balancing at each end must be done independently and as in the case of Mr. Akimoff's machine, it is impossible to eliminate centrifugal couples such as he illustrates in Fig. 11. It is found in practice that it is undesirable to work on more than one end at a time, and the end should be first selected that is most out of balance, this to be judged by the degree of eccentricity of the path of the shaft rather than in shaking of pedestals, bedplates and such. Having marked the shaft at each end, a mark is made that may be used for future reference, and a temporary weight is added, as judgment would dictate, some degrees behind the mark. When the machine is again speeded up, it may be found that the balance may be better, but the position of the mark has changed. If this is so, an additional weight should be added or the original weight have its angular position moved so as to maintain the mark in its original position, continuing the operation, one end or the other, whichever has the most eccentric path. This process is carried on, and if the mark is maintained in the original position, it will be found finally that a weight added will throw this mark 180 deg. away from its original position, when the weights are then slightly in excess of that required for perfect balance, and only require to be slightly reduced.

By such a means both error in static balance and the centrifugal couple are simultaneously eliminated. Balancing frequently has to be performed in the field—when it is successfully carried out in its own bearings and with no knowledge as to the condition of static balance. Plainly, should the marks appear at each end on opposite sides of the shaft and the body run with similar eccentricity at each end, it would be inferred that the body was in static balance, only requiring the correction of the centrifugal couple.

Generally speaking, it is the practice of the Westinghouse companies to employ this method for all larger revolving fields, as well as for the occasional time when a turbine rotor may need dynamic balancing because some element of it is, due to some error, out of static balance.

Slow-Speed Test Is Not Conclusive

By E. J. Loring

I would define a body as dynamically balanced when its unconstrained axis of rotation is concentric with its journals. The method proposed assumes perfect static balance; but dynamic-balance conditions are far more sensitive, because a slight static unbalance is greatly magnified at high speed. I do not agree that static balance is easily obtained; on the contrary, unbalance always persists to some degree and must be provided for in the dynamic-balancing operation. A body dynamically unbalanced does not usually show high spots diametrically opposite at the two ends, as it would if a simple couple were acting.

The wire-rope suspension is not irrational. It supports the shaft with far less constraint than any rigid bearing, transforms a "rigid shaft" construction to "flexible shaft" conditions and leaves the rotating body more nearly free to rotate on its own principal axis in space.

When provision is made for attaching balancing weights in two well-separated planes between the bearings of a two-bearing shaft, it is possible to determine the position and amount of added weight required in the nearer plane to each bearing in not more than three "shots," and with this information for each balancing plane the proper weight and position for each plane to clear both bearings simultaneously may be found by a simple calculation.

A slow-speed test is by no means conclusive. A body in dynamic balance at 400 r.p.m. may be dangerously far from balance at 3,000 r.p.m.; when corrected for 400 r.p.m. it is

safer than when only statically balanced, but its balance is never fully proved at less than its full speed.

I would be interested to know how the correct plane of displaced rods is picked out from the behavior of the beam and the rotating body. Is it by a definite rule or by selection and trial?

Early Attempts at Obtaining Dynamic Balance

By H. P. Fairfield

While the question of running balance is yet much discussed, commercially considered it would seem to be fairly solved. The necessity of providing some means for indicating a running balance I believe to have arisen first in the cases of the cutter heads of woodworking machines and in machines used for threshing grain. In these machines when placed upon the market a generation or two ago the cylinders upon which the knives or cutters were mounted in the wood-planing machines were given a considerable rotative speed. This was also true in the case of the threshing machine, where the teeth that beat the grain from the straw were attached to a cylindrical drum which was made to rotate rapidly. The first attempt at solving this question, so far as I know, was to place the piece to be tested in a pair of boxes that were hung by wire, or other flexible connections, from the ceiling. The part being tested was then rotated at speed, its action noted and indicated by the operator, who made the necessary weight changes to give the required effect. (In the Norton machine the pendulums are inverted.)

What Mr. Norton has accomplished in his balance-indicating machine is to attack the problem of balancing rotating bodies by treating the subject as a problem of running balance only, giving no attention to questions of standing balance. It is believed that his machine was the first which provided a means by which the workmen could locate the exact position of the error of balance. This is accomplished by designing and constructing a machine that provides means for reversing the directions of rotation, thus eliminating all guessing as to the amount of lag in indicating. This practically eliminates the question of judgment in operating and brings it to that of an exact science, rendering it possible to place a rotating body in commercially exact balance if the removing of, or adding to, of weight is carefully done.

Another peculiar feature of this machine over some others is that nothing foreign is mounted upon the body being tested, thus confining the test to the piece itself. Also with this machine the critical speed for the piece can be noted as the exact speed at which the high spot passes from the heavy to the light side. [The Norton machine was fully described in the "American Machinist," Vol. 32, p. 1023.]

It may be well to take note of several practical points that have been well proved in practice:

A. That while a body placed in static balance may be decidedly out of running balance, one that is placed in running balance must also be in static balance.

B. Exact symmetry of form must not be taken to mean that the machine part is in running balance.

C. A machine part put in running balance at any speed is certainly in running balance at any other speed, if it is not distorted from its true axial conditions.

This fact renders it possible, therefore, to rotate the part which is being tested at any speed desired that does not distort or spring it.

It will be admitted, I think, by all users of speed machinery that all rotating parts should be placed in exact running balance if the machine is to perform its functions quietly.

Two Pertinent Questions

By T. A. Bryson

Mr. Akimoff explains that it is extremely difficult to ascertain the underlying idea of apparatus in which the axis of the body is pivoted at one point and that the dynamics of the case is much more difficult of solution than that of a body having a fixed axis. Is not the action of the device shown similar to the former case, since all axial motions of the body are transmitted to the hinged frame?

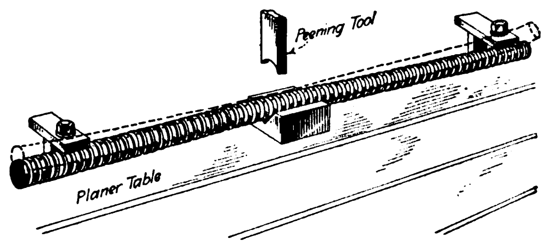
It would seem that much might be gained by providing for close adjustment of the axial plane of the balancing weights while the cage is in rotation, thus performing both operations without stopping to change the angular position of the cage. Is the chain and gear drive free from vibrations that would affect the results?

Straightening a Long Screw

By D. A. Hampson

A special 3-in. screw that had been bent in transit was brought in to be straightened. As the threaded part was 20 ft. long and the truth of the work must be undoubted, it was no usual job. The bend was ascertained to be a decided "kink" not far from the middle.

The first step, after definitely locating the bend, was to lay the screw in a V-block on a long planer, with the bend right in the block and the screw in the position shown exaggerated by the dotted lines. Clamps were put on each side of the block and the screw drawn down until the



STRAIGHTENING A LONG SCREW

bend was in the opposite direction. Dents and bruises on the thread could not be tolerated, so leather liners were used in the block and under the clamps.

Springing the screw to line was not attempted. It was sprung beyond straight while the metal at the bend was swelled enough by peening to give a set to the screw. No peening was done on the face of the screw, but a concave-faced tool was made that could be used on the bottom of the threads. Three or four trials were made before a perfect job was secured, but it was done very easily and proved much less formidable than it first appeared.

The Group Insurance Plan

In adopting the group insurance plan to cover its employees the president of the Chain Belt Co., Milwaukee, Wis., made the following statement:

In order to show our appreciation of loyal and efficient service, I have been instructed by the board of directors to announce that the Chain Belt Co. has contracted with the Equitable Life Assurance Society to insure the lives of those between the ages of 21 and 65 who have been in our employ continuously for one year or more on Apr. 20, 1916, for the sum of $500 each and those who had been in our employ continuously for two years on Apr. 20, 1916, for the sum of $1,000 each. In the case of the employee who has been with the company for one year a substitute certificate for $1,000 will be given her or him when the term of continuous employment will have reached the two-year period. All new employees over 21 years of age will receive a certificate for $500 upon completing one year's service. In the event of an employee's leaving the company's employ the insurance, of course, expires automatically.

This is term insurance and is given without charge, and in the event of death while the policy is in force the beneficiary named will be paid the amount of the policy by the insurance company. It will be issued for the year ending Apr. 20, 1917, but it is our intention to renew from year to year, unless in the judgment of the board of directors it shall prove unsatisfactory or experience suggests amendment. The insurance company is now preparing the policy and making out individual certificates of insurance, which will be delivered in a few days.

The officers of this company are not only interested in you and the women and men in our employ, but also in the welfare of those dependent upon you and feel that in this manner they can show that interest to be real and substantial.

Letters from Practical Men

Making Accurate Templets

When the manufacture of shells in large quantities first began in this country, I had some flat templets to make for gaging the form of shells. At that time I was satisfied to fit them to a master by using the method shown by Mr. Van Deventer on page 142, Vol. 44. But when flat gages began to come along in lots of 50 to 100, I found it tiresome to hold them up toward the window in fitting, so made the rig shown in Fig. 1.

It is an ordinary wooden box, about 6x6x9 in., with the ends removed. On the rear I nailed an ordinary tin light-shade containing an 8-c.p. electric light. The front end is a piece of heavy plate glass, with oiled paper

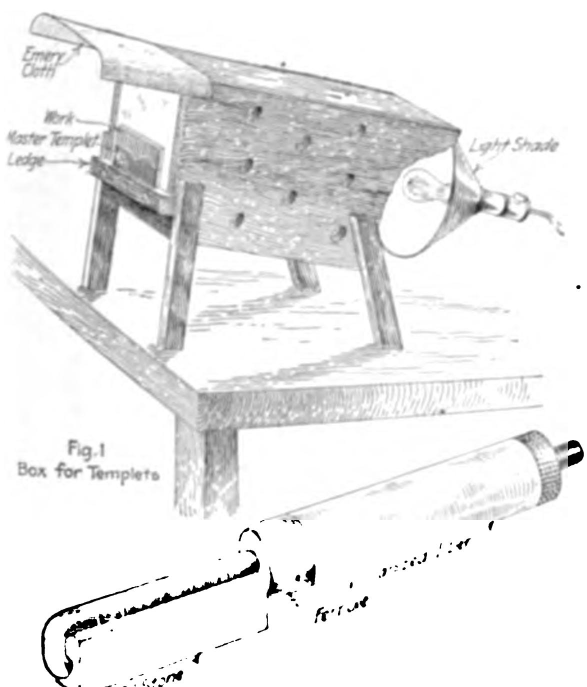


Fig. 1 Box for Templets

Fig. 2. Handle for Oil Stones

MAKING ACCURATE TEMPLETS

behind it. A ledge runs across the front, to support the master templet. There is a projecting hood out over the glass, formed by nailing a sheet of emery cloth to the box. I cut a large V-shaped opening and bored a number of holes on each side of the box, for ventilation, so that the electric light would not heat the plate glass or templet. The legs bring the box up to the proper height and angle to meet the line of vision as I sit at the bench. I find that I can fit gages much more accurately and quickly with this rig than formerly.

In finishing hardened gages I use a number of India oil stones. I keep handy a shallow tin containing a kerosene-soaked felt pad. Occasionally wiping my oil stones across this pad keeps them clean and free-cutting. The flat surface of an oil stone will soon wear round or otherwise get out of shape. To restore the flat surface of the stones, I sprinkle No. 90 emery and a little kerosene on a piece of plate glass and lap the oil stone perfectly flat on it. This is the quickest method I know of to restore a flat surface and at the same time retain the fast cutting quality of an oil stone.

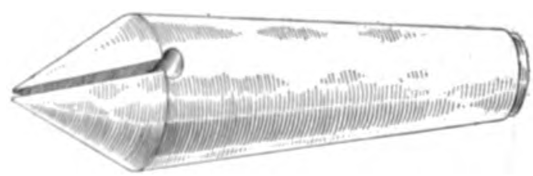
To make use of short pieces of broken oil stones, I use the handle, Fig. 2. It allows me to work up short pieces of oil stones that could not conveniently be held in the fingers. The hook passes through the knurled handle and has a long thread at the end, permitting quite a range of adjustment, so that oil stones of various lengths may be used. HERBERT M. DARLING.

Greenfield, Mass.

A Center Scraper

The accompanying illustration shows a center scraper that has been found useful in the toolroom where lathe arbors are made, the object of the tool being to correct and smooth the center in the arbors after they have been first drilled and centered in the usual way.

The center scraper is similar to a lathe center. It must be made of a good carbon steel; and before it is



A CENTER SCRAPER

hardened, a hole must be drilled as shown and a $\frac{1}{32}$-in. saw cut put in. After it is hardened, the point is ground to the angle required.

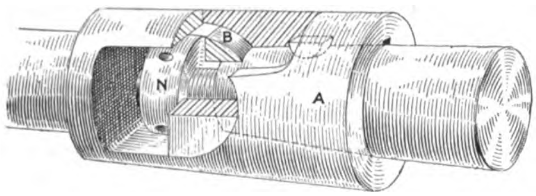
When the scraper is in use, the pressure causes the center to close slightly at the slit and thus makes the edges of the saw slit become cutting edges on either side. While the cutter is effective for the purpose named, it is not intended to be used to produce the center completely. W. SMITH.

Birmingham, England.

Connecting a Conical Shaft End to a Coupling

Some time ago I was confronted by the following problem: The end of a shaft of the design illustrated had to be connected to a coupling. As it was only for an experiment, no alterations on the shaft were allowed; but the connection had to be made absolutely safe, because the machine was required to run alternately in each direction. When I asked for instructions, I was told: "It is only temporary; fasten it any old way; glue it on, if you like, etc."

The inexpensive construction illustrated was the outcome. The sleeve A is made of machine steel. A hole is drilled crosswise and enlarged, as shown. The



CONNECTING A CONICAL SHAFT END TO A COUPLING

piece has a good bearing in it and is self-adjusting, as it has the same radius as the opening in *A*. The nut *N* will, when screwed backward, pull the sleeve off, thus serving a double purpose.

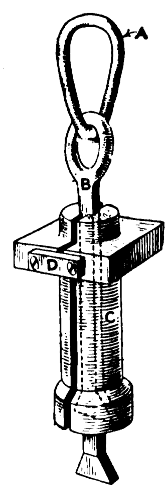
All the pieces were casehardened and formed a very solid, easily exchangeable connection. S. KOPSCH.

Plainfield, N. J.

Lifting Device for High-Explosive Shells

The illustration shows a lifting device for use on high-explosive shells that have the nose end open. The construction of this contrivance and the method of using it are as follows:

The part *A* is a steel ring welded into the eye of part *B*. This ring goes over the crane hook. The part *C* is of a very tough grade of bronze, cast in one piece. It is machined on the outside, then split with a ⅛-in. saw and milled after the slot that receives part *B* has been split. The reason that this piece is made of bronze is to prevent any marring of the threads in the nose end of the shell. If this device is used on shells before tapping, the part *C* could just as well be made of steel, assuring a much longer life. Part *D* consists of two pieces of cold-rolled steel, fastened on the sides of part *C* so as to keep the loose pieces from dropping off when the device is outside of the shell. The screws that hold these pieces on should bottom, so as to leave part *C* free to move. In putting this device into the shell the part *C* is held up against the eye on part *B* until the shoulder on part *C* rests on the shell. When the crane starts to lift, part *C* is caused to expand on the inside of the shell by the action of the taper on part *B*. The heavier the load the tighter the device will hold.



LIFTING DEVICE FOR EXPLOSIVE SHELLS

This device can be used for picking up shells from a horizontal position as well as from a vertical position. If it is desired to pick up more than one shell at a time, all that is necessary is to splice a cable in part *A*, making each cable 4 in. longer than the preceding one. Having these cables of different lengths allows the hooker-on time enough to adjust the device, using the shortest cable before the next one begins to lift. In setting the shells down, the operator will have time enough to steady the shell on the longest cable before the others touch the floor.

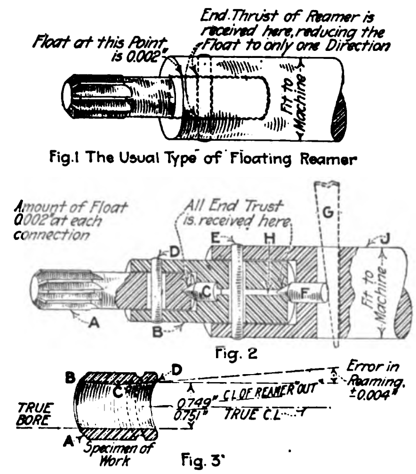
In removing this device lift part *C* up against the eye of part *B*, in this manner removing the whole thing from the shell. Making a hitch with this device (lifting single shells) can be done as quickly as the crane operator can reverse the direction of his hook.

Erie, Penn. ARTHUR A. MERRY.

Compound Float for Reamers

Fig. 1 shows what seems to be a general and serious fault of the usual type of floating reamer. The design in Fig. 2 is a solution of the problem. In Fig. 3 is shown a specimen of work.

The operations are (1) drill and form-turn, (2) nick and turn chamfer at *A*, (3) ream, (4) cut off. There is a "float" of 0.002 in. given the reamer, to compensate for the inaccuracy of the machine and produce a straight hole. The general arrangement is shown in Fig. 1. Of course, as the reamer enters the drilled hole, it simply becomes "cramped" all the more, since the end thrust is taken by the driving pin, prohibiting entirely



A COMPOUND FLOAT FOR REAMERS

all float in a direction corresponding with the longitudinal center line of the pin. The result of floating a reamer tap or any other tool in this way is seen at *B*, *C* and *D*, Fig. 3. The correction makes a great deal of extra work for the internal grinder. Now, Fig. 2 shows a method that is simple and far better. This compound float is in effect two simple universal joints.

Suppose the reamer enters the drilled hole 0.0025 in. out of line. The reamer *A* is centered by the drilled hole. A free universal float of the reamer in the bushing *B* is permitted by the center thrust bearing *C* and the elliptical pin hole, the pin *D* being used for driving only. As the drilled hole is 0.0025 in. out of line, an angle is formed between the drilled hole and the center bearing *C*.

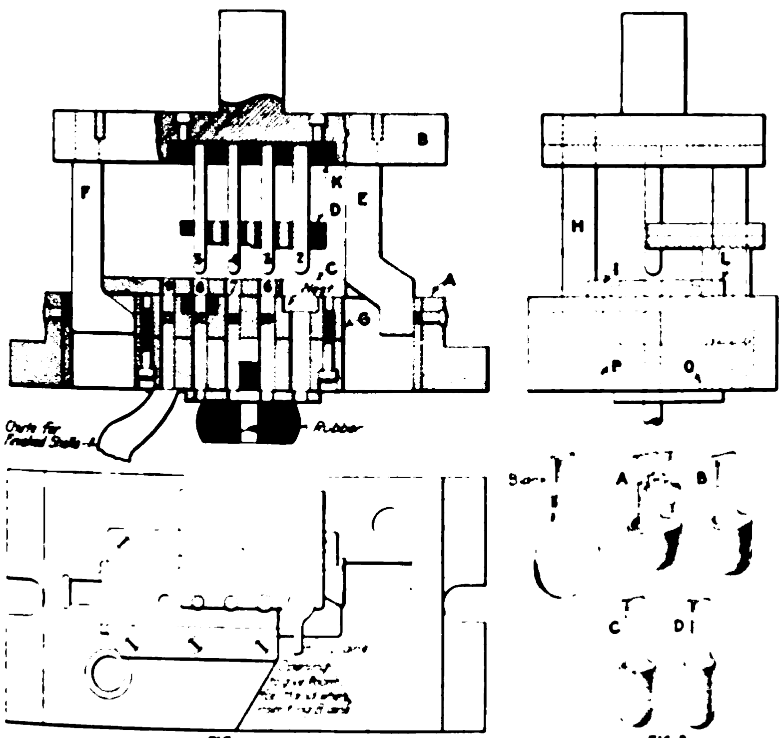
This is where the trouble arises. Now, as the angle is produced by the action of the reamer in reaming the hole, the second joint becomes a counteracting agent and allows the reamer to align itself with the drilled hole. *E* is the main driving pin, and like *D* is a taper drive fit. *F* is the main center bearing and is removed

for grinding by means of the "drift" G, while the secondary center C is removed by driving through the centrally drilled hole H. J is the body of the tool holder and is fitted to the machine. J. B. MURPHY.

Plainfield, N. J.

Automatic Punch and Die for Tube Drawing

It may be of interest to some readers of the *American Machinist* to know how four tube-drawing operations have been converted into one. The illustration, Fig. 1, shows a sectional front view of the tool that I designed and built to produce the tubes shown in Fig. 2. I will mention only the new features of the device, and tool makers familiar with this kind of work will need but a few words in explanation of this punch and die.



AUTOMATIC PUNCH AND DIE FOR TUBE DRAWING

The blank, Fig. 2, is inserted in the die nest, as shown in Fig. 1. After the first operation is performed and stripped from the punch 2, the work will drop into the hole 6 of the sliding hopper C, Fig. 1. The slide is so adjusted that, as soon as the tube falls off the punch 2 into the sliding-hopper hole 6, it is carried over to the next drawing position 10 and drawn by punch 3, and so on until through 7, 8 and 9. After the tube is finished and pressed back in the upper position, it is again taken by the sliding hopper and carried into the knockout hole 13, whence it falls through the chute to a box, without being touched by hand. The sliding hopper is actuated by keys E and F and a spring (not shown).

In Fig. 1, A is the die shoe, K is the punch holder plate, B the punch holder and D the stripper. The pressure pad E carries knock-out pins to press the work out from the die. Aside from the guide-pin bushings G and P, all other parts shown are of regular design. The stock used was 0.016-in. German silver, and the finished tube was $\frac{3}{32}$ in. in outside diameter and about $\frac{5}{16}$ in. long.

I have made quite a number of similar dies to draw work of this nature, and they worked satisfactorily and saved time in combining the operations.

Bloomfield, N. J. CHARLES EISLER.

Balanced Production

One essential of stability, whether of equilibrium, aviation, central-station power, manufacturing success or diplomacy, is the quality termed balance. In distinctly technical and mechanical matters the need for balance is easily apparent; it has also importance in less tangible things. The troubles of management are not all directly technical; the major portion of them concern commercial, organizing and human aspects of production. Questions of coördination and of allocation of work cause troubles of no small order. To meet these difficulties requires the faculty of generalship, the provision in due time of material, avoidance of overlapping, economical employment of labor, precedence of work; and the mental characteristics needed are special and peculiar. A well-balanced works would keep all hands busy without delays; would insure that the foundry provided the casting on the instant; would insure raw material in regular but sufficient increments, always delivered to date; would abolish large stocks to save interest charges; and would be sure of all work passing in correct sequence to the dispatch floor. These are counsels of perfection unattainable in a material universe, dependent as they are upon promises and upon matters like transport, impossible to regulate. Unfortunately for our peace of mind such systematic perfection does not exist. Promises are unfilled, and delays in transit are common. Yet in spite of the relative importance of the matter we find works where jobs are held up for minor details under the control of the executive. The difference between fair profit and liquidation is apt to rest upon details that are cumulative in their effect. It needs vision and insight (to leave out so nontechnical a matter as imagination) besides system, to insure balance.

The larger the concern the more difficult it is to avoid wastage, to key up intensity of production. Delegation of authority often leads to conflicting aims between departments, and coördination is difficult to secure. In a transition stage from single to departmental control there is a danger zone to be crossed; such a condition affords many perplexing problems.

The balance between the various arms in an army corps is not less important than the same factor in the equipment and staff of a manufacturing concern. That it is possible to employ more men, each a potential source of profit, and lose money thereby is a commonplace of economics; the fact is perhaps less realized than it might

be. On the other hand, permanent overhead charges may by reduction of staff and output lead to total loss of profit. This second case is more generally realized than the first.

In a human sense, balance is a quality readily appreciated; the irrational enthusiast, the man who jumps to conclusions, is always a danger. Promotions frequently lead to discovery of a lack in this direction, and many a good man has been spoiled by want of balance. The most serious aspect of the matter at the moment is national. The entire resources of the country are being unified to a single end. We have now one huge enterprise in scattered locations. In a large works in normal times we realize difficulty (in what is by contrast a domestic sense) when material is overdue and delivery dates behind. The mere thought of 2,500 controlled establishments to be coördinated and planned for is one to appall and stagger any individual conversant with the troubles incidental to the management of 1,000 men.

So huge a control is intrinsically bound to result in lack of economy, in a strictly commercial sense. The generalship needed has never been trained to direct work on such a scale, to balance production so widespread. To effect commercial economy without wastage under the conditions is inconceivable; only the patriotism of an entire community could make the scheme workable.

Few of the many isolated cities stop to ponder upon the immensity of the task or are qualified to appreciate the difficulties to be faced or the results already achieved. There must be overlapping and lack of exact coördination. The size of the job in itself is sufficient to account for this, leaving aside forced production and intensity of effort. It is only the man experienced in handling a big labor force, shouldering the burdens incident thereto, who can even begin to appreciate the immensity of an entire nation under a single productive control.

An army in the field is not expected to be a strictly commercial affair, earning a percentage upon capital involved. It cannot be so conducted even upon peace lines; wastage is inevitable and allowable. Likewise, an industrial army organized in a time of crisis cannot be run like a retail shop. It is production, irrespective (more or less) of cost, that is required, and the economy or otherwise cannot be estimated until victory is achieved. Balance in production is often assumed to be cared for by system. In actuality, brains, patience, tact and numerous other intangible questions not directly technical enter into the equation. Neglect of a detached viewpoint is perhaps one of the surest harbingers of disaster in the usual business.

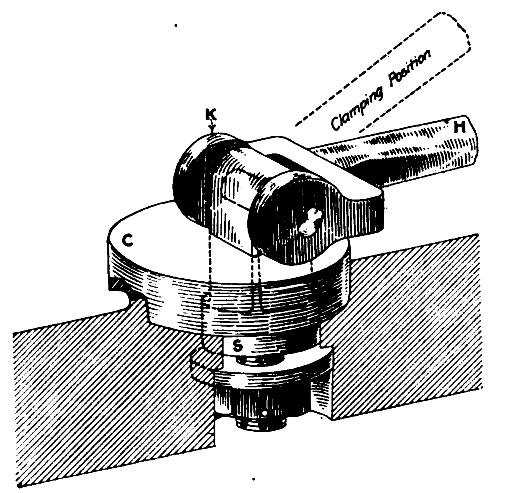
Never before in the history of the world has such a question of production arisen. The coördination needed to produce balance under existing conditions would tax the greatest mind, especially if it be held to strict accountability for economy in a commercial sense.

Tooting, S. W., England. A. L. Haas.

Locking Cam for Jigs

As applied to jig and fixture design, the cam used as a clamp presents some attractive features. It is a very simple element and may be strongly made. It is rapid in operation and readily understood by unskilled labor. Unfortunately, this type of cam must be designed with an angle of rise insuring it against slippage, if the work is to be held securely in place. Very little clamping movement can be had with this small angle, unless the cam is inordinately large. However, if means are provided to hold the cam rigidly, almost any movement can be secured. Such a cam can be used against rough surfaces and would work well on milling fixtures where difficulty is generally experienced with the nonlocking cam.

The cam shown possesses the favorable features mentioned and by a simple movement can be quickly and securely locked in the required position. The clamping cam C is free to move vertically on the square stud S;



A LOCKING CAM FOR JIGS

and when the handle H is horizontal, it can be rotated to any clamping position. When the desired position is reached, the handle is elevated, thus clamping the whole in place by means of the cam K. Of course, the stud S can be made with an integral head in place of the washer and nut, as shown. In many cases where trouble is being experienced this cam can be applied without altering the fixture. W. Burr Bennett.

Bridgeport, Conn.

Portable Sanitary Drinking "Fountains"

Here is how we have solved the sanitary drinking-fountain problem. Each man has a bottle or canteen and keeps it at his elbow or in a proper receptacle on ice, if he prefers ice water. It is somebody's job to keep the bottles filled and in proper condition. A sensible woman is best for this work—one who will keep things as clean as mother used to. This plan saves a trip of a mile or so for a drink, and the boys drink more water, too, when it is handy.

Once the cheerful idiot dropped beet juice in his bottle, and many an eye looked on that bottle while it was red. C. D. Michener.

Cœur d'Alene, Idaho.

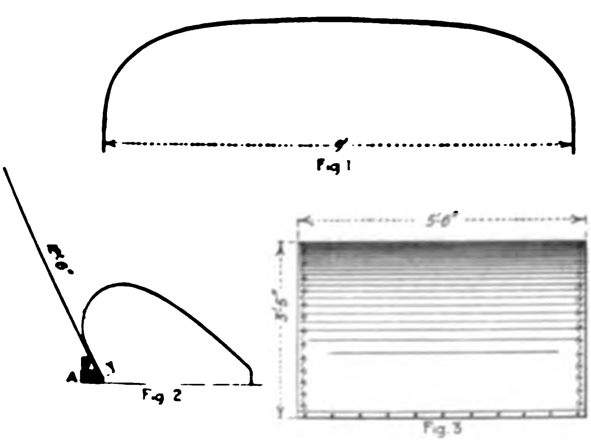
Manufacture of Lathes in United States—According to the preliminary statement by the Bureau of the Census showing the results of the 1914 study of the manufacture of leather in the United States, there was a decrease of 19.5 per cent. in the number of establishments between 1909 and 1914, but an increase of 12.1 per cent. in the value of the products.

Discussion of Previous Question

An Improvised Bending Form in a Railway Shop

After reading the article on page 281 I am prompted to show a simple bending form that I recently made for a number of hard-rolled bright-quality aluminum sheets. These were 12 ft. 6 in. in length, 5 ft. in width, 0.080 in. in thickness and were for the roof plates of some modern all-metal passenger cars.

The main point in favor of aluminum sheets for car construction is lightness. A sheet of aluminum 1 ft. square and 0.072 in. in thickness weighs less than 1 lb. (0.995 lb.), while steel weighs three times as much.



IMPROVISED SHEET-METAL BENDING FORM

This reduction in weight becomes of very great importance, particularly in suburban work, where stoppages are frequent.

In Fig. 1 is shown the contour desired and in Figs. 2 and 3 the side elevation and plan of the bending form. It was our desire to prevent, if possible, any further work being done on the sheet after bending. Had it been attempted to shape the sheets by some other method, such as with bending rolls or over iron bars, the sheets would have been likely to contain many irregularities on the surfaces. This is especially the case with hammering, for aluminum sheets will not stand anything like the severe treatment that may be given to steel sheets of the same thickness. When thin metal sheets, either of aluminum or steel, are painted for car construction, it is surprising how small defects are readily discernible on the surface.

The efficiency of the bending device enabled the work to be performed quickly, and exactness of contour was obtained without blemish. The cost of this form was very small. In fact, it paid for itself the first day.

It was simply constructed of steel sheets $\frac{1}{16}$ in. thick. Three pieces were required—two pieces for the ends and one for the center portion. They were cut to the required shape and dimensions, the center piece being bent to the contour of the side pieces and secured to them by $\frac{1}{4}$-in. cup head bolts. The ends were notched and then flanged at right angles on the inside for this purpose. The bottom edges were flanged at right angles on the outside, for fastening to the wooden floor by screws. A piece of wood was fixed to the floor as shown at *A*, Fig. 2, to prevent the turned-up edge or groove from damage and to support the process of bending.

A cast-iron bending block was at first suggested, but this would have necessitated an expensive wooden pattern in addition to the cost of a heavy casting. Then there was the inconvenience of having to wait several weeks for its delivery, whereas the sheet-metal bending form, with its simplicity and cheapness, enabled me to proceed bending the aluminum sheets on the following day. It was necessary to employ two workmen to manipulate the sheets satisfactorily, owing to their large dimensions. One end of a sheet was put into the groove, as at *B*, Fig. 2, and worked over the form as far as possible. The roof sheet was then taken out of the groove and the opposite end treated similarly.

Manchester, England. E. ANDREWS.

Quick-Acting Grinding Dog

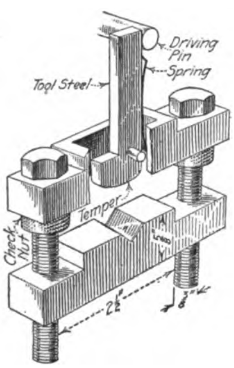
The quick-acting grinding dog illustrated and described by Harold E. Greene on page 558 reminds me of one which I made in 1909 and which I show herewith. I have used it almost continually since in several factories, both as a grinding dog and as a lathe turning dog. Although, in common with Mr. Greene's, it carries out the same idea of a gripping cam, it differs in being adjustable, like the ordinary clamp dog.

On paper I developed the proper cam, but never put the theory into practice because at my request Thomas Barter, of the Norton Grinding Co., filed up a cam and attached it to the dog for me without seeing the drawing of the cam I had made. This cam of Mr. Barter's worked so well from the beginning that I have never changed it for one to correspond with my design. Mr. Barter, therefore being a co-inventor with me, went ahead and made some dogs after the plan of the one illustrated by Mr. Greene, for use at the Norton Grinding Co.'s factory. They have been in daily service for a considerable time.

It will be noticed that my dog has a spring against the tail, to compensate for vibration in the driving pin or work. I thought that this spring would be helpful, because the vibration might have a tendency to jar the dog loose, especially in grinding stock in the rough. It will be seen that the swivel pin is placed a trifle to one side of the center line. This arrangement assists the cam in locking the dog to the work positively and yet at the same time enables it to be disengaged easily with a backward pressure of the finger. The dog is put on and removed exactly as a revolver trigger is pulled and almost as easily. Because no wrench is required, it makes dogging very rapid.

The fact that on certain grinding jobs the putting on and taking off of the dog occupy as much time as the grinding operation led me to devise a dog that would be quick acting, and the one illustrated is the result. As a lathe dog it proves very successful on turning jobs, but of course is of no use on pieces that require a change in the direction of the work, as in the reverse return in threading.

While using this dog in the grinding department of the Stevens-Duryea Automobile Co., I was surprised to learn from the assistant superintendent that he had seen a similar grinding dog in Boston a few years ago. This was news to me, as I thought I was the originator of it. In Rochester, N. Y., I also came across a dog almost identical with mine, and I looked it over carefully to see wherein it might be better. Now Mr. Greene brings forward a dog that shows the application of the same principle and that may antedate these others that I know about.



QUICK-ACTING DOG

Joshua Rose, in his work on machine-shop practice, illustrates Shartles' self-tightening dog, in which a pivoted tongue grips the work automatically. The tongue in this case, however, instead of being a cam, has serrated edges, but the principle is very nearly the same. The Shartles dog was patented Apr. 6, 1886, just 30 years ago. ROBERT J. SPENCE.

Worcester, Mass.

Take Warning!

After reading your recent editorials on the great danger to American industries through the adoption of the metric system of weights and measures, those articles impressed me as entirely too subtle if intended to be facetious. If not so intended, they should be supported by much more substantial and convincing reasons than have so far appeared in your paper.

The adoption of the metric system in this country is very much of an open question in the minds of a great many American manufacturers. Men of enlightenment and progressive tendencies are entirely willing to consider the matter in an impartial and judicious way; but assertion that to advocate the adoption of the metric system as Dr. Stratton does constitutes him "the most dangerous enemy of our industries which our country harbors" is a lapse into the burlesque that can hardly be considered appropriate.

What the American manufacturer wants are the facts in the case, not the half-baked conclusions of those who believe that any particular system of weights and measures is an integral part of the Ten Commandments or the Golden Rule, nor assertions of unlimited disaster to come if any change is made in the present system.

If the *American Machinist* is in favor of the metric system, a frank declaration to that effect would be in order. If opposed to the metric system, it should be equally frank. On page 609 in reference to a telegram from the National Association of Manufacturers, signed by George Pope, president, protesting against any change in the present status of the laws of the United States as between systems now in use here, you say, "These actions indicate the attitude of responsible manufacturing and commercial interests of the country toward any attempt to change the present status of our weights and measures." This is obviously funny, whether intended to be or not. It represents the attitude of just exactly those few persons who were consulted about and agreed with that telegram and, as a matter of fact, nobody else. The matter has not been presented to the "responsible manufacturing and commercial interests of the country" for their consideration, and any alleged conclusion as to their "attitude" is manifestly premature and based on incomplete data.

During the last 20 years there has been considerable controversy over the adoption of the metric system in this country; but the discussions that I have heard or have seen in print have too often descended into reasonless denunciation, and this has not been confined to either side of the controversy.

Speaking after an experience of many years with both systems—inch and metric—I am ready to concede that there are good points and bad points about both and that neither is perfection. As to the relative merits of the two systems I would be most willing to express my opinion when the matter is up for discussion by "responsible manufacturing and commercial interests of the country"; but what I wish to point out is that neither my opinion nor the opinion of the "National Association of Manufacturers," by George Pope, president, indicates the attitude of the "responsible manufacturing interests of the country" in any way. HALCOLM ELLIS.

Newark, N. J.

Taper-Shank Drills

I have read with interest the article by Robert J. Spence on page 554. If the author of this article has access to any twist-drill catalog not over ten years old, he can get a far better opinion of the progressiveness of twist-drill manufacturers than he has expressed in the last paragraph of his article. The facts are that the manufacturers of twist drills have gone even farther in putting large-sized taper shanks on small drills than Mr. Spence's recommendations, and they did this a number of years before the article in question was written, without waiting for outside influence, thereby acting on their own experience.

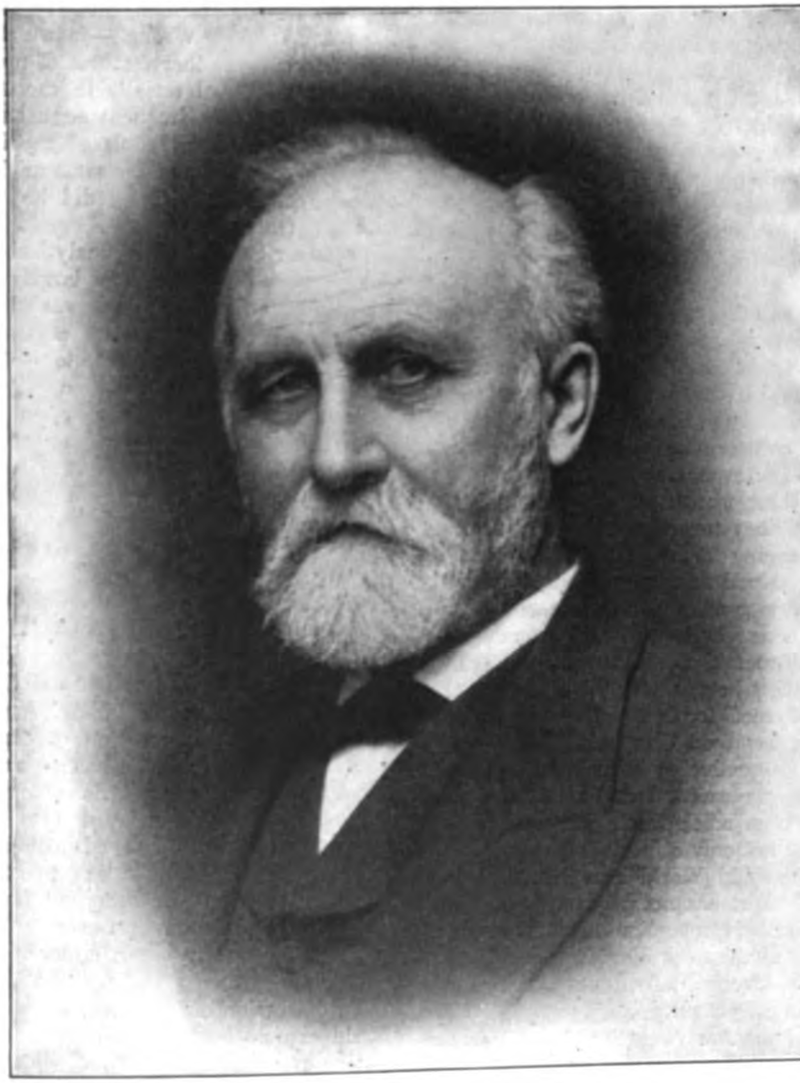
Every catalog of the Cleveland Twist Drill Co. since 1907 shows that taper-shank drills are regularly listed and carried in stock with the No. 2 shank on the $\frac{5}{16}$-in. size—Mr. Spence suggests changing the taper at ½ in. On this same list the No. 2 taper changes to the No. 3 at $\frac{11}{16}$ in. (instead of ¾ in., as recommended by Mr. Spence), and the No. 3 changes to No. 4 at 1⅛ in. Mr. Spence recommends changing at 1 in., but experience has shown that for sizes smaller than 1⅛ in. the No. 3 shank has ample strength. He makes no suggestion with reference to the No. 5 shank, but the drill manufacturers list drills with this shank as small as 1¾ in. in diameter.

It seems only fair to give the devil and the twist-drill manufacturers their due. S. H. COX.

Cleveland, Ohio.

Dr. John Edson Sweet

John Edson Sweet, the venerable dean of American machinery building, engineer, educator and for many years the most endeared figure in the mechanical engineering world, died suddenly at his home in Syracuse, N. Y., on May 8, in his eighty-fourth year. His passing is a great loss tempered only by the realization that to him was granted more years of influence than to the average man in any walk of life. No other engineer of his generation, or of any other generation, has so profoundly modified, directed and advanced the art and practice of machinery building in the United States. Many of those foremost as machinery constructors today came under his teaching, were inspired by his personality through acquaintanceship, or guided by his marvelous mechanical insight through his technical writings.



DR. JOHN EDSON SWEET

John E. Sweet was born at Pompey, Onondaga County, N. Y., Oct. 21, 1832. His father, Horace Sweet, was a farmer at that place where he had settled. The family was descendant of John and Mary Sweet, who came to Salem, Mass., in 1631. Horace was a respectable, though an undistinguished man. His wife, Candace (Avery), however, came of a family that has been somewhat eminent in mechanics. As an inheritance from her, therefore, we may regard Professor Sweet's engineering potentialities. He was one of eight children, six sons and two daughters. One of his brothers, Homer, became a civil engineer and surveyor, while two others, Anson and William, like himself, entered manufacturing at Syracuse.

John's education in the local schools, from the age of 7 to 15, was of an ordinary sort, but during this time, at the age of 12, his constructive resourcefulness manifested itself in the making of a violin. His mechanical disposition was sufficiently marked to bring about his apprenticeship, in 1850, to a carpenter and joiner, John Pinkerton, and with his earnings he purchased the second set of socket or firmer chisels ever made. In the winter of 1850-51 he obtained a position in the office of Elijah T. Hayden, an architect at Syracuse, and during an interval he worked for an artist named Holyoke. The architecture of that date and place was elementary, but young Sweet made the best of it and designed a barn which won a prize offered by the *Rural New Yorker*. This was followed by a series of articles on architecture, which ran for a dozen years. When the war broke out he had charge of building a fine hotel at Selma, Ala., but found it expedient to return North without finishing the job. Building operations being slack, he worked for a while as a pattern maker and draftsman in railroad shops at Syracuse. In 1862 he went to the London exhibition, traveling on the Continent and engaging as draftsman in the international patent office of Hazeltine, Lake & Co. Later he acted as draftsman for the Patent Nut and Bolt Co. of Birmingham, England while this company was building a nail machine of his invention. During the European sojourn he wrote letters of travel to a local paper at home and also contributed articles to Zerah Colburn's London *Engineering*.

Returning to Syracuse in 1864 he became designer and draftsman for Sweet, Barnes & Co., which occupation he suspended long enough to attend the Paris Exposition of 1867 and show a pioneer typesetting machine which he had devised. This is still preserved at Cornell University and is a marvel of ingenuity. He married, in 1870, Miss Caroline Hawthorne, who died in 1887, and two years

later he married Miss Irene Clark, who died about a year ago.

In the period from 1871 to 1873 he did chiefly bridge-building work for Howard Soule, of Syracuse, and at that time wrote articles for *Engineering* on "Mechanical Refinements." He also began work on the first straight-line engine.

Professor Sweet's ownership of that title, which has ever since remained inseparable from him, was acquired through his connection with Sibley College, Cornell University, during the period 1873-79. As professor of practical mechanics, he made a deep and lasting imprint of his personality both on the university and on his students. Under his direction they built some machines embodying features of distinctive originality, among which were the famous Cornell measuring machine, the first American-made Gramme dynamo and the second straight-line engine. The last mentioned was an innovation, combining a balanced valve, shifting eccentric and shaft governor. The engine and other devices were exhibited at the Centennial in Philadelphia.

The measuring machine was the first to be built in this country and was intended to have been the starting point in the manufacture of solid caliper gages of which Professor Sweet was the originator. The manufacture of these gages proved to be a failure owing to the imperfect nature of the only emery wheels then to be had.

Professor Sweet resigned his scholastic work to return to Syracuse and engage in the commercial manufacture of his engine. To this end the Straight Line Engine Co. was formed in 1880, he becoming president and general manager and his brother Anson, treasurer. They rented a building for two or three months at the start and employed six men. Here they turned out about one engine a month in sizes averaging 25 hp. In 1884 a foundry that had been run by a local firm was added to the business. Ten years saw a gratifying development of the enterprise. In 1890 a new building 130 ft. square—one of the first saw-tooth-roof shops—was occupied. Professor Sweet believed that he was the first to employ this weaving-shed type of roof for machine-shop purposes, although the priority has been disputed. There ninety men were employed in producing some fifty engines a year, averaging 80 hp. per unit. Subsequently the plant and production have been much further expanded. His engines have sold well, not only at home but abroad. His close relations with the Old World have therefore been reciprocal ones. His plant has not become large, but it enjoys a reputation out of proportion to its magnitude, because of the quality of the work done in it and because of Professor Sweet's strong individuality, which has permeated his mechanical output.

In the formation of the American Society of Mechanical Engineers, Professor Sweet played a leading part. The idea was discussed in correspondence between him and Jackson Bailey, then editor of the *American Machinist*, as a result of which a call was issued Jan. 18, 1880, over Professor Sweet's signature, and the organization meeting was held Feb. 16, in the office of the journal named. He manifested, however, some hesitancy in promoting the enterprise and an unwillingness to accept its early honors. He consented, nevertheless, to read the first paper and was its third president. Except for his own modesty he would undoubtedly have been its first president.

Professor Sweet never permitted his engineering abilities to grow rusty. He improved his engine from time to time and he designed other devices, such as a traversing machine and a steam separator. His forte lay in the perception and employment of those designs that were artistically simple and mechanically correct. He undoubtedly surpassed all other machine designers in his perceptions of the part in construction which is the outgrowth of perfect fitness, and also in his perception of fundamentally correct principles in construction, as illustrated, for example, by the three-point system of machine support, which is now so common, but which during his early advocacy of it, was smiled at by all as a useless refinement, or worse. Typical of his genius was one of the later among his many literary productions—"Things That Are Usually Wrong"—in which he discussed bearing surfaces and other features of machine design. This was first published serially in the *American Machinist*, to which he was a frequent contributor. Over the door of his engine works he placed the inscription "Visitors Always Welcome," and the same might have been written on his forehead, so freely did he admit others to the confines of his brain.

Professor Sweet had an analytical mind of a very high order, yet he did not depend largely upon formal mathematics in his designing. He was so uniformly correct in his methods and deductions, and these were so simple and direct, that he seemed to be possessed of almost infallible mechanical intuition. His results, however, were in reality due to a clear conception of *all* of the factors of a problem and of the interdependent relations of these factors. This is the characteristic of true analysis, the prime difference between Professor Sweet and others who have been eminent in analytical work being that he employed less conventional expression in conveying his thoughts to others. Nearly all true analysis consists in such a conception of the problem in advance of its mathematical expression. Had Professor Sweet been merely gifted with an intuitive faculty he would have been unable to expound and defend his conclusions with such logical and convincing force.

With his keen perception of that which is right in mechanical principles, he had an artist's appreciation of correctness in details. It is difficult to decide which is the more admirable in his designs, the soundness of the scheme or the skill displayed in its execution.

Many have been unwilling to go as far as Professor Sweet in the right direction, but few of those who lacked the courage to follow him ever succeeded in demonstrating that he was in error, either in his theory or in his practice.

In discussion of questions, mechanical or otherwise, he could express himself with extreme clearness and vigor, yet he ever displayed unusual consideration and patience with the views of others. Few men of his attainment were so appreciative of the work of others, and he seemed quite as interested in the good achievements of another as in his own.

The influence he exerted over men, and the inspiration he imparted to those with whom he came into intimate contact, were, probably, his most important, as well as his most enduring, contributions to mankind.

It was fitting that this man whose most natural instinct was to impart of his abundant knowledge should have

(Continued on page 879)

Editorials

Recommendation vs. Action

The discussion before the House Naval Committee during the hearings on the naval appropriation bill of the question of a general staff for the navy has an industrial interest because of the analogy between the two problems of military preparedness and business preparedness.

The navy must be prepared as to material, of course—that is, ships, guns, ammunition, etc.—and also as to personnel—trained officers in sufficient number; likewise thoroughly drilled sailors. These requirements correspond to plant, organization and working force in the industrial problem. These latter, we know from experience, are of no avail even if they are perfect, unless wielded in accordance with a sound, far-sighted policy, campaigning for business on the one hand and developing internally on the other. So in the navy there must constantly be under way the study of plans of campaign, characteristics of ships, use of the fleet in war, etc., coupled with the detailed preparations necessary to put these plans promptly into effect upon declaration of war. The advisability of getting ready is granted, but the question is how to actually get ready.

At present in our navy there are two groups of officers chiefly occupied with this work the General Board and the Chief of Operations with his staff. These officers investigate, report and recommend to the Secretary of the Navy what should be done; and the Chief of Operations carries out what the Secretary approves. A great many naval officers appear to believe that the work of investigating and planning should be vested in one group or general staff and that this staff should have the power to put its work into action—governed by the appropriations and restrictions made by Congress. But there is much opposition to such a plan, because it would set up military authority free from that of civil authority (the Secretary) and thus would seem to be "militaristic" in tenor.

Just a little reflection will bring up the thought that those officers now busily engaged in investigating and reporting and recommending may get tired and discouraged if the things they recommend are not done, that there is a delay between thought and action, that there is a division of responsibility and that there can be no continuity of policy and strategy. This is because there is so much human nature in the people involved—a consideration that must not be overlooked in any plan where concerted action is necessary.

Now turn around and see how this discussion applies to the industrial problem. There are those who recommend a type of organization such that certain members shall always be reporting and recommending and that others shall be doing. Will those who recommend be as painstaking in study and use as careful judgment as if theirs were to be the responsibility of doing what they recommend? Will those who do, feel the same responsibility and enthusiasm that they would if the plans were theirs? Will there be quicker action if recommending and doing are placed on the same shoulders?

Advance in Dynamic Balance

The latest machine and methods for the dynamic balancing of machine parts are described in an article on page 857 of this issue. It is a reprint of a paper presented at the New Orleans meeting of the American Society of Mechanical Engineers. The discussion that it called out is also printed in this issue on page 861.

During the last five or six years the *American Machinist* has published many articles on dynamic, or running, balance, which taken together have described all the important machines and devices used for this purpose, as well as completely reviewing the underlying principles and describing many of the best-known shop methods. That these principles are none too well understood is, however, shown by the following three quotations that touch upon the action of a dynamically balanced body at different speeds.

John Riddell in his discussion states: "It is my opinion that, in order to give a body a perfect dynamic balance, it is necessary to do this at a speed at least equal to the maximum speed at which it is to be operated in actual service, as it is quite possible to have an apparently perfect dynamic balance at one speed and then find that the balance is imperfect at higher speeds. Whereas, if a body is in perfect balance at its highest speed, it will also prove to be in perfect balance at all lower speeds."

E. J. Loring states positively that dynamic balancing at slow speed is not conclusive: "A slow-speed test is by no means conclusive. A body in dynamic balance at 400 r.p.m. may be dangerously far from balance at 3,000 r.p.m.; when corrected for 400 r.p.m. it is safer than when only statically balanced, but its balance is never fully proved at less than its full speed."

Opposed to these two opinions is the following from the discussion by H. P. Fairfield: "A machine part put in running balance at any speed is certainly in running balance at any other speed, if it is not distorted from its true axial conditions."

The latter opinion is the one commonly held and is the one supported by all theoretical considerations.

Mr. Akimoff's machine differs from others that have been constructed in this important feature: All the others rely for their operation upon indicating unbalance. The vibration or deflection of some parts is used as a means to determine the heavy or light side, as the case may be, of the part that is out of balance and perhaps to give some hint as to the amount of this unbalance as expressed in weight.

The Akimoff machine, on the other hand, relies for its operation upon destroying the vibrations caused by unbalance. After the machine is properly set for a part that is to be put in dynamic balance, the vibration of the work-holding frame is zero or practically zero. Once this condition has been set up, it is possible to determine the plane of the unbalanced centrifugal couple, its sign and also its magnitude.

Tributes to John E. Sweet

We will remember him as the doer of the many things for which the engineering world has honored him so signally and so justly, but the memory which will come to us oftenest and which we will cherish most will be of the kindest, most unselfish, most helpful friend we ever knew. E. J. ARMSTRONG.

Our departed friend was one of the most lovable men I have ever known. Not only was he a finished mechanician, but the human element, which makes life worth living, was strongly marked in his character. What visitor to his workshop in Syracuse will ever forget the inscription cut deep into the stone lintel over the doorway, "Visitors Always Welcome"?

In his address as president of the American Society of Mechanical Engineers, thirty-three years ago, he spoke these memorable words:

> Let us hope that, if the high tide of human progress is sweeping on toward a more useful education, the day may not be far away when he who knows what to do and how to do it will be regarded as the equal of him who only knows what has been done and who did it.

May I repeat the beautiful words of the Poet of the Sierras in his tribute to Peter Cooper:

> Or whether to wander the stars or to rest
> Forever hushed and dumb,
> He has done with a zest; he has done his best;
> Give him the best to come.

If it is to be the gateway to the stars, our friend will find cut in the lintel thereof his own lovely words that he placed over the doorway to his earthly workshop, "Visitors Always Welcome." JOHN A. BRASHEAR.

Professor Sweet was a pioneer in that modern practice which has revolutionized the world by applying logic not to what was taught but to actual fact. He did much to destroy that fetish worship of education founded upon books, which had survived from the Middle Ages, in order that true education founded upon the fundamental laws of the universe might grow. This intellectual freedom, combined with his brilliant mechanical genius and his marvelous gift of expressing profound thought in homely language, put him in the very forefront of engineers and engineering educators, as the honors of all kinds conferred upon him amply show.

But to those blessed by the privilege of intimate association with him these traits pale into insignificance in the light of his personal character.

He never preached and never criticized others, yet by his example and above all by his natural mental attitude inspired others with high ideals. He did not make others do right; he inspired them with the desire not to do wrong. J. E. JOHNSON, JR.

The secret of Professor Sweet's wonderful popularity lay primarily in his unfailing spirit of helpfulness. More than all else he was a teacher. With an exhaustless fund of experience and ideas, he was possessed by a desire to impart them to others. Knowing that he had developed principles that were fundamental and correct, his chief aim in life was to secure their recognition and adoption; in this, repetition had no terrors for him, his patience in explaining and expounding those principles having no end. His feelings in this regard found recent expression when, referring to the honors which had been showered upon him, he said, "I would give them all if people would only use the things that I have proved to be good"; for his chief disappointment in life was the slowness with which his ideas were adopted.

His rise to public esteem was meteoric. He took charge of the Cornell shop—an unknown man; he remained there only about five years, and within that short period his reputation was made. Those were the days of small things, but they were also the days of new things; and little as it showed upon the surface, little, probably, as he realized it, the opportunity for the right man was there.

The esteem in which he was held was made manifest in a manner that was unique. I refer of course to the annual dinner tendered first during the A. S. M. E. meetings and later on the occasion of his succeeding birthdays, when his former students—both of the university and the shop—assembled year after year in numbers that tended to increase rather than diminish.

He always considered himself unworthy of the honors that came to him, for he was an absolute stranger to the spirit of self-seeking and self-aggrandizement. He sought to give, not to acquire, but the bread which he cast upon the waters came back to him. As a man he was unique. We will not look upon his like again. F. A. HALSEY.

A host of memories of him, reaching back nearly forty years, crowd upon me. I seem to see again the little straight-line engine that astonished the engineering world at the Centennial Exhibition in 1876; the workshops established by him at Cornell University about the same date; the Straight-Line Engine Works at Syracuse, with the words "Visitors Always Welcome" carved in the stone arch above the front door, and the many evidences of his genius as a designer and as a mechanic to be seen within; the little Apprentices' School which he established in Syracuse about ten years ago and to which for a few years he devoted a large part of his time. I recall his being one of the leaders in founding the American Society of Mechanical Engineers, and I think of him a quarter of a century later as a founder of the Technology Club of Syracuse, of his being president of both societies, of how he was honored by his old pupils of Cornell (who established the little organization of "Professor Sweet's Boys"), of his vigorous and stimulating writing in the *American Machinist* and elsewhere. I think of his pleasant smile and his cheerful voice, of his optimism and his commonsense.

In August last, while waiting two hours at Syracuse for a train connection, I called him on the telephone to inquire for his health. He replied: "I am eating three meals a day, going to the shop twice a day and am drawing my salary every month. Feel as well as ever I did; come up to the house and see me." I did so and was surprised at his vigor and apparent youthfulness.

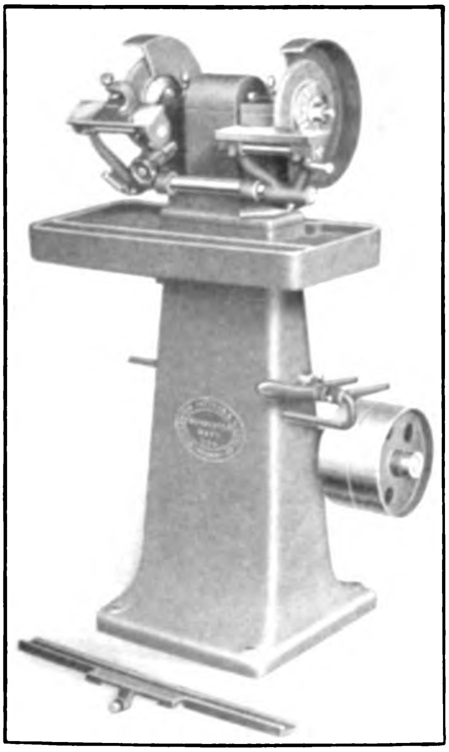
But far beyond these memories of the incidents and the achievements of Professor Sweet's career is the memory of what he was to me as a friend for over thirty years and of the character of the man himself. Friend of mine! He was the friend of thousands. Ranking among his friends the great engineers of the world, who all honored him, among them those who have lately left us—Fritz, Meier, Taylor, Dodge, Leavitt and Woodbury—he was equally the friend of the young college student, the apprentice and the workman. WILLIAM KENT.

Shop Equipment News

Tool Grinder

While primarily designed for pattern-shop work, the machine shown is adapted for machine-shop use in meeting the requirements of general tool grinding. To make it particularly suitable for machine-shop application, plain rests may be furnished for both ends; and the design is such that a buffing wheel can be readily attached by means of a special nut.

The support is first adjusted at the desired distance from the wheel by means of the handle. The tool to be ground is clamped into the tool holder and the proper bevel given by turning the wheel, which tilts the table by means of a worm gear.



TOOL GRINDER

The tool holder is free to slide along the surface of the rest and always holds the tool in exactly the same position. The operator simply moves this holder back and forth until the entire width of the tool has been ground to an accurate edge. When tools with a long edge, like a planer knife, are to be ground, the tool holder shown in the foreground is used upon the table, which is adjustable.

Because the tool is held in the same position during the entire grinding process, the tool holder being in constant contact with the table surface, the edge is kept straight and the grinding uniform.

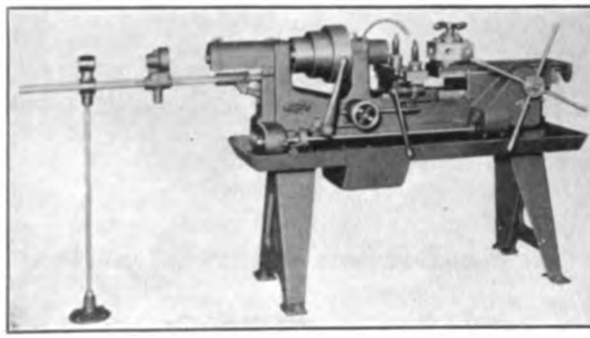
The machine is made either in the solid-pedestal type shown or in bench form by the Worcester Pattern and Model Co., Worcester, Mass.

Hand Screw Machine

In the description of the plain-head hand screw machine made by the Charles Stecher Co., Chicago, Ill., published on page 656, an illustration of another make of hand screw machine was erroneously used.

To clear up any possible misunderstanding the description is herewith repeated with the proper accompanying illustration.

The machine is similar to that shown on page 700, Vol. 43, with the addition of power feed to the turret.



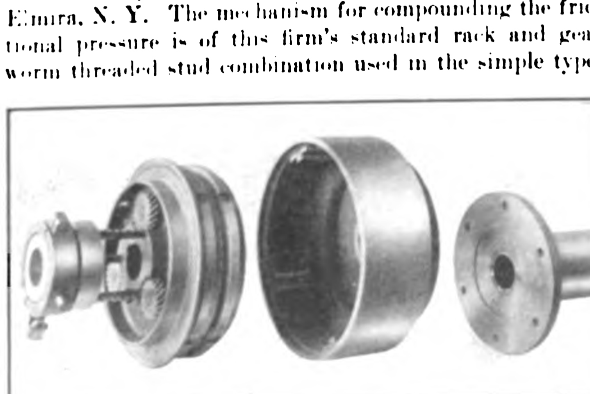
PLAIN-HEAD HAND SCREW MACHINE

Wire-feed capacity, 1⅝-in. round, [illegible]-in. square and 1¼-in. hexagon bars, hole in spindle, 1⅝ in.; swing over bed, 14 in.; diameter of holes in turret, 1¼ in.; length that can be turned, 7 in.; greatest distance from end of spindle to turret, 17 in.; width of belt, 3 in.

The arrangement of the power feed is such that the tools are fed positively the same distance each time. This is accomplished by an arrangement of the friction in the power-feed rod. The friction permits the rod to slip when the tools have reached the positive stop and can be easily seen by the operator, who trips the feed. The gears are entirely inclosed and run in oil.

Double-Disk Clutch

The form of clutch shown is a recent addition to the line made by the Hilliard Clutch and Machinery Co., Elmira, N. Y. The mechanism for compounding the frictional pressure is of this firm's standard rack and gear worm threaded stud combination used in the simple type.



DOUBLE DISK CLUTCH

The compounding pressure ranges from 96 to 1 in the small-size clutches up to 168 to 1 in the largest size; the ratio of travel of the sliding collar, containing the racks, operated by the shifter yoke, has a movement in comparison with the movable friction pressure plate in the same proportion. Only half of the length of the operating racks is required to engage and release the clutches, the remainder being available for automatically taking up wear without stopping to adjust the clutch.

The large-diameter friction disks are lined with asbestos-wire brake linings, four such linings being used. These are riveted to the plates, and the cast-iron plates themselves have hardened tool-steel liners at the point where they drive on the hardened tool-steel keys inserted in the clutch housing, through which the power is transmitted to the pulley mounted on the extended sleeve. The sleeve is separable from the housing, and the sleeve member only is split, for convenience in assembling and rebabbitting without removing the clutch mechanism from the shaft.

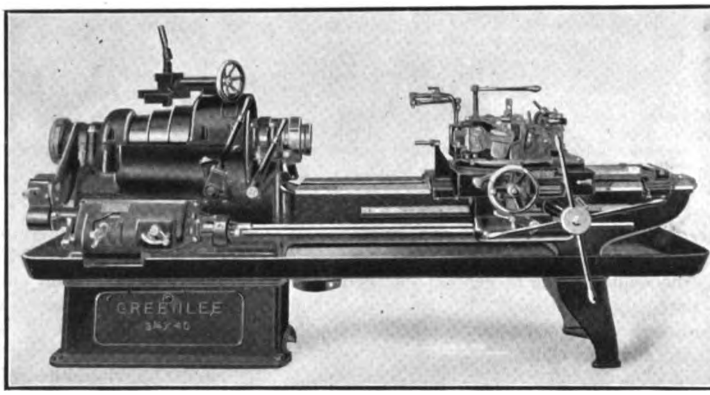
Cone-Driven Turret Lathe

The turret lathe shown is made by the Greenlee Machine Tool Co., Rockford, Ill., and differs in a number of ways from the smaller size made by it. The bed and headstock are a one-piece casting above the pan. It is reinforced under the front-spindle bearing in an unusually strong manner. The bed rests on a three-point bearing. Cone drive is used, and the back-gear shaft is below the spindle, making a compact and well-proportioned head, the outline being completed by the large cast-iron cover inclosing all the parts except the upper half of the cone pulley.

The spindle is of hammered steel, running in babbitted chain-oiling bearings. Large oil reservoirs and glass cups are provided. Spindle thrust is taken through a threaded adjustable clamp collar. The spindle drive for all speeds is through one of two large-diameter wide-faced gears immediately behind the front bearing. These gears mesh with pinions on the auxiliary shaft directly below the spindle, and the pinions are driven by interlocking positive friction clutches keyed to this shaft. At the other end of this shaft are two friction clutches, one driven at high speed direct from the cone and the other at low speed through back gearing from the high-speed gear. Twelve spindle speeds are secured in this way, four from each of the cone steps.

The double friction countershaft gives a reverse drive, so that the speeds are available in either direction. All the clutches are controlled by a single lever, and the connection is such that the positive clutches cannot be shifted while either friction clutch is engaged, nor can the two clutches of either set be thrown in at the same time.

Automatic roller feed is used for handling bar stock. This has only three movable members and is positive in action. The lever opens the chuck and operates the feed. While the illustration shows the crossfeed turret type, the same size of machine is made with a rigid turret.



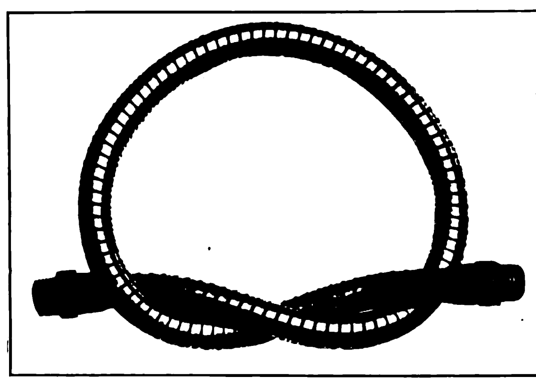
CONE-DRIVEN 3¼x40-IN. TURRET LATHE

Made with cross-slide and rigid turrets. Spindle hole, 3½ in.; maximum swing over ways, 22 in.; over turret, 8 in.; spindle speeds, 12, 16, 21, 28, 38, 50, 66, 88, 118, 157, 211 and 280; feeds, 0.006, 0.009, 0.014, 0.019, 0.035, 0.048, 0.072 and 0.108 in. per revolution; largest step on cone pulley, 15½ in. for a 4-in. belt; weight, 6,600 lb.

A mechanical belt shifter is also provided. It is shown in position on the headstock and over the spindle cover. It operates with a handwheel and gives a rapid and positive belt movement in either direction.

Metallic Flexible Tubing

The use of metallic tubing for conveying lubricant to the cutting tool and for similar shop purposes is growing rapidly and other uses are being found daily.



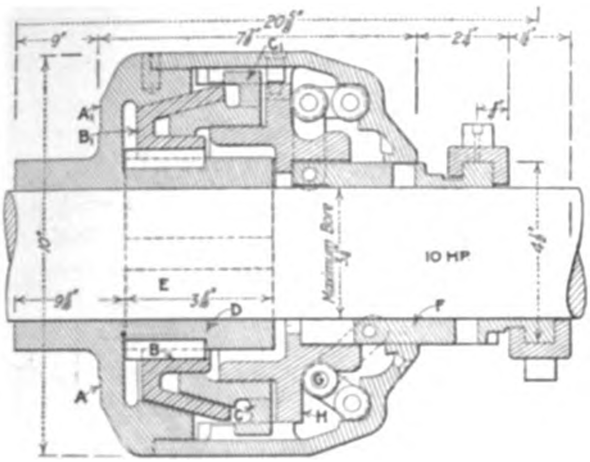
METALLIC FLEXIBLE TUBING

The illustration shows the product of the Worcester Flexible Tubing Co., Worcester, Mass., along this line. This tubing is made to suit varied requirements.

Multi-Cone Clutch

The illustration shows a multi-cone clutch that has recently been developed by the Akron Gear and Engineering Co., Akron, Ohio. The action of the clutch will be readily understood by referring to the illustration. The three cones are shown out of engagement at *A*, *B* and *C* and in engagement at *A1*, *B1* and *C1*.

The driving ring *D* is keyed to the shaft *E*. The driving cone *B* is driven by two feathers in *D*. The driven cones *A* and *C* are brought into contact with *B* when the shifter sleeve *F* is thrown forward. This forces the roll-

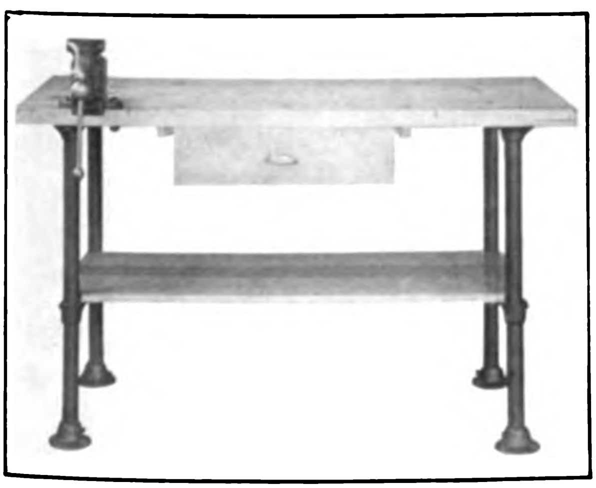


MULTI-CONE CLUTCH

ers *G* outward and moves the adjustment ring *H*, which carries the cone *C* forward into contact with the driving cone *B*. Further movement slides the cone *B* on the driving ring and brings it into contact with the cone *A*.

Mechanics' Bench

The bench shown, provided with vise and drawer, is constructed in such a manner that by loosening the set screws which secure the top to the steel legs the bench can be taken apart for ready removal or substitution.



MECHANICS' BENCH

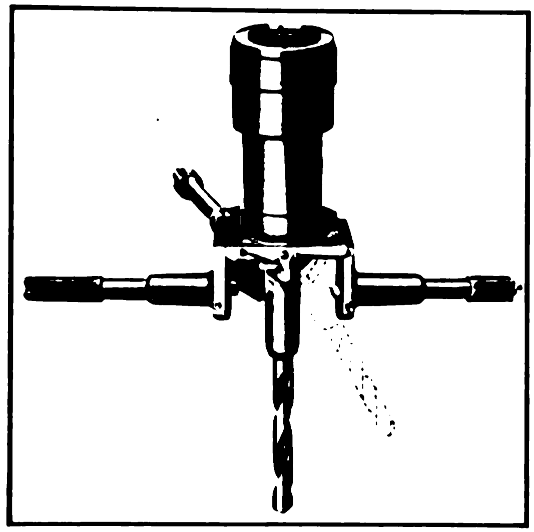
The general construction is apparent, and the design is intended to be especially adapted for tool makers and machinists.

The bench is a recent product of the Motor Engineering Co., East Sixty-first and Curtiss St., Cleveland, Ohio.

Four-Spindle Drill Head

The illustration shows a four-spindle drill head made by the Newman Manufacturing Co., Cincinnati, Ohio. This head is intended for use on the ordinary drill press, the individual spindles of the head being brought into action as required.

The sleeve of the head is secured to the drill-press quill. The spindles of the head are then, as desired, swung into line with the drill-press spindle and locked



FOUR-SPINDLE DRILL HEAD

in place by the latch. Only the spindle in use is rotated by the drill-press spindle, the others remaining inoperative.

A Piston Ring

A piston ring with interlocking joint, illustrated herewith, has recently been placed on the market by the Chalsmith Sales Corporation, 2 Columbus Circle, New York City, and is made in the usual variety of sizes.

A PISTON RING

These rings are made of gray iron cast singly. The skin of the iron is left on the inside, to insure resiliency. The joint is machined to close limits and is practically gas-tight. It can open from $\frac{3}{16}$ to $\frac{1}{4}$ in., according to the size of the ring, before there is passage for the gas.

Balanced Hoist

The balanced hoist here illustrated was made for handling shells or other similar work. In Fig. 1 it is seen used for large bushings. The operator can attach a hook to a piece of work in the lathe or other machine and also a second hook to another piece on the floor or truck. Then with comparatively little exertion he can swing the rough piece to the machine and remove the finished one. The method of operating the clutching jaws is shown in the detailed

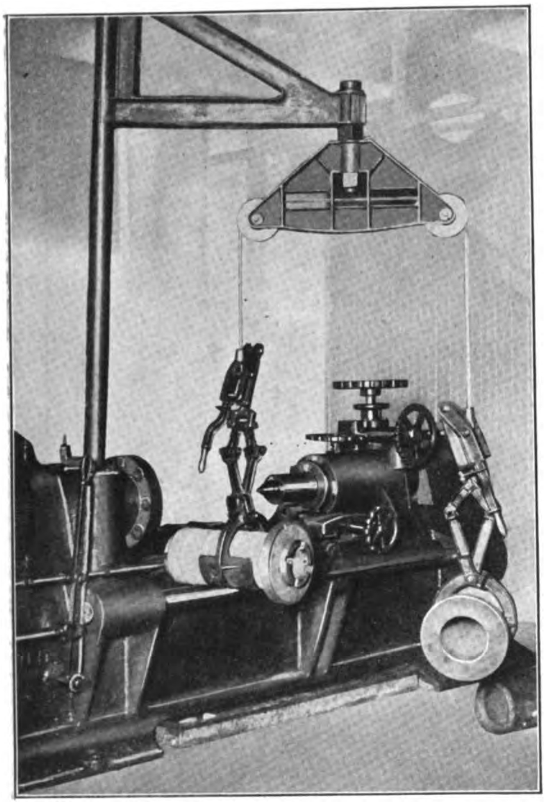


FIG. 1. BALANCED HOIST
Net weight, without upright pipe, 247 lb.

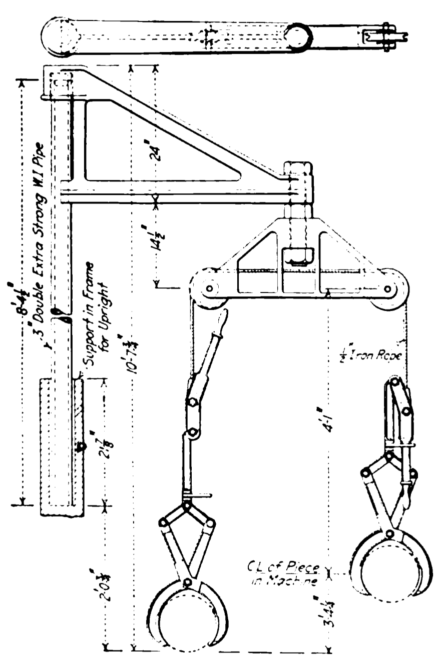

FIG. 2. DETAILS OF BALANCED HOIST

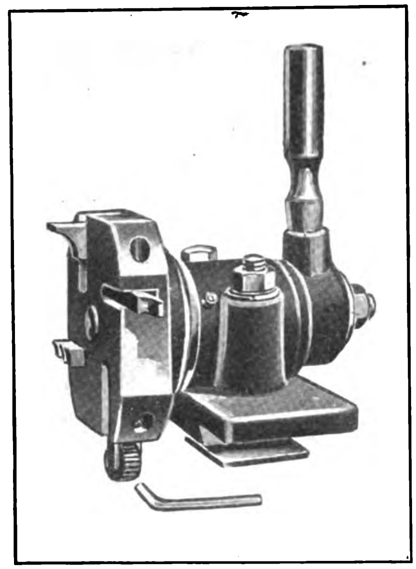
drawing, Fig. 2. All parts are well made and guaranteed to stand up under the rated capacity.

These hoists are made by the Mann Corporation, Chicago, Ill.

Tool-Post Turret

The illustration shows a tool-post turret which is a recent development of the Newman Manufacturing Co.,

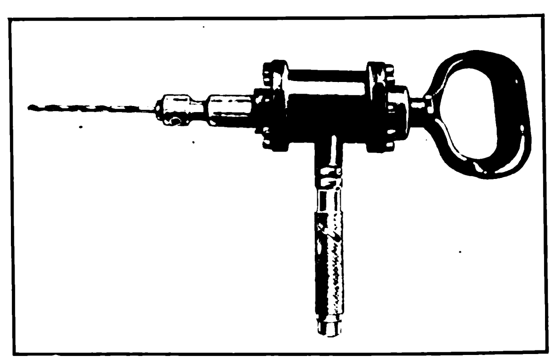


TOOL-POST TURRET

Cincinnati, Ohio. The turret provides stations for four tools. It is mounted direct on the tool slide. The lever to the left operates the locking mechanism.

Pneumatic Telltale Drill

The machine shown, which was designed for drilling telltale holes in locomotive-boiler stay-bolts to meet the Federal law on boilers, is made by the Baird Pneumatic



PNEUMATIC TELLTALE DRILL

Tool Co., Topeka, Kan. It has a speed of 1,500 r.p.m. and weighs less than 4 lb., which enables an operator to handle it for a long time without fatigue. It has but five working parts, including the operating handle.

Dr. John Edson Sweet

(Continued from page 872)

given much of his last years to the Artisan School, which he himself founded in pursuance of a cherished dream of many years.

The most fruitful years of Professor Sweet's life were undoubtedly those spent at Cornell. He went to the university an unknown man and left it after six years of service with a reputation that was more than national. Those were the days of small things in engineering education. The number of students was small, and the department was in a formative state, a condition which perhaps added to his success, as it undoubtedly increased the value of his work from the students' standpoint.

The small number of students made his instruction largely individual and it rendered unnecessary that icy hand of formalism which followed as a necessity upon the great increase in the popularity of engineering education. There never was anything, and there probably never will be anything, quite like that old Sibley shop. It can be compared with nothing but the schools of the ancient Greek philosophers who gathered their students about them without formality, without organization and without system, but with results that from the standpoint of the inspiration received have probably not since been equaled. It is doubtful if such an enthusiastic body of students as Professor Sweet's could be matched then or since, a condition which is perhaps best shown by the fact that most of them spent their spare hours at work in the shop instead of upon the football field, while some passed their vacations in the same manner, partly from an appreciation of the value of what they received, but more from the indefinable charm of the work and of the atmosphere in which it was done.

Few teachers have ever secured the lasting affections of their students as did Professor Sweet. Perhaps the greatest personal gratification that ever came to him was the presentation in December, 1901, of a Jurgensen watch by a number of his former students, meaning by that term graduates from the Cornell shop and from the Straight Line Engine Works. The occasion was managed with such success that he had no inkling of what was coming until the watch was placed in his hands, the result being that his eyes filled and his usual ready speech failed him. Since that occasion the same students, most of them beyond the meridian of life, under the title of "Professor Sweet's Boys," dined with him yearly during the annual meeting of the American Society of Mechanical Engineers in New York—an occasion which was looked forward to with equal eagerness by him and by them.

As an outgrowth of the unstinted esteem of his fellow men Professor Sweet was showered with honors during his later years, always against his protest in his characteristic and unmatchable modest manner. Most notable among these honors was the award of the John Fritz Medal in 1914—the highest award within the joint gift of the four national engineering societies—"for his achievement in machine design and for his pioneer work in applying sound engineering principles to the construction and development of the high-speed steam engine." The degree of Doctor of Engineering was conferred upon him by Syracuse University the same year.

The last day of Dr. Sweet's life was spent in a way that was typically characteristic of him and of all his activities. He went to the shop as usual, about 9:30 o'clock in the morning. A visitor from Texas—a man whom he had never seen, but who knew him through his reputation and writings—came with the design for an inertia governor to control the poppet valves of a steam engine. Dr. Sweet at once went into this problem, spending the greater part of the morning upon it, pointing out that the main pin was in the wrong position and was too small in size, and before luncheon made an appointment with his visitor to meet him again in the afternoon.

Dr. Sweet then went home for luncheon and returned to the shop as usual. About three o'clock he complained of feeling tired and some of his associates persuaded him to go home. This he did, taking care, however, to give detailed instructions as to what should be said to the Texan visitor who was to come again somewhat later in the day.

On reaching home he rested, a physician was called, and he retired. About eight o'clock he was given medicine and five minutes later when the nurse entered his room he was lying in a position of natural sleep with his life's work ended. If he could have preplanned and ordered the events of his last day on earth, it is probable that he would not have wished for the change of a single detail—at least to his friends who remain every event and detail of the day seems singularly fitting and in keeping with the purpose of his whole life.

Chicago Machinery Club Officers

The organization and plans of the Machinery Club of Chicago were announced in last week's isue and further interest in this development now attaches to the election of officers for the initial administration.

The results of the election at the first formal meeting held on May 1 were as follows:

President, Clyde W. Blakeslee, Chicago manager, Abrasive Materials Co.; 1st vice-president, Edward P. Welles, president and general manager, Chas. H. Besly Co.; 2d vice-president, H. A. Stocker, president, the H. A. Stocker Machinery Co.; 3rd vice-president, E. L. Essley, president, E. L. Essley Machinery Co.; treasurer, Arthur L. Beardsley, Chicago manager, Cleveland Twist Drill Co.

The following board of directors was elected: F. L. Peterson, manager, The Hendey Machine Company, Hiram N. Cudworth, Chicago manager, Norton Grinding Company; Herbert E. Nunn, western sales manager, Cleveland Automatic Machine Co.; E. L. Beisel, Chicago manager, Gardner Machine Company, George M. Pearse, western representative, Brown & Sharpe Mfg. Co.; Robt. R. Cuthbertson, manager, Manning, Maxwell & Moore; David F. Noble, creditman, E. L. Essley Machinery Co.

The reported enthusiasm exhibited at the preliminary and first formal meeting of the club confirms the generally accepted belief that the machinery trade in the western section has grown to sufficiently large proportions to well support such a club.

PERSONALS

C. J. Bambach, for several years associated with the Marshall & Huschart Machinery Co., Chicago, Ill., is now vice-president of the recently organized Pierce Machine Tool Co., Chicago, Ill.

R. T. Lane, general sales manager of the Standard Tool Co., Cleveland, Ohio, delivered a technical talk on "Steel, Taps, Drills and Reamers," at Passaic, N. J., on May 15. While intended for the benefit of dealers in that section the talk was open to the general mechanical public and cover both commercial and technical considerations.

Prices--Materials and Supplies

IRON AND STEEL

Pig Iron—Quotations were current as follows at the points and dates indicated:

	May 12, 1916	One Month Ago	One Year Ago
No. 2 Southern Foundry, Birmingham	$15.00	$15.00	$9.50
No. 2 X Northern Foundry, New York	20.50	20.50	14.25
No. 2 Northern Foundry, Chicago	19.00	19.00	13.00
Bessemer, Pittsburgh	21.95	21.95	14.55

Standard Pipe—The following table shows the comparison in discounts, together with the net prices in cents per foot for carload lots f.o.b. mill:

	Black May 12, 1916	Black One Yr. Ago	Galvanized May 12, 1916	Galvanized One Yr. Ago
¾ to 2 in. steel butt welded	70%	81%	50½%	72½%
2½ to 6 in. steel lap welded	68%	80%	48½%	72½%
Diameter, In.				
¾	3.45	2.19	5.69	3.16
1	5.10	3.23	8.42	4.68
1¼	6.90	4.37	11.39	6.33
1½	8.25	5.23	13.61	10.18
2	11.10	7.03	18.32	10.18
2½	18.72	11.70	30.13	16.09
3	24.48	15.30	39.40	21.04
4	34.88	21.80	56.14	29.98
5	47.36	29.60	76.22	40.70
6	61.44	38.40	98.88	52.80

From New York stock the following discounts hold:

	Black	Galvanized
3½ to 6 in. steel lap welded	61%	36%
¾ to 3 in. steel butt welded	64%	42%

Malleable fittings, Class B and C, from New York stock sell at 30 and 5% from list price. Cast iron, standard sizes, 55%.

Bar Iron—Prices are as follows in cents per pound at the places named:

	May 12, 1916	One Month Ago
Pittsburgh, mill	2.60	2.50
Warehouse, New York	3.25	3.15
Warehouse, Cleveland	3.25	3.25
Warehouse, Chicago	3.10	3.10

Cold Drawn Steel Shafting—From warehouse to consumers requiring fair-size lots, the following quotations hold:

	May 12, 1916	One Month Ago
New York	List price plus 20%	List price plus 15%
Cleveland	List price plus 20%	List price plus 20%
Chicago	List price plus 10%	List price

Drill Rod—Discounts from list price in New York are as follows: Standard, 65%; extra, 60%; special, 55%.

Swedish (Norway) Iron—This material per 100 lb. sells as follows f.o.b. places named:

The contract will soon be awarded for the construction of a 2-story, 60x350-ft. reinforced-concrete factory for the Champion Register Co., 6921 Colfax Rd., Cleveland, Ohio.

The Cuyahoga Spring Co., 16606 Waterloo Rd., Cleveland, Ohio, will construct an addition to its plant at Cleveland. Estimated cost, $4,000.

We have been advised that the Ferry Cap and Screw Co. is constructing an addition to its plant at 2147 Scranton Rd., Cleveland, Ohio. Estimated cost, $4,000. Noted May 4.

The contract has been awarded for the construction of a 1-story factory at Lakeside and 51st St., Cleveland, Ohio, for the Forest City Electric Co., Windsor, Ave., manufacturer of electric equipment and automobile parts. Estimated cost, $25,000.

The contract has been awarded for the construction of a 200x500-ft. factory at Coit Rd. and Kirby Ave., Cleveland, Ohio, for the Grant Motor Co., Findlay.

Plans have been prepared for the construction of an addition to the plant of the Kuhlman Car Co., Adams Ave., Cleveland, Ohio.

The Mustee Water Heater Co., 3008 Cedar Co., Cleveland, Ohio, has been granted a permit for the construction of a factory at 3409 Superior Ave., Cleveland. Estimated cost, $10,000. Noted Jan. 27.

The Standard Oil Co. has awarded the contract for the construction of a 60x100-ft. garage at 3041 Broadway, Cleveland, Ohio. Estimated cost, $12,700. Noted May 4.

Work will soon be started on the construction of a 2-story, 60x100-ft. factory at Cleveland, Ohio, for the West Steel Castings Co., 805 East 70th St., Cleveland. Noted Jan. 20.

The New York Central R.R. through its purchasing department in Cleveland, Ohio, is in the market for the following metal-working and wood-working tools for its shops at Coalburg, Ohio: 1 planing machine, one 4-spindle combination horizontal car boring machine, 1 vertical hollow chisel car mortiser with 2 vertical boring attachments, one 42-in. band sawing machine, one 36-in. rip sawing machine, one 2-in. triple head bolt cutting machine, one 2-in. pipe threading machine, one 12-in. power punching machine, one 250-lb. power hammer, one 28-in. vertical drilling machine, one 3x18-in. emery grinding machine and two 10-ton standard electric traveling cranes. G. R. Ingersoll, Cleveland, is Pur. Agt.

The Fyr-Fyter Co., recently incorporated, plans to establish a factory at Dayton, Ohio, for the manufacture of fire extinguishers and kindred lines.

The Galion Iron Works and Manufacturing Co. is constructing additions to its plant at Galion, Ohio.

The Fischer Can Co., recently incorporated, plans to establish a plant at Hamilton, Ohio C R Greer, Secy. Hamilton Chamber of Commerce, is interested.

The Niles Tool Works Co. will construct an addition to its plant at Hamilton, Ohio.

The Standard Car Construction Co., recently incorporated, plans to construct a plant at Hubbard, Ohio Estimated cost, $1,000,000

The Buckeye Foundry Co. is rebuilding its plant at Overpeck, Ohio, which was recently destroyed by fire with a loss of $25,000. Noted May 4.

The Bay View Foundry Co is constructing a 1-story, 60x125-ft. addition to its plant on McDonough St, Sandusky, Ohio. Noted Nov. 4

J E. Galvin, of the Ohio Steel Foundry Co, Lima, Ohio, and others are interested in the organization of a company to construct a steel foundry at Springfield, Ohio.

The Western Conduit Co will construct an addition to its plant at Youngstown, Ohio. Estimated cost, $50,000. L. J. Campbell is Pres.

The Elwood Foundry Co., recently incorporated, will enlarge and equip the plant of the Elwood Iron Works at Elwood, Ind. M. H. Pilkington, Elwood, is in charge.

The Dudlo Manufacturing Co. manufacturer of wire enameling, plans to construct additions to its plant at Ft. Wayne, Ind. George A. Jacobs is Mgr

The United States Steel Corporation is constructing a plant at Gary, Ind. Noted Dec 9

The National Steel Casting Co plans to enlarge and improve its plant at Montpelier, Ind Estimated cost, between $25,000 and $75,000

The Michigan Stamping Co. is constructing a plant on Mack Ave., Detroit, Mich. Noted Mar 9

The contract has been awarded for the construction of a 60x200-ft addition to the plant of the Morton Manufacturing Co., manufacturer of iron working machinery, at Muskegon Heights, Mich

The American Glyso Metal Co will build a 1-story factory at 1625 Rockwell St, Chicago, Ill Estimated cost, $4,000

The Anheuser-Busch Brewing Association, St. Louis, Mo., will construct a 1 story garage at 2609 Jones St, Chicago, Ill Estimated cost, $10,000

The Apex Appliance Co., 3223 West 30th St, Chicago, Ill., manufacturer of washing machines will build a 1 story addition to its factory at Chicago. Estimated cost, $5,500

The Austin Motor Co, 4701 West Maison St, Chicago Ill, will construct a garage at 44 North Saramic Ave, Chicago. Estimated cost, $10,000

The contract has been awarded for the construction of a garage at 5045 Lake Park Ave., Chicago, Ill., for J. A. Carroll

Bids are being received for the construction of a 50x150-ft addition to the plant of the Chicago Bearing Metal Co, 43rd and Western Ave, Chicago, Ill

The Chicago & Northwestern Ry, Chicago, Ill, is in the market for locomotive repair shop equipment, consisting largely of bolt making machinery, forging presses and plate working tools Noted Jan 27

The Cole Manufacturing Co, manufacturer of stoves, 3218 South Western Ave Chicago, Ill, will construct a 2 story machine shop at 2428 Bross Ave, Chicago. Estimated cost, $12,000

W C. Griswold, 3616 Grand Blvd, Chicago Ill manufacturer of steel drawn metal goods, will construct a 2-story factory at Chicago. Estimated cost, $25,000

Bids are being received for the construction of a 1 story, 100x120-ft machine shop for A M Harroun, 5501 Cornell Ave, Chicago, Ill.

The Illinois Central R R, Chicago Ill, is receiving tentative figures for 12 machines for machine shop work A S Baldwin, 135 East 11th Pl, Chicago is Ch Engr

H P Kroencke, 2710 Iowa St, Chicago Ill will construct a 1-story garage at 2611-20 North California Ave, Chicago, Ill. Estimated cost, $10,000.

The Lawrence Manufacturing Co, 9 South Clinton St, Chicago, Ill, manufacturer of metal gasoline lamps, is constructing a factory at Chicago Estimated cost, $75,000.

Matthew Schmidt will construct a 1 story garage at 3720 Southport Ave, Chicago, Ill Estimated cost, $10,000

L. Shon will construct a garage at 825 East 43rd St, Chicago, Ill. Estimated cost, $14,000

The Weller Manufacturing Co, 1840 North Kostner Ave, Chicago, Ill, will construct an addition to its machine shop at Chicago. Estimated cost, $2,000

The Holt Manufacturing Co manufacturer of traction engines, is constructing a 100x180-ft addition to its plant at Peoria, Ill. Noted May 4

The contract has been awarded for the construction of a 2-story, 40x120 ft shop at Grand Rapids, Wis, for the Wood County Cooperage Co Noted Apr 13

C H Lohr will construct a 25x70-ft. machine shop addition to his garage at Hartford, Wis

The Goethal Blow Pipe and Ventilating Co, 627 Prairie St., Milwaukee, Wis, has increased its capital stock, and plans to equip and enlarge its plant at Milwaukee.

The automatic plant of the Harley-Davidson Motor Co., 160 Clinton St, Milwaukee, Wis, is being remodeled.

The contract has been awarded for the construction of a 1-story, 84x100-ft. addition to the plant of the Manufacturers' Foundry Co., 15th and Oklahoma Ave., Milwaukee, Wis.

The Reedsburg Auto Co. will construct a 1-story, 56x115-ft. addition to its plant at Reedsburg, Wis.

The Townsend-Metcalf Automobile Co. is constructing a 3-story addition to its plant at Reedsburg, Wis. Noted Mar. 16.

The Ozaukee Heater Co. will construct a plant at Saukville, Wis., for the manufacture of oil burners and stoves.

F. J. Moeller will construct a 30x60-ft. machine shop at Sturgeon Bay, Wis.

Preliminary plans are being prepared for the construction of an addition to the foundry and finishing shop of the Werra Aluminum Co., Waukesha, Wis.

The John Obenberger Forge Co. plans to construct a factory at West Allis, Wis. John Obenberger, John S. Pease and others are interested.

WEST OF THE MISSISSIPPI

The Ford Motor Co., Detroit, Mich., plans to construct a factory at Des Moines, Iowa. C. L. Herring is Local Agt.

The Central Cornice Works, Sioux City, Iowa, will construct 2 factory buildings at 411 and 469 Water St.

The contract has been awarded for the construction of an addition to the plant of the American Can Co., 747 North Prior Ave., St. Paul, Minn., in the Midway District. Estimated cost, $50,000. Noted Dec. 30 and May 11.

The Tom Thumb Tractor Co., Minneapolis, Minn., plans to take over the plant of the Peteler Cra Co., Como Ave., St. Paul, Minn., and equip it for the manufacture of its specialty.

The Sarnia Fence Co., Ltd., Sarnia, Ont., is building a plant at Stillwater, Minn., which will be branch of United Fence Co. of Port Huron, Mich. T. S. Prendergast is Mgr. Noted Apr. 20.

Plans are being prepared by D. W. Line, Bee Bldg., Omaha, Neb., for a 2-story garage for the Bankers' Realty and Investment Co., Bee Bldg. Estimated cost, $30,000.

J. R. Reardon, Mo., will construct a 2-story, 50x120-ft. garage at 2nd and Joplin St. to be leased by the Overland Motor Car Co.

W E. Zahner, 12 West 10th St., Kansas City, Mo., is building a 1-story, 50x100-ft. brass factory. Estimated cost, $3,000

The contract has been awarded for the construction of a new building for the Korman & Steirly Garage and Machine Shop, Taylor, Tex.

WESTERN STATES

The Port Commission, Seattle, Wash., is in the market for a 35-ton locomotive crane for the South Cove Pier. Estimated cost, $16,000

The Western Scale Co., recently incorporated, plans to construct a plant at Vancouver, Wash. John B. Easter, Vancouver, is interested.

F Gilhuly plans to construct a garage and machine shop at White Bluffs, Wash.

Chanslor & Lyon Co. has awarded the contract for the construction of a 2-story garage at Broadway and Couch St., Portland, Ore. Estimated cost, $20,000.

F. C Knapp, Pres of the Peninsula Lumber Co., and associates plan to construct a shipbuilding plant at Portland, Ore. Estimated cost, $100,000.

The contract has been awarded for the construction of a 5-story reinforced-concrete automobile building at 11th and Hope St, Los Angeles, Calif., for the Harris Newmark Co Estimated cost, $105,000.

The Howard Co. will construct a 1-story machine shop at 1st and Market St, Oakland, Calif. Estimated cost, $5,000.

The Wahtoke Citrus Association will build a packing plant at Reedley, Calif Estimated cost, $10,000.

The Pacific Coast Steel Co., Sacramento, Calif., is in the market for a 75-ton ladle crane.

CANADA

We have been advised that the Canada Stove and Furniture Co Ltd, Montreal, Que, is in the market for cleaning mills, molding machines, sheet steel machinery, polishing machines, etc. Noted May 4

We have been advised that Taylor Bros., Ltd., Carleton Place, Ont, is in the market for a lath, drill, miller, vulcanizer and forge. Noted Apr. 27.

The Goldie & McCulloch Co., Ltd., will construct an addition to its plant at Galt, Ont., for the manufacture of machinery, boilers, etc. Estimated cost, $100,000.

Work will soon be started on the construction of a foundry at Guelph, Ont., for the Guelph Stove Foundry Co.

The Stanley Steel Co. is constructing a steel plant at Hamilton, Ont.

The Harbor Commissioners plan to construct a machine shop on the Don Division near Mill St., Toronto, Ont. Estimated cost, $13,500.

Work will soon be started on the reconstruction of the plant of the Dominion Harvester Co., manufacturer of farm machinery, at Medicine Hat, Alta. The company is in the market for machine tools and other equipment.

GENERAL MANUFACTURING

NEW ENGLAND STATES

The Lunn & Sweet Shoe Co. will construct a 4-story, 82x148-ft. addition to its factory at Auburn, Maine.

McLean & Taylor will build a 3-story, 40x80-ft. cold-storage plant on Elm St., Manchester, N. H.

The Milford Manufacturing Co. plans to construct an addition to its weave shed at Milford, N. H.

The Cherry Valley Woolen Mills awarded the contract for the construction of a 1-story, 62x80-ft. addition to its factory at Cherry Valley, Mass.

The contract has been awarded for the construction of an addition to the plant of the Falulah Paper Co. at Fitchburg, Mass. Noted Mar. 2.

Fire, May 3, damaged the plant of the New England Paper Bottle Co. at Northampton, Mass. Loss, $15,000.

The Glencairn Manufacturing Co., manufacturer of silk fabric, is constructing a 1-story, 80x90-ft. addition to its plant at Pawtucket, R. I.

MIDDLE ATLANTIC STATES

The Globe Woven Belting Co., 1396 Clinton St., Buffalo, N. Y., will be in the market for about 50 looms for its proposed new addition. Estimated cost, $10,000. M. Beecher is Vice-Pres. Noted May 4.

Plans being prepared by William Higginson, Arch., 21 Park Row, New York, N. Y. (Borough of Manhattan), for a 6-story, 100x125-ft. braid dyeing factory for R. H. Comey Co., 78 18th St., New York, N. Y. (Borough of Brooklyn). Estiated cost, $75,000.

The Tempest Knitting Co., Perry, N. Y., is building a new 3-story factory in Tempest St.

Scott & Bowne, Bloomfield, N. J., manufacturer of cod liver oil and chemical specialties, will build a reinforced-concrete addition to its plant on Orange St.

The Victor Talking Machine Co. has awarded the contract for a cabinet plant at Camden, N. J. Estimated cost, $500,000.

The Butler Chemical Co., Butler, N. J., plans to construct a new plant at East Bloomingdale, N. J.

A plant will be constructed at Elizabeth, N. J., by the United Chemical Co., New York, N. Y.

The Pennsylvania Shipbuilding Co., 828 Land Title Bldg., Philadelphia, Penn., is constructing a shipbuilding plant at Gloucester, N. J., and is taking bids for equipment. George S. Hoell, Secy. and Treas.

The contract has been awarded for the construction of an addition to the leather factory of Berkowitz, Goldsith & Spiegel, Garden St., Newark, N. J. Estimated cost, $25,000. Noted Apr. 6 and 27.

Fire recently destroyed a section of the plant of the Consolidated Color and Chemical Co., Brown St., Newark, N. J. Loss, $100,000.

The Empire Leather Co., Newark, N. J., will enlarge and improve its plant on Southh 10th St.

The contract has been awarded for the construction of a plant on Chestnut St., Newark, N. J., for the Hanovia Chemical Co. Estimated cost, $25,000.

The Keystone Reduction Co., New York, N. Y., will build a new plant for the manufacture of acids on Ave. P, Newark, N. J. Estimated cost, $100,000.

The contract has been awarded for 2 additions to the plant of Marden, Orth & Hastings, Newark Meadows, Newark, N. J., manufacturer of oils and acids. Estimated cost, $75,000. Noted Jan. 27 and Apr. 27.

The New Toy Manufacturing Co., Newark, N. J., will build a 1-story addition to its plant on Central Ave.

Thomas Preston, Newark, N. J., manufacturer of leather, will construct a new 2-story factory on Ferdon St.

The Seaboard Chemical Co., Newark, N. J., will construct a 4-story building at the foot of Blanchard St. Estimated cost, $40,000.

The Thermoid Rubber Co., Trenton, N. J., manufacturer of auto tires, etc., has awarded the contract for a 2-story addition to its plant.

The Sun Shipbuilding Co., Chester, Penn., and Finance Bldg., Philadelphia, Penn., is building a 2-story, 55x640-ft. plant at Chester, Penn., with 6 shipways and is taking bids on equipment. Estimated cost, $3,000,000.

The Belmont Packing and Rubber Co., Philadelphia, Penn., will construct a 2-story factory at Sepviva and Butler St. C. P. Berger, Arch.

Plans are being prepared for a shoe factory at Richland, Penn., for the Curtis & Jones Co., 702 West 8th St., Reading, Penn. Estimated cost, $20,000.

We have been informed that the Rich Woolen Mills, Woolrich, Penn., will be in the market for looms, etc., for its proposed new addition. Noted May 4.

The Linde Air Products Co., 30 East 42nd St., New York, N. Y., manufacturer of oxygen, etc., plans to construct a plant at Baltimore, Md.

SOUTHERN STATES

The American Agricultural Chemical Co., Boston, Mass., has awarded the contract for the construction of a plant at Alexandria, Va., for the manufacture of guano.

The cotton compress of the Sheffield Cotton Co., Sheffield, Ala., recently destroyed by fire with a loss of $125,000, will be rebuilt. Noted May 4.

MIDDLE WEST

Plans have been prepared for the construction of a factory for the National Artificial Silk Co., 735 Central Ave., Cleveland, Ohio. Estimated cost, $300,000.

The American Lace Co. contemplates constructing an addition to its plant at Slyria, Ohio. Estimated cost, $10,000.

The Central Ohio Paper Co., 124 Ontario St., Toledo, Ohio, is constructing a factory at Toledo. Estimated cost, $50,000. Noted Feb. 3.

Work will soon be started on the construction of a 7-story, 120x130-ft. factory at Grand Rapids, Mich., for the Globe Knitting Works. Noted Apr. 27 and May 11.

Fire, May 4, damaged the plant of the Acme Asbestos Co. at Kinzie and Ada St., Chicago, Ill. Loss, $5,000.

The L. A. Harsha Manufacturing Co., 2010 Carroll Ave., Chicago, Ill., has awarded the contract for the construction of a 4-story, 60x75-ft. factory at Kinzie and Lincoln St., Chicago, for the manufacture of moldings and frames.

The Western Packing Co., 3854 South Morgan St., Chicago, Ill., will construct a packing plant at 38th and Morgan Ave., Chicago. Estimated cost, $400,000. John Haltzel is Vice-Pres.

The H. M. T. Chemical Co., Merchants Laslede Bldg., St. Louis, Mo., will equip a plant at East St. Louis, Ill., for the manufacture of coal tar dyes. Estimated cost, $50,000.

The contract has been awarded for the construction of a factory at Eau Claire, Wis., for the Gillette Safety Tire Co.

The Bain Wagon Co. is constructing a 3-story addition to its plant at Kenosha, Wis.

The contract has been awarded for the construction of an addition to the plant of the Morgan Co., manufacturer of sashes, doors and blinds, at 6th and Oregon St., Oshkosh, Wis.

WEST OF THE MISSISSIPPI

B. L. Fields, Temple, Minn., plans to install a canning factory.

The Fredonia Realty Co., St. Louis, Mo., has awarded the contract for the construction of a 2-story building to be occupied by the Goodyear Tire and Rubber Co., 1909 Locust St., St. Louis, as a shop and sales building.

The Standard Corrugated Box Co., St. Louis, Mo., recently incorporated with $15,000 capital stock, plans to equip a plant for the manufacture of paper and fiber boxes. George C. Huth, Jr., is interested.

A cotton gin will be established by the Merchants and Farmers' Gin Co., McGhee, Ark. About $12,500 will be expended on machinery. George B. Ewing is Pres.

Anderson, Clayton & Co., Houston, Tex., has awarded the contract for the construction of a cotton concentration plant. Estimated cost, $83,000.

WESTERN STATES

Work will soon be started on the construction of an addition to the factory at Camas, Wash., of the Crown-Willamette Pulp and Paper Co., Portland, Ore.

The Kanite Explosive Co., Seattle, Wash., plans to build a plant near Renton, Wash. Joseph Bjorn is Pres.

The National Canning Co. will construct a cannery at Seattle, Wash. Estimated cost, $50,000.

The Quinault Salmon Packing Co., recently incorporated, plans to construct a cannery at Tacoma, Wash.

The Oregon Packing Co. is constructing 2 additions to its plant at Vancouver, Wash.

E. J. Crandall, Los Angeles, Calif., and T. F. Burke, Secy. of the Bakersfield Board of Trade, Bakersfield, Calif., are back of a movement to construct a sugar factory at Bakersfield.

The Pacific Fruit Express Co. plans to construct an icing plant near Pacific Electric tracks at Colton, Calif. Estimated cost, $35,000. L. E. Cartmill is Supt.

The United States Rubber Co., Los Angeles, Calif., plans to equip a 3-story factory at 921 South Los Angeles St., Los Angeles. J. B. Magee is Local Mgr.

The Oakland Textile Manufacturing Co., manufacturer of woolen goods, plans to construct a 2-story plant at Oakland, Calif. Estimated cost, $50,000.

The V. K. Sturgis Co. has awarded the contract for the construction of a 1-story automobile tire factory on Foothill Blvd., Oakland, Calif. Estimated cost, $12,795.

The San Diego Sugar Co. plans to construct a factory at San Diego, Calif. Estimated cost, $200,000. H. S. Hadsall is Dir.

CANADA

The Fleishhacker & Johnson interests of California plan to construct a paper mill as an addition to the pulp mill at Ocean Falls, B. C. Estimated cost, $2,500,000. Crown Willamette Paper Co., L. Bloch, Vice-Pres. and Gen. Mgr., San Francisco, Calif., interested.

Machining Valve Sleeves for Knight Motors

By Fred H. Colvin

SYNOPSIS—The good mechanic does not attempt the impossible. Knowing that a thin sleeve will spring if left to itself and that it will be held true when in use, the obvious solution is to hold it to its proper shape while it is being machined. This requirement involves very accurate roughing or first cuts, in order to have the sleeves fit properly in the fixtures that are to hold them.

The making of the sleeves, or sleeve valves, of the Knight engine is an interesting machine-shop proposition, and the way in which it is handled by the Moline Automobile Co., East Moline, Ill., well illustrates some of the mechanical problems involved and the ingenious and workmanlike way in which they are solved. These sleeves are approximately $4\frac{1}{2}$ in. in diameter and 8 to 10 in. long; and when it is considered that the thickness is only $\frac{1}{8}$ in. and $\frac{3}{32}$ in. respectively, the perplexing features of the problem become more apparent. The difficulty of securing and maintaining cylindrical sleeves of such a thickness has developed the use of a number of interesting methods and fixtures that may have application in other fields.

Fig. 1 shows sleeves in some of the various stages of development from the rough casting to the finished product. The one at the right, however, is a short outside sleeve *F*, which happened to be the only one available in the finished condition. Beginning with the rough casting *A* at the left, the end of the chucking piece is disk-ground on the bottom to make a flat surface and is ground square with reference to the center of the lugs or ears, to which the driving rod connects. The sleeve is then rough-turned on the outside, rough-bored, the end faced off and chamfered inside and out, finished on the inside of the bottom end by a tool coming through the lathe spindle, and the undercut *G* is turned by the cross-slide—all on a Potter & Johnston semiautomatic.

The third operation is to hold the rough-turned sleeve *A* in its draw-in collet *B*, Fig. 2, also on a Potter & Johnston lathe, while the holding ring *C* is cut off, the bottom faced off and chamfered and the first reaming operation performed. In order to hold the sleeve successfully in a draw-in collet it is necessary that it be of practically uniform diameter, so that the so-called rough-turning is more properly a first turning within close tolerances instead of a rough-turning in the usual sense. The sleeve must fit the draw-in collet quite accurately or the desired results will not be obtained. The two pins on *B* are to relieve the driving stress on the chuck.

There is a single-point boring tool in front of the reamer, which leaves 0.007 in. for reaming, while the

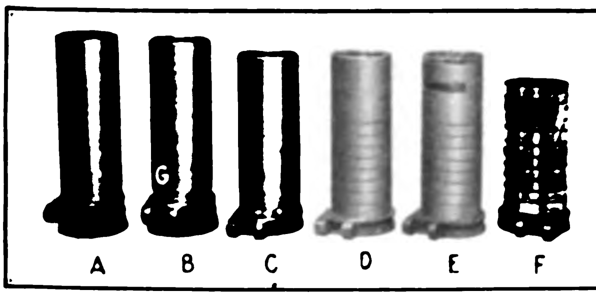

FIG. 1. PARTIAL SEQUENCE OF OPERATIONS

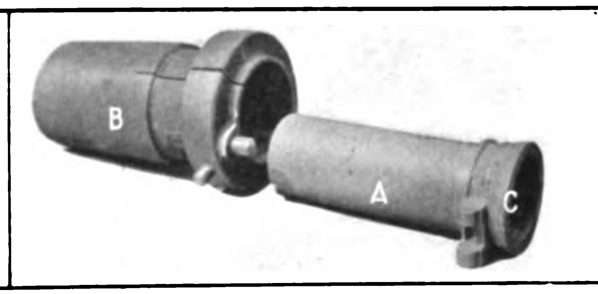

FIG. 2. CHUCK FOR FINISH BORING

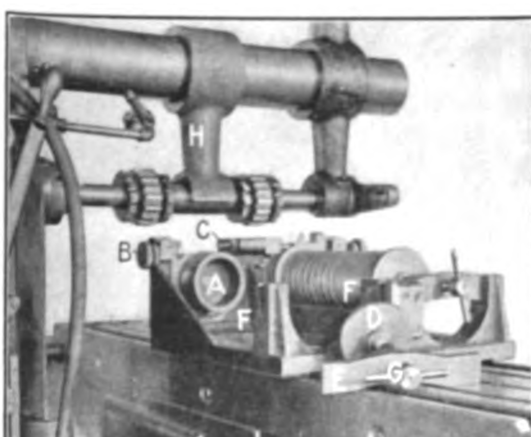

FIG. 3. MILLING DRIVING EARS OF SLEEVE

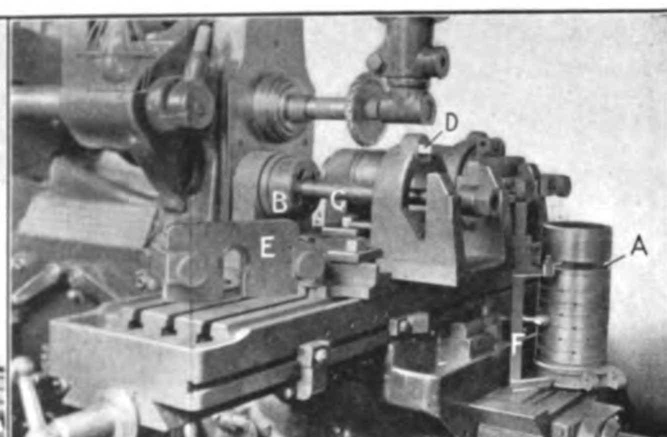

FIG. 4. MILLING SLEEVE PORTS

reamer leaves from 0.018 to 0.02 in. for the final reaming. The second turning is done on a Fay lathe, which is kept solely for finish-turning of the sleeve and the head. In this way extreme accuracy can be maintained. This lathe also turns the oil grooves in the sleeve, the work being clamped on a mandrel that centers and clamps the sleeve without tending to distort it.

The driving lugs are next milled with a double gang of form cutters, Fig. 3. Two sleeves are milled at one effectually prevents spring and enables a heavy cut to be taken without chatter.

The intake ports are next milled, as shown in Fig. 4, this fixture being designed along somewhat similar lines to the one in Fig. 3, but modified to suit the differing conditions. The illustration shows one sleeve in place under the milling cutter and the other part of the fixture empty, so that its operation will be perfectly clear. The milling cutter is set over the sleeve at the proper joint,

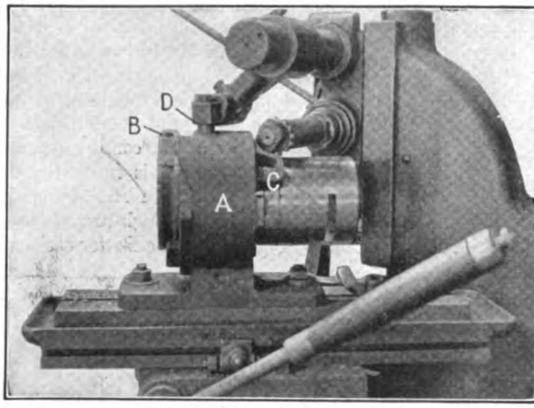

FIG. 5. MILLING SPIRAL OIL GROOVES

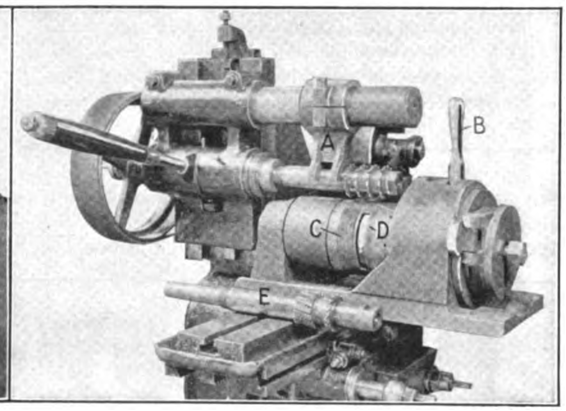

FIG. 6. MILLING OIL GROOVES

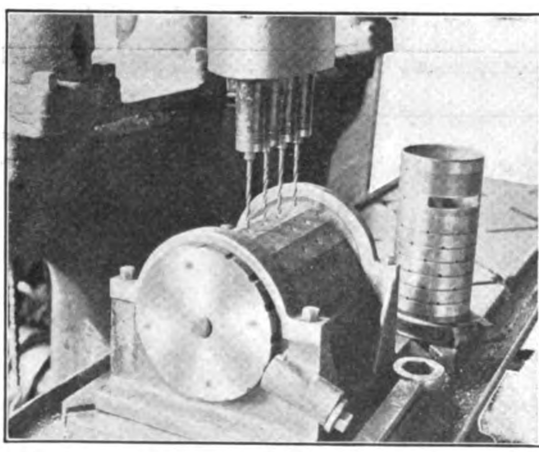

FIG. 7. DRILLING OIL HOLES IN SLEEVE

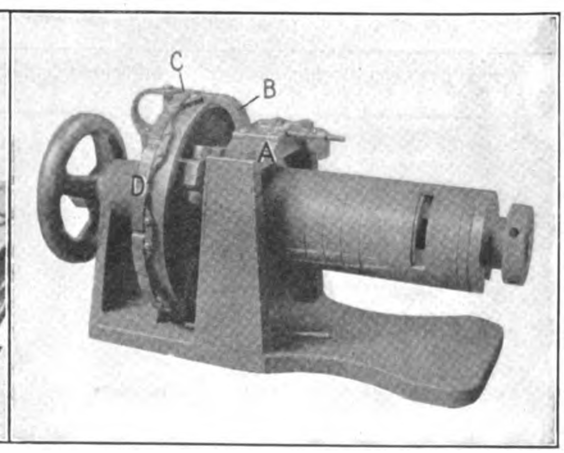

FIG. 8. OFFSET DRILLING JIGS

setting, as can be seen, the near side of the fixture being left empty to show its construction and the way in which the sleeve is clamped. The base of the sleeve fits over the projection *A*, which locates this end, while the thumb-screw *B* adjusts the lug against the hardened stop *C* so that the sleeve can be exactly located at each setting. The other end is centered and supported by the clamp *D*. The crossbar *E* drops into the slot *F*, and the jackscrew *G* tightens to hold it firmly in place. This arrangement gives a fixture that is easily operated, so that the handling time is about as low as can be secured.

It will also be noticed that precautions are taken to prevent the upward spring of the milling-cutter arbor by the introduction of the arm *H* with a half-bearing placed between the two gangs of cutters. This feature and after adjustment to the correct depth it cuts the port to the desired size, as at *A*.

The end of the sleeve is supported on the plug *B*, the sleeve being slid over the bolt *C* so that the driving lug will locate properly against each side of the stop *D*. The plate *E*, carrying the two knurled-head screws shown, slips over the rod *C* and forces the sleeve firmly in place while the port is being milled.

The location of this port is tested by the vernier height gage *F*, seen in position on a finished sleeve. The other port is milled in a similar manner, which it is unnecessary to illustrate.

The spiral oil grooves *F*, Fig. 1, are next milled by the fixture illustrated in place on the hand miller in Fig. 5. The cylindrical base *A* carries an inner sleeve in

which the sleeve valve fits. This valve is located by the lugs *B*, and the spiral is produced by the slot shown in the inner sleeve at *C*. As the table is moved back and forth by the hand lever in front, the stationary guide pin *D* acts in the spiral slot and turns the sleeve as it passes under the milling cutter.

The short oil grooves on the side of the valve are milled in a somewhat similar fixture, Fig. 6. The miller spindle carries a gang of cutters, supported against upward thrust by the overarm bearing *A*. The sleeve is located by the lugs, as before, and the short oil grooves are milled by moving the sleeve back and forth under the cutters by the handle *B*, the amount of movement being determined by the length of the slot. There is a second slot, as can be seen, to which the handle is transferred so as to secure a slightly different indexing, if it can be so called.

There are also fine serrations on each side of the port opening, as at *C* and *D*. They are milled in a similar way by the gang of cutters *E* on the miller table.

Oil holes are next drilled through the sleeve by the four spindle head and the fixture illustrated in Fig. 7. This is an indexing fixture that can drill 16 series of four holes each, as can be seen.

Fig. 8 shows the manner in which each successive row of holes is offset. This method prevents errors on the part of the operator by blanking first one drill bushing and then the other by means of a sliding plate. The sleeve is located by its lug in the usual way, the drill bushings being carried in the plate *A*. One of these bushings is covered by the slide *B*, according to its position as controlled by the cams *C*, each alternate position on the index being covered by one of these cams. This procedure makes it impossible for the operator to enter the drill in the wrong bushing, and it is a very simple method which may have other applications.

The next operation is drilling the ears of the sleeve for the bearing pin and is accomplished in the fixture illustrated in Fig. 9. Here the block *A* locates the sleeve and also supports it against the drilling stress. The hole is located both with reference to the sleeve diameter and the location of the port *B*. This port fits over the block *C*, while the ears go over the block *A* and the swinging portion of the jig *D* centers and holds it in place while being drilled. For quick handling, the clamping is done by dropping the enlarged head bolt *E* over a suitable slot in the upright side of the drilling jig, the final clamping being done by the nut at the other end. The reamer and its bushing are shown in place in the fixture, but the drill and its bushing can be seen under the swinging portion *D* of the jig.

All these operations have been performed on the sleeve in its rough condition, both as to the outside and inside finish. Recalling that they have been done in sleeves or on locating plugs or mandrels, the necessity for maintaining accuracy in the roughing, or more properly the first, operations will be seen.

Before either the inside or the outside is finished, the sleeves are carefully annealed in large furnaces. The sleeves are heated up slowly to about 500 deg. F. and then allowed to cool off in the furnace, in which they are usually left overnight, so that all internal stresses are removed before the sleeves are taken out of the furnace.

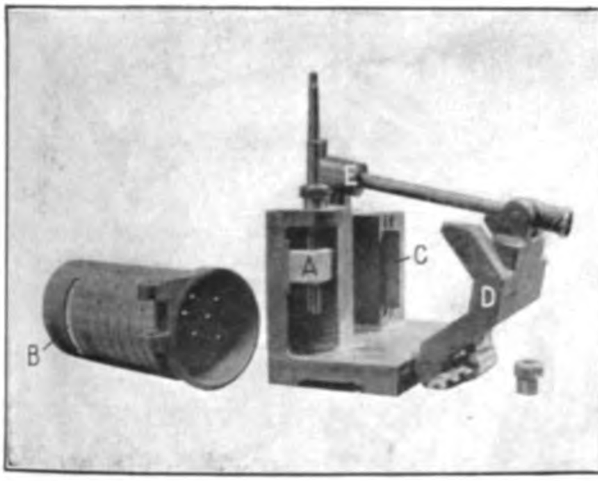

FIG. 9. DRILLING DRIVING LUGS ON SLEEVE

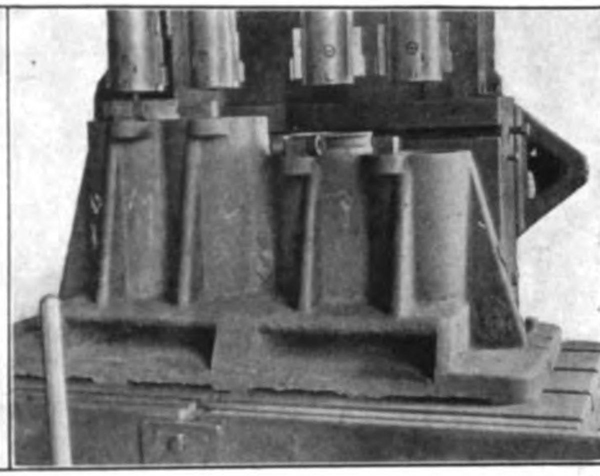

FIG. 10. BORING BOTH LENGTHS OF SLEEVES

Finish-boring is the next operation, and it is done in the fixture seen in Fig. 10. This fixture handles two of the long sleeves and two of the shorter ones, the lugs being used to prevent the sleeve from turning under the action of the boring cutter. The cutters are of the floating type, the operation being performed in a four-spindle Moline vertical drilling machine. The fixtures are quite heavy and are accurately bored to size, so as to hold the sleeve firmly at all points while it is being bored. The walls being so very thin makes it impossible to prevent the sleeve from going out of round during various operations as well as in the annealing process. These heavy fixtures force the sleeve back into a cylindrical position, so that it is bored with reference to its outside surface.

The pieces are next finished by grinding on the outside, being slipped over a mandrel of the proper size and held concentric with the finish bore while they are ground. Extreme care is taken to maintain finish sizes so as to hold the sleeve concentrically during both the finish-boring and the finish-grinding of the outside.

It has been found that when the boring fixture or the grinding mandrel wears slightly below the size, it is an easy matter to increase either dimension by changing the surface with a thin layer of blue vitriol, or sulphate of copper, such as is used for laying out work. Although this treatment adds a seemingly inappreciable amount, it is often found sufficient to restore the fit desired.

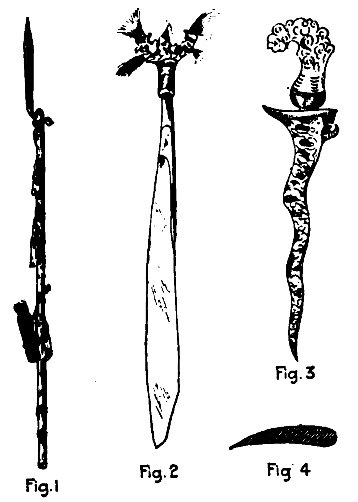
Bornean Head-Hunters as Expert Mechanics

By Jan Spaander

Hardly credible feats of mechanical skill are performed in Central Borneo (Dutch East Indies) by the head-hunters. Any man, with the best machinery at hand, may regard himself an accomplished machinist if he can drill a 1/4-in. hole 7 ft. long, straight, highly polished and without a flaw in the boring. The writer saw that feat performed time and again by Bornean head-hunters (Dyaks), and without machinery. To them war is no necessity, and murder is a fine art for which superfine tools are required. A grandfather will spend many hours of a lifetime to provide his grandson with a fighting outfit—a *chris*, a *parang-ilang* (sword), a shield and a blow-pipe with bayonet.



FIGS. 1 TO 4. BORNEAN WEAPONS

The head-hunter has to start at the very beginning. In a turbid brook he will fish for warty, root-like pieces of carbonate of iron, which shows a silvery fracture. A heap of the ore mixed with charcoal from a burned-down forest is covered with clay to regulate the air for the combustion while the iron is roasting. From an economic point of view the results obtained are very poor. This process leaves the Dyak a heap of slacks and a small piece of really fine malleable iron. Out of this he makes his weapons.

The *chris*, Fig. 3, a Javanese novelty, is a crooked piece of steel, which has to be buried in wet earth to rust the edges sharp. The more corrosive parts of the metal deteriorate first, and the finished article shows beautiful waves all over, their steel, notwithstanding all the hammering, not being as homogeneous as ours. The bayonet on the blow-pipe, Fig. 1, resembles the latest European models. The *parang-ilang*, Fig. 2, does not resemble any white man's work. It is superior to our sword in every point, but it misses the wrist protector. The blade widens toward the end, and this produces the killing swing. The thick back gives it the necessary weight. The blade is convex on one side and slightly concave on the other, as shown in Fig. 4. Lengthwise the blade has a slight twist. All these little points enable the skillful fighter to sever a head at a single blow.

The mechanical masterpiece, however, is the boring of the blow-pipe, which is used to dispatch small poisoned arrows with deadly accuracy. For this the Dyak chooses a very tough log of wood about 6 to 7 ft. long and fastens it rigidly in vertical position to a scaffolding as in Fig. 5, leaving him ample room to work underneath. His only tool is a long, thin iron rod, chisel shaped at the end.

This rod he throws up with measured stroke and clock-like precision, striking the center of the vertical log. Gravity is the guide for the direction of the boring; and

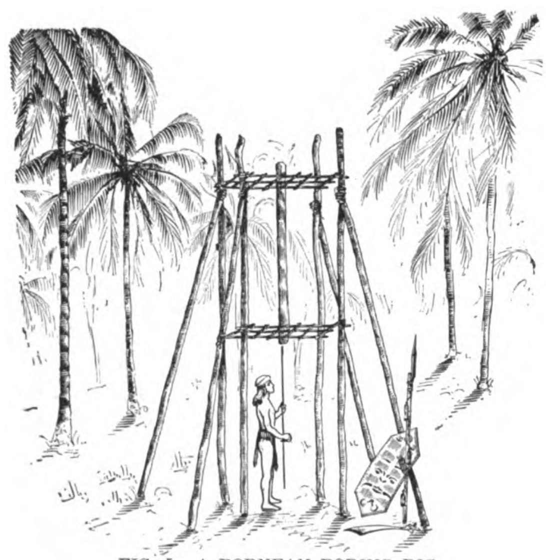


FIG. 5. A BORNEAN BORING RIG

as the Dyak has no instruments to insure a perfect vertical to the raw material, he simply takes a log much thicker than the finished blow-pipe he wishes to make.

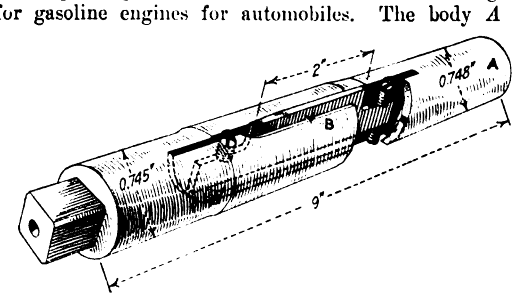
When through, he takes a thin rattan, which grows abundantly in the forest. He works this up and down in the blow-pipe till a high polish is obtained. The smaller the bore the more effective the weapon. There are blow-pipes over 7 ft. long with a 5-mm. bore.

It is unnecessary to point out that the head-hunter mechanic is no pieceworker and that time is no object to him.

Reamer for Piston-Pin Hole

By Nathan B. Hord

The piston-pin reamer here illustrated is a tool designed for gasoline engines for automobiles. The body *A* is a piece of cold-rolled steel with a piece of hacksaw blade *B* for the reamer cutter made to the given dimensions. After assembling the reamer, the body is ground.



REAMER FOR PISTON PIN

Special Machines for Drilling and Milling Fuse Parts

SPECIAL CORRESPONDENCE

SYNOPSIS—The many screw holes, powder passages and wrench flats in the parts of either time or detonating fuses have been responsible for the development of some unusual machines for this work. A group of these built by the Langelier Manufacturing Co., Providence, R. I., for both drilling and milling are shown herewith.

The machine shown in Fig. 1 drills simultaneously the four crossholes in the neck of the domed nut, Fig. 3. This nut is of brass; the drills are No. 36 (0.1065 in.) and are run at 2,500 r.p.m. The output is 8 pieces per minute, or 480 per hour. This machine was also used, with slight alterations to the chucking parts, for drilling the four No. 37 (0.104 in.) holes located at quarters in the beveled face of the fuse body, Fig. 11. The output in this case is 600 per hour.

The pieces are located by a jig having a drilling guide bushing for each of the four spindles. It is adjustable on its axis and is provided with a compression spring and stop arrangement that automatically pushes the jig ahead from between the drills to a position where the pieces can be put in or taken out by the operator. A pressure spindle actuated by a foot pedal holds the pieces in the jig during the drilling. The operator places a piece on the end of the spindle and presses the foot pedal down till the piece stops at its drilling position, where it is held while the holes are drilled.

All the drill spindles are fed by the crank hand lever that transmits motion with a segment gear to a wheel that carries a feed cam for each spindle. These cams engage with rolls mounted on the ends of feed yokes, the outer ends of which have clamp connection to the sleeves on the outer ends of the drilling spindles. The wheel has adjustable stops for drilling the depth required. The clamp connection permits a longitudinal adjustment to the spindles for the shortening of the drills by grinding.

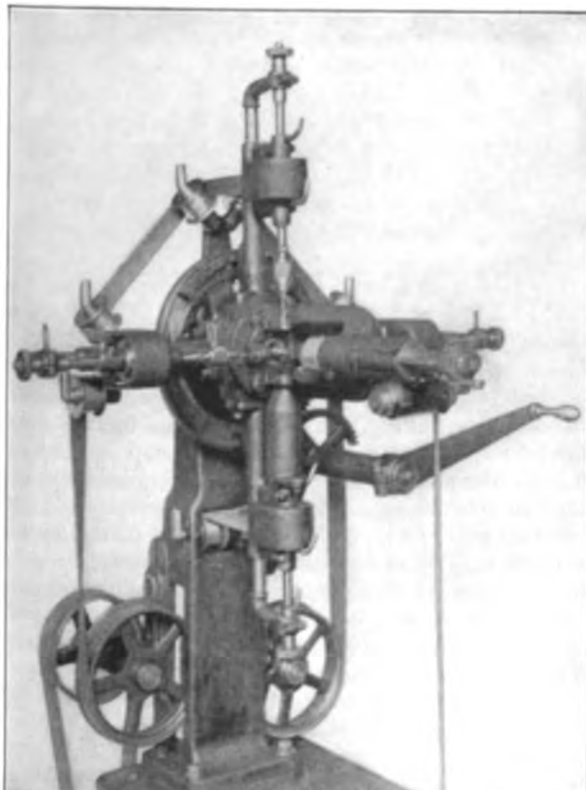


FIG. 1. DRILL FOR FOUR CROSSHOLES

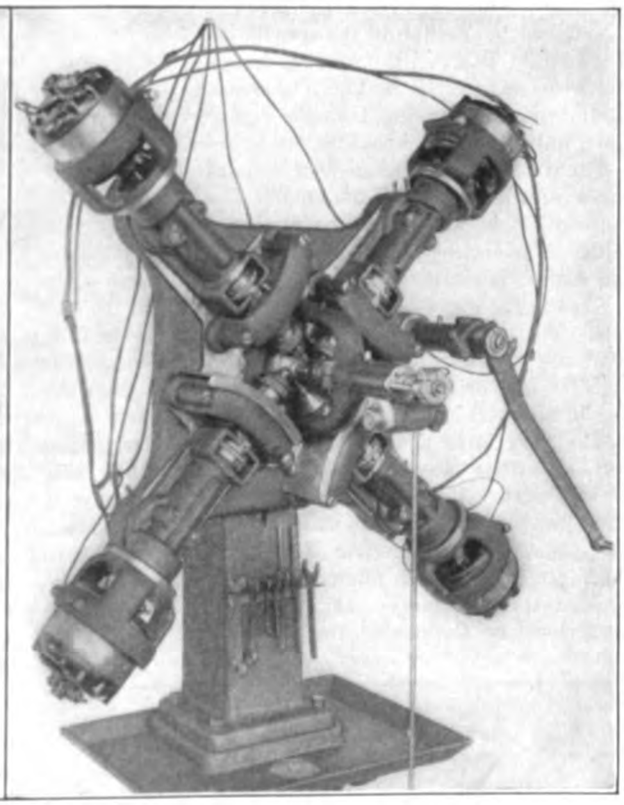

FIG. 2. MILLER FOR FOUR WRENCH FLATS

The spindles run in phosphor-bronze bearings and are driven by pulleys mounted on the ends of the bearings, thereby avoiding the running pressure of the belt upon the spindles. The floor space occupied by this machine is 35x35½ in.; its height is 5 ft. 6 in.; weight, 700 lb.

TWO FUSE-BODY MILLERS

The machine shown in Fig. 2 mills the four flats seen in cross-section *BB* of Fig. 3. The end mills are 0.106 in. in diameter and run at 5,000 r.p.m. The output is 8 per minute, or 480 per hour.

The milling spindles run on ball bearings, and each is driven by a ¼-hp. motor through floating connections to secure free running. The spindles are adjustable

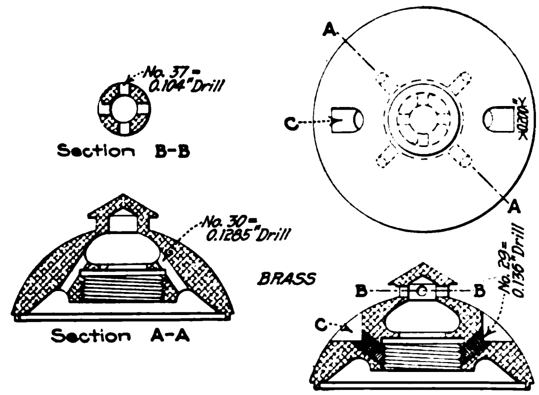

FIG. 3. THE DOMED NUT

longitudinally, and an index graduated in thousandths is provided for fine adjustments to depth of cut. The feed is obtained by oscillating the spindle heads on fulcrums located 12¾ in. from the working center of the machine. The cross-section *BB* in Fig. 3 shows straight cuts, but the milling arcs produced are so slight and the portion being milled so narrow that the cut is practically straight.

The fulcrums are located in eccentric bearings, the throw of which permits the spindle heads to be moved outward so as to make room to remove or insert the mills. The cutting feed is produced by spiral cams having contact laterally with the spindle heads, compression springs in the opposite side being used to return the cutters. The spiral cams are actuated by pinions meshing with one centrally located gear at the rear gear of the machine and driven by a segment gear mounted on the end of the feed-lever shaft.

The work is located on the end of a plunger that is recessed on its face to fit the lip on the circular base of the work. The plunger has also spring pins that enter two of the angular holes so as to bring the cross-holes, shown in cross-section *BB*, Fig. 3, in line with the milling spindles. The plunger is provided with a compression-spring arrangement that pushes it ahead to a position where the pieces can be put in or taken out by the operator. The pieces are held on the end of the plunger during the drilling by a pressure spindle actuated by a foot pedal.

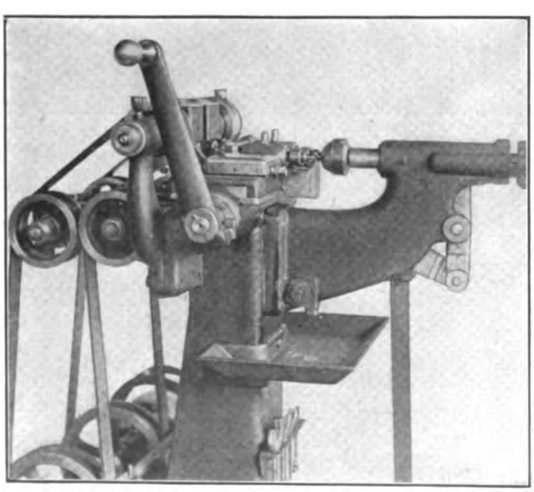

FIG. 4. MILLER FOR TWO WRENCH SLOTS

In operation the piece to be milled is placed on the end of the plunger and turned until the locating pins fall into the angular holes. The work spindle is then advanced with the foot pedal, which pushes the work to its milling position and holds it during the milling. After returning the feed lever the operator removes his foot from the pedal and takes out the milled piece. Guards are provided on the two lower spindle heads on account of chips. The floor space required is 36x33 in.; height 5 ft. 6 in.; weight, 1,200 lb.

Milling Wrench Notches

The two wrench notches *C* in the nut, Fig. 3, are milled simultaneously by the machine shown in Fig. 4. The end mills are 0.200 in. in diameter and are run at 2,500 r.p.m. The output is 5 pieces per minute, or 300 per hour. The milling spindles run in double taper adjustable phosphor-bronze bearings in crossheads mounted on saddles that feed crosswise to the axis of the spindle upon a long slide. They are fitted with ball thrust bearings, and the crossheads are adjustable longitudinally, so that the mills can be set to their required cutting depth. The spindles are driven by spiral gears from separate driving shafts belted over idler pulleys to a countershaft fastened to the column at the rear of the machine.

The feed is by a hand lever mounted on the end of a shaft located lengthwise in the center of the saddle slide. The shaft has short lengths of right- and left-hand threads of coarse pitch that mesh with segment nuts fastened to each of the saddles. Rotation of the shaft will cause the milling heads to feed toward or away from each other in unison. An adjustable stop is provided to limit the amount of feed. The nut is held and located in its milling position by a pressure spindle.

The head of the spindle is recessed to fit the tongue on the base. It also contains two small locating plungers that enter two of the four lower angular holes previously drilled, so that the cuts will be milled midway between the holes. The work spindle is actuated by a foot pedal having a link, lock toggle and segment-gear connection to the spindle. It also has an adjustable stop for the spindle movement of the milling position. A spring abutment bar having a sliding movement and located between the milling spindles is used to hold the work against the pressure spindle while it is advanced to and from its milling position.

The operator locates the work on the head of the pressure spindle and holds it until it comes in contact with the abutment bar. Then he advances the work to its milling position by depressing the foot. The milling is done by moving the hand lever about one-third of a turn downward. After the hand lever is returned to its starting position, the foot pedal is released and the hand held in a position to catch the work as it falls off the head of the spindle and breaks contact with the abutment bar. The floor space is 24x30 in.; height, 40 in.; weight, 600 lb.

The machine in Fig. 5 drills the six angular holes in the aluminum domed nut, Fig. 2. The two upper holes are drilled with No. 29 drills (0.136 in. in diameter) at a speed of 1,875 r.p.m.; the four lower holes with

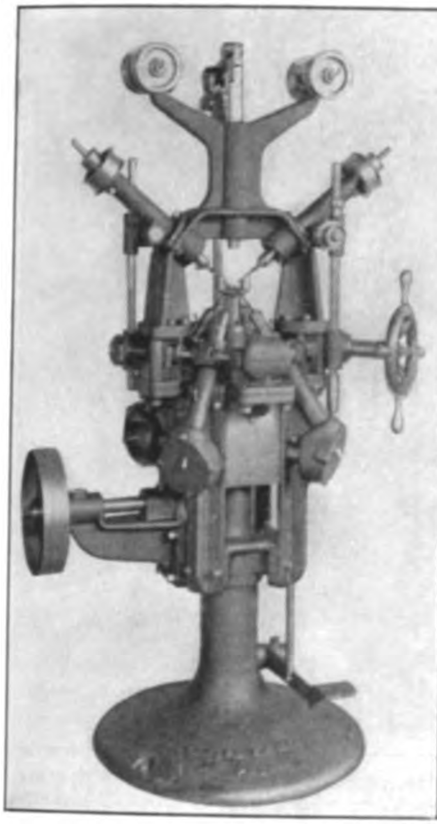

FIG. 5. DRILL FOR SIX ANGULAR HOLES

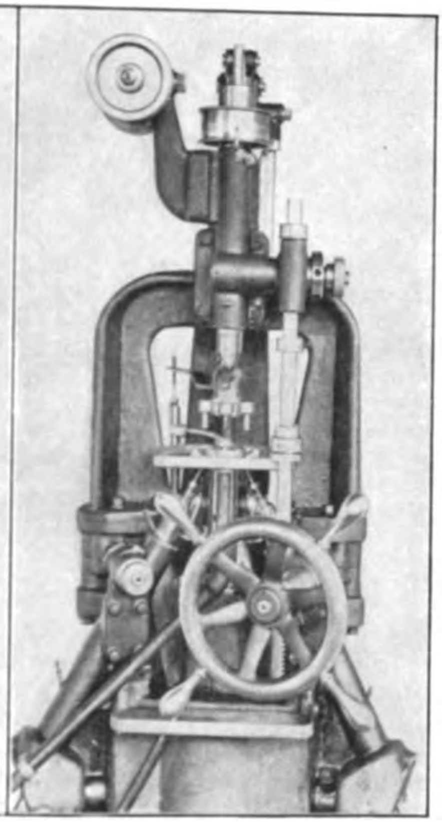

FIG. 6. DRILL FOR FOUR TAPER HOLES

No. 30 drills (0.1285 in. in diameter) at 2,000 r.p.m. The output is 3 per minute, or 180 per hour. A jig with six guide bushings locates the nut. It is set on the top of a post that is adjustable vertically and located on a center common to all the spindles. The piece is held by a pressure plunger actuated by a foot pedal.

The four lower spindles are equidistant and converge to a common center, as do the upper spindles, which are located diametrically opposite each other, but between two of the four lower spindles. The lower spindles are driven through bevel gearing by the main driving pulley, which is belted to a separate countershaft. The upper spindles are driven directly by the countershaft.

All the spindles are fed by the pilot handwheel at the right by a bevel gearing and rack and pinion mechanism. The two upper spindle feeds may be disconnected from the lower so that the drilling positions of each can be adjusted. Each spindle is also provided with a drill collet that is adjustable longitudinally for finer settings and also for making up for the shortening of the drill by grinding. An adjustable stop is used on the vertical feed rack for limiting the drilling depths.

A working table, fastened to the top saddle, but not shown, surrounds the jig on all sides. All gearing is incased, and suitable guards prevent the chips from falling on the lower spindles. The machine is driven by a two-speed countershaft that runs at 500 r.p.m. It occupies a floor space of 42½x28 in. and stands 70 in. high, its weight being 1,150 lb.

The machine shown in Fig. 6 is for drilling the four taper-reamed angular holes at an angle of 29 deg. to the vertical and the No. 24 (0.152 in.) holes in the aluminum upper ring, Fig. 7. The angular holes are drilled with a special drill corresponding to the form of the hole, which is 0.089 in. in diameter on the small end, the other end being tapered to a 12-deg. included angle. These drills are run at 2,500 r.p.m. The No. 24 (0.152 in.) drill was run at 1,875 r.p.m. The output is 2 per minute, or 120 per hour.

The upper ring, Fig. 7, is located in a jig that has four drill guide bushings. It is set on the top of a post that is adjustable vertically. The piece is held by the pressure from a foot pedal. The lower end of the pressure plunger is provided with a locator which carries two guide pins that enter the jig. It also carries a drill guide bushing for the upper drilling spindle.

The four lower spindles are located 72 deg. apart and converge to a common center. The upper spindle is located midway between the first and fourth lower spindles. The four lower spindles are driven through bevel gearing by the main driving pulley, shown at the left of the machine. The upper spindle belts direct to the countershaft. All spindles are fed by the pilot handwheel in connection with a bevel gearing, rack and pinion.

The upper spindle feed can be disconnected from the lower, so that the drilling position of each can be adjusted. Each spindle is also provided with a drill collet that may be moved longitudinally for finer adjustments and for making up for the shortening of the drills caused by grinding. A movable stop on the vertical feed rack limits the drilling depths. A flared-edge pan surrounds the jig on all sides.

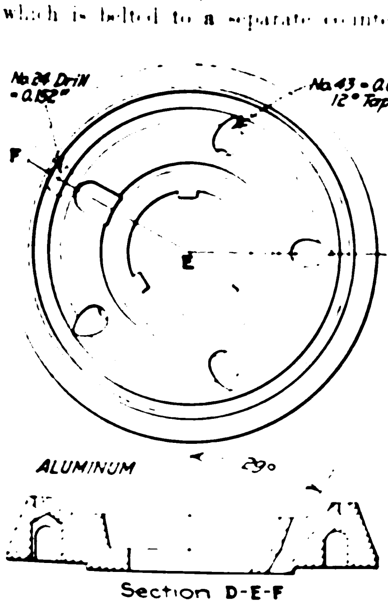

FIG. 7. THE UPPER FUSE RING

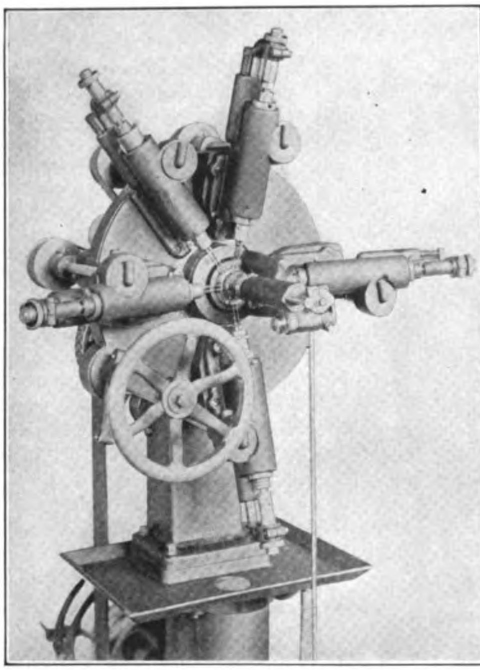

FIG. 8. A 10-SPINDLE DRILLING MACHINE

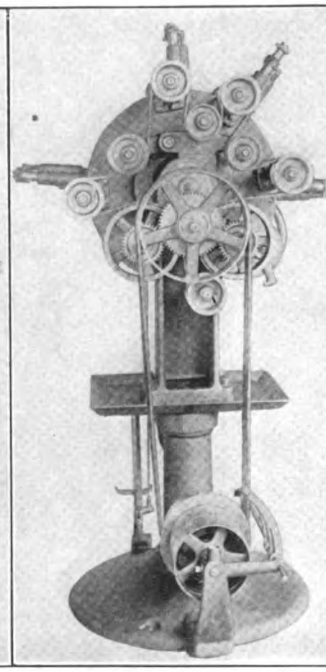

FIG. 9. REAR VIEW OF DRILLER

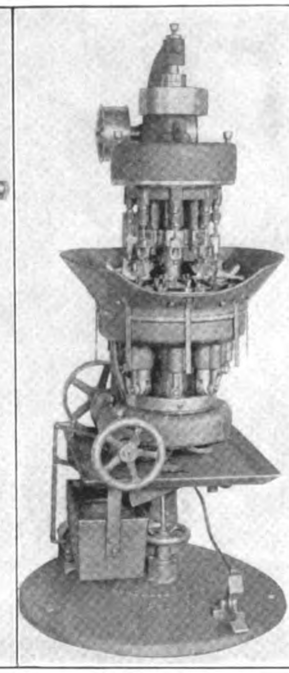

FIG. 12. DRILL FOR THE BODY

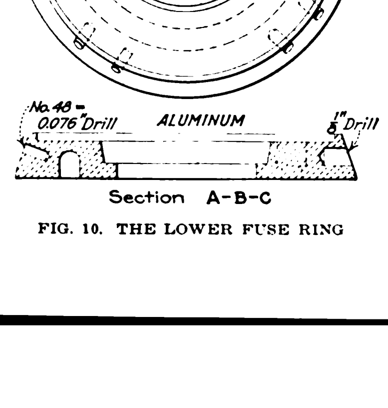
An automatic oil feed has a shut-off that supplies oil to the drills only when cutting. The machine occupies a floor space of 37x28 in.; its height is 5 ft. 9 in.; weight, 1,400 lb.

Side-Hole 10-Spindle Machine

A 10-spindle machine is shown in Figs. 8 and 9. It was designed for drilling simultaneously five groups of two holes each in the beveled face of the lower ring, Fig. 10. Four of the groups are drilled with a No. 48 (0.076 in.) drill, the two holes in each group being 0.348 in. apart and perpendicular to the beveled face. The two holes in the fifth group are ⅛ in. in diameter, 0.315 in. apart and parallel to the circular face. The ⅛-in. drills are run at 2,000 r.p.m. and the No. 48 at 2,500 r.p.m. The output is 6 pieces per minute.



Section A-B-C

FIG. 10. THE LOWER FUSE RING

The work is located in its drilling position by a jig that has a set of two drill guide bushings for each drilling head. It is adjustable on its axis and is provided with a compression and stop arrangement that pushes the jig ahead from between the drills to a position where the pieces can be put in or taken out by the operator. The work is held in the jig during the drilling by a pressure spindle actuated by a foot pedal. All the main drilling spindles are fed by the handwheel at the front of the machine. The handwheel shaft has a pinion that meshes with a rim gear located inside and concentric to the faceplate to which the drilling heads are fastened.

The rim gear carries a segment cam for each spindle head. The cams engage with rolls on the inner ends of the feed yokes, the outer ends of which are clamped to the adjusting sleeves on the outer ends of the main driving spindles. An adjustable stop is used on the handwheel shaft for drilling to the required depth. The main drilling spindles run in sliding sleeves to which a multiple drilling head of two spindles is attached at the inner ends.

The drilling spindles in the multiple heads have adjustable screw collets. The spindles are driven by spiral gears, the driver extending to the rear, and have pulleys on their ends. In order to obtain belt contact, an endless belt is driven by two cork inserted driving pulleys geared to the main driving pulley and belts to the countershaft on the base of the machine, one of the intermediate pulleys being used as a belt tightener. The floor space occupied is 44x40 in.; the height is 5 ft. 10 in.; the weight, 1,661 lb.

For drilling the 0.152-in. hole 0.705 in. from the vertical center line in the upper face of the aluminum body, Fig. 11, at the rate of about 12 pieces per minute the machine shown in Fig. 12 is used. Another ma-

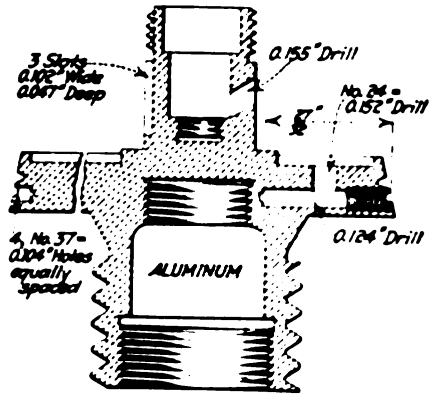


FIG. 11. THE ALUMINUM BODY

chine of the same type, with suitable fixtures, drills also the angular hole 0.155 in. into the side of the stem at the speed of about 12 per minute.

The machine is continuous and semiautomatic in operation. It consists of eight unit spindles disposed equally around and contained in a monoblock casting rotating from left to right around a main vertical shaft, bringing each unit successively in front of the operator for loading and unloading. Each unit has its own drill spindle and driving mechanism, as well as its own work-holding table fixture and table slide. The spindles are driven at about 3,200 r.p.m. by a cotton (fabroil) cut gear meshing with a cut steel heat-treated pinion on spindles. The spindles are stationary as to position.

The work tables are fed upward by a stationary cam around the machine base. This continues until the hole is at proper depth, when the table quickly recedes, pausing at the lowest position to give the operator sufficient time to take the drilled piece out and insert a new blank. The work is held down at each station automatically by a revolving steadyrest with a presser foot that bears firmly against the work as it is raised up against the steadyrest by the table-slide actuating mechanism described, in advance of the drills, during the drilling and until the work has been withdrawn. The steadyrest has hardened bushings that support the drills close to their cutting ends. The floor space required for this machine is 41x28 in.; height, 6 ft.; weight, 2,250 lb.

The machine shown in Fig. 13 is standard, but is adapted for drilling a $\frac{1}{8}$-in. hole $\frac{27}{32}$ in. deep in the flange of the body, Fig. 11, of a Russian fuse. The machine is entirely automatic in operation, except the chucking and ejecting. The output is 12 per minute, or 720 per hour.

This fuse body is made of pressed cast aluminum, finish-turned before being drilled. Aluminum has a tendency to clog and stick to the drill. To avoid this, the feeding of the drills is divided into three steps: The first feed gives half the depth of the hole; the second, three-quarters; and the last, the full depth. The bodies are held in position for drilling by means of a special vise *A*, Fig. 14, having one fixed and one movable jaw. The vises are opened and closed automatically, but can be closed instantly by the operator after the body is put in by the foot pedal shown at the front of the machine.

The ten vises *A* and drilling heads are arranged in units, mounted radially and equidistant upon a continuously rotating carrier, the vises being loaded and unloaded as they pass the operator. The carrier revolves upon a stationary central post driven in and screwed to the top half of the bed. Inside this post is a revolving shaft, driven by a pulley mounted upon its lower end inside the bed and in turn belted over a quarter-turn idler pulley, on the end of the bed, to a separate countershaft.

The carrier is driven by a wormshaft meshing with a large worm gear mounted upon the lower end of the carrier. Fastened to the pulley inside the bed is one of a pair of miter bevel gears that drive the wormshaft by belting. This construction allows a ready means of changing feeds and speeds for different pieces to be drilled. A belt tightener is provided.

Upon the upper end of the shaft is a large bevel gear that meshes with each of the bevel fiber pinions that drive the drilling spindles *C*. The bevel pinions run upon sleeves in the spindle heads *B* and drive the spindles by means of keyed driving collars fastened to the pinions. The feed is accomplished by yokes *D* that clamp to phosphor-bronze bushings *E*, in which the spindles run.

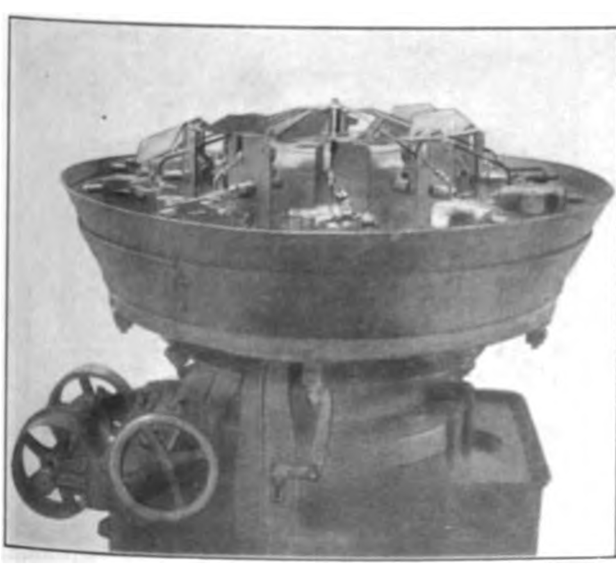

FIG. 13. CONTINUOUS DRILLING MACHINE

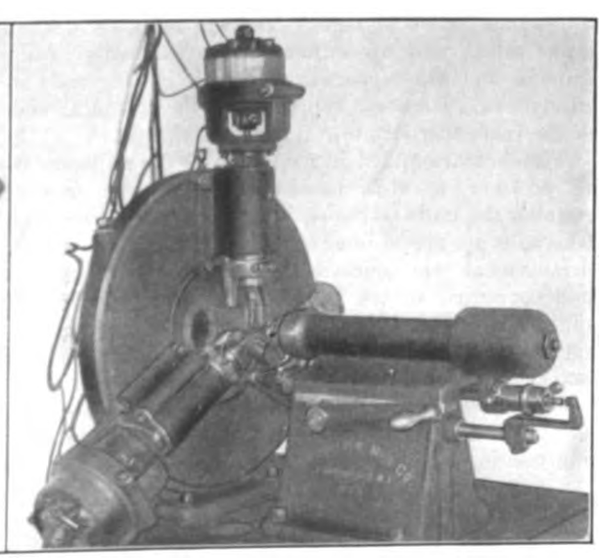

FIG. 15. THREE-SLOT MILLER

On the inner end of the yokes is a roll that contacts with a stationary circular cam fastened to the central post. When the drilling-head carrier *B* revolves around the cam, it causes the spindles *C* to feed in or out. The time taken for a spindle head *C* to travel its cycle is ample

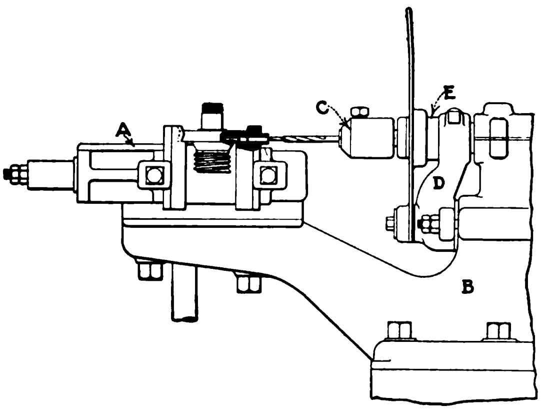

FIG. 14. DETAIL OF DRILLING UNIT FOR PRESSED-CAST ALUMINUM BODIES

to produce any practical feed or speed for drills up to ¼ in. in diameter.

Cutting lubricant is distributed to each drill by individual pipes leading from one main stationary oil pipe that passes up through the central driving shaft and is connected to a force pump fastened to the bed of the machine. The carrier is provided with perforated plates for separating the chips from the lubricant, which is filtered before passing to the reservoir in the lower bed. The floor space is 52x59 in.; the height is 50 in.; the weight, 4,000 lb.

Milling Wrench-Slots

Fig. 15 shows a machine for milling at one operation the three slots spaced equidistant in the neck of the body, Fig. 17. The end mills are 0.102 in. in diameter and run at 5,000 r.p.m. The output is 2 pieces per minute, or 120 per hour. The spindles run on ball bearings, each being driven by a ¼-hp. motor that has floating connections to the spindles. The end mills are held in screw collets that are adjustable longitudinally in the spindles and are supported near their cutting ends by steadyrests. These are supported by the extending ends of the yokes that clamp to the spindle sleeves.

The slots are milled in one cut, and the mills are removed from the cut at the end of the feed, so as to avoid running the mills in the slots on the return of the feed. The mills are moved in or out of the slots by a foot-pedal arrangement that connects to a rim gear located inside and concentric in the faceplate standard to which the milling heads are fastened. The rim gear carries a segment cam for each head, these cams actuating the in and out motion to the spindles by rolls fastened to the yokes that clamp to the spindle sleeves. This clamping permits the milling spindles to be adjusted to their working position. Finer regulation is made with the collets. An adjustable stop is also provided for the rim-gear movement, so as to obtain universal adjustments to the mills, which is very desirable, as it avoids setting each mill separately.

The work is held and located in its milling position by a pneumatically operated chuck mounted on a crosshead with a feed slide. The chuck consists of a projecting expanding mandrel that is opened or closed by the compressed-air cylinder mounted on the rear end of the crosshead. It grips the work in its largest bored end and has a drawing effect that seats the work against the chuck both radially and axially.

The chuck is opened and closed by a compressed-air cylinder, the piston being connected directly to the shell of the expanding mandrel. The air to the cylinder is controlled by a piston valve, which is operated by contact and adjustable dog. The feeding is done by hand by the crank lever shown at the front of the crosshead, and an adjustable stop is provided at the rear for limiting the length of the feed in both directions.

The operator places the work on the projecting end of the mandrel, holding it while he advances the crosshead a small amount. This causes the chuck to grip the works. He presses down the foot lever, which advances the end mills to their cutting depth, and then continues the feeding up to the stop.

Releasing the foot pedal causes the mills to move out of their cuts and returns the crosshead to its starting position, in which the chuck is open and the milled piece can be removed from the chuck. The floor space for this machine is 38x38 in.; height, 65 in.; weight, 1,400 lb.

Another standard machine specially equipped is shown in Fig. 16. This has heads for drilling two No. 37 (0.104 in.) holes 0.652 in. apart in the brass bottom-plug

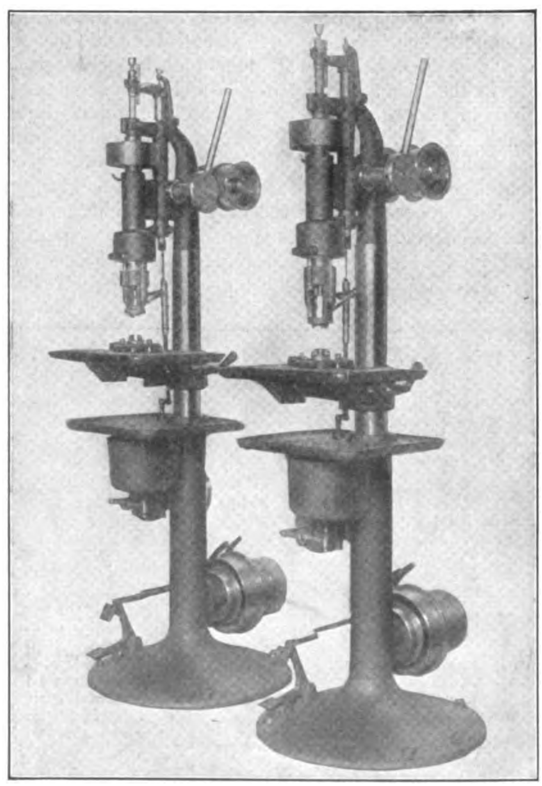

FIG. 16. SPECIALLY EQUIPPED DRILLING MACHINE FOR BOTTOM PLUG AND CHAMBER SLEEVE

body, Fig. 17, and four No. 36 (0.1065 in.) holes 0.376 in. apart in the brass chamber sleeve, Fig. 18. The drills are run at 1,900 r.p.m.

Both pieces are part of a Russian fuse. The output for the chamber sleeves is 15 per minute, or 900 per hour; for the bottom-plug body, 12 per minute, or 720 per hour. Both pieces are centered by a spring steadyrest having a sliding fit on the cylindrical end of the drilling head. In the lower end of the steadyrest is a disk carrying the bushings for accurately starting the drills and also projecting prongs that exactly locate by contact the pieces to be drilled. The pieces are approximately located on the table by a shouldered seat fastened to it.

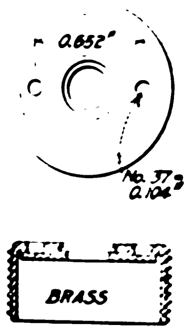

FIG. 17. BOTTOM PLUG BODY

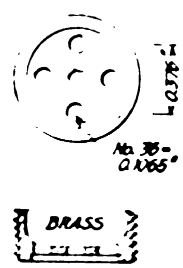

FIG. 18. BRASS CHAMBER SLEEVE

When the output of one piece is sufficient to keep a machine continuously in operation, a machine and head are furnished as a unit. If not, one or more heads with different layouts of spindles can be made to fit interchangeably in one machine. The drill heads with their steadyrests are self-contained and are easily and quickly interchanged. The feed is by a hand lever in conjunction with a rack and pinion. The floor space is 24x30 in.; height, 5 ft. 10 in.; weight, 700 lb. These machines are built by the Langelier Manufacturing Co., Providence, R. I.

Manufacturing with the Oxyacetylene Torch

By Frank H. Nayor

The welding of broken parts by the oxyacetylene method has become, or is rapidly becoming, universal. The preheating of metals by the oxyacetylene flame and running metal into blow-holes in castings or even putting on metal in worn or undersized places are also quite common and are satisfactory when carefully done. The illustrations here given show examples of oxyacetylene welding that can be classed as manufacturing.

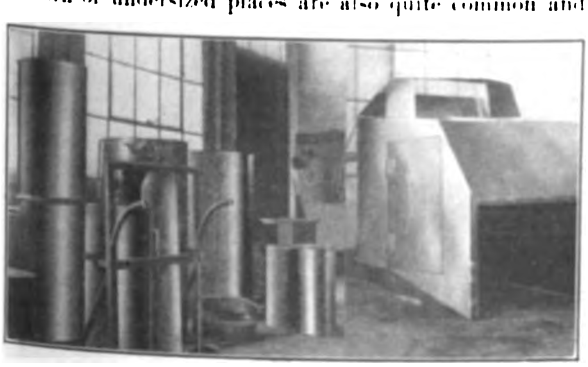

FIG. 1. WELDED SHEET METAL CYLINDERS   FIG. 2. WELDED AUTOMOBILE BODY

Fig. 1 shows some large cylinders made from sheet steel and joined together by welding. An interesting piece of work is illustrated by Fig. 2, which shows a special motor-car body that is cut and assembled from sheet metal by the use of cutting and welding oxyacetylene torches.

In building this body the various parts were first cut out to shape, then held in position where assembled and the corners only of the various pieces welded together. When each part was in position with the observation tower on top, all of the joints were welded.

Punches and Dies for Making Car-Fender Guard Details

By Robert Mawson

SYNOPSIS—These jig and fixture data pages show cast-iron punches and dies used for making a carrier arm outer standard and corner iron of a car-fender guard. The stock is worked hot, being heated in an oil-fired furnace. The article is of especial interest because of the novelty of this use of cast-iron press tools.

In the manufacture of car-fender guard details the Narragansett Machine Co., Providence, R. I., uses cast-iron dies for bending and forming some of the parts. The parts shown are a carrier arm and its corner iron. The manufacture of the first is perhaps of more interest than the second, for it is complicated in shape and requires more operations to produce. The stock is ½x2 in. oval rolled steel.

The first operation forms a hook on one end. This is then bent to an eye. The second bending operation finally forms it into the shape shown in Fig. 7. It is then ready to assemble with the corner iron, Fig. 10, into the finished carrier arm of Fig. 12. The holes for assembling are drilled and the pieces are fastened together by rivets. The use of cast iron for these tools is seen by referring to Figs. 2-A, 8-A and 11-A. In each case either all or the greater part of the tool is of cast iron.

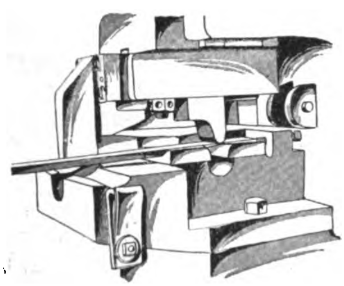

FIG. 2

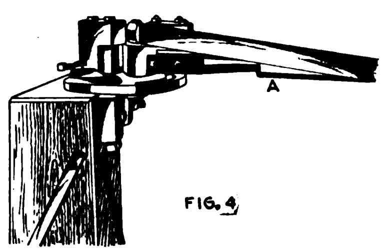

FIG. 4

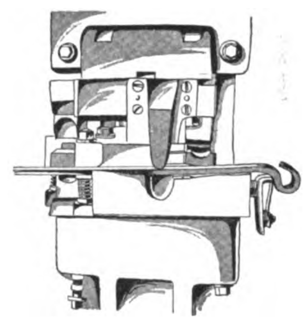

FIG. 6

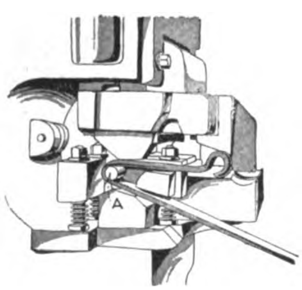

FIG. 8

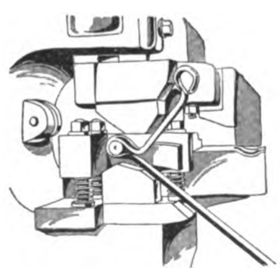

FIG. 9

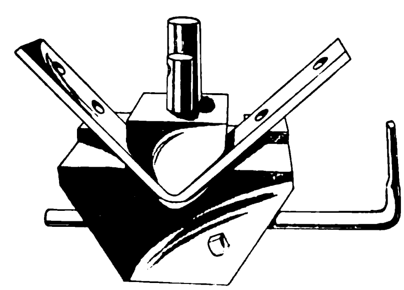

FIG. 11

PUNCHES AND DIES FOR MAKING CAR-FENDER GUARDS, WITH THE WORK SHOWN IN POSITION

FIGS. 2 AND 2-A

Operation—First bending to the shape illustrated in Fig. 1. The stock is placed between the punch and die, being located by an adjustable stop. The punch is then allowed to descend, forming the end of the stock into a loop. This bar is placed in the machine, Fig. 4, the loop fitting over a pin, as shown. The arm A is drawn around and attached to a form block, which, coming in contact with the end of the bar, forces the end to a closed loop, as in Fig. 3.

FIG. 6

Operation—Second die-bending operation to the form illustrated in Fig. 5. The bar is placed on the die, as shown, being located against the adjustable stop at the end. The punch, forced down with the press, forms the bar to the required shape. The carrier arm is then ready to be bent to its final shape, after which it is assembled with the corner iron into the finished carrier arm.

FIGS. 8 AND 8-A

Operation—Bending the bar to the shape seen in Fig. 7. The bar is placed on the pin A, which fits into the loop. The punch, being forced down, pushes down the bar; and as the side of the punch comes in contact with the spring-actuated die, it is also forced down. This movement allows the punch to bend the bar around the die guide block, thus forming the loop in the carrier arm. Fig. 9 shows the piece still in the punch and dies after being formed to the correct contour.

FIGS. 11 AND 11-A

Operation—Bending carrier-arm corner iron, Fig. 10. The stock, which has been cut to length, is placed on the die, being located by the adjustable stop at the end. The punch is forced down, guided by a pin in the die, around which a notch in the punch fits. The carrier arm and corner iron are then drilled. The two units are fastened together with rivets to form the part, Fig. 12.

Laying Out Blanking Dies

By W. B. Greenleaf

Before laying out a blanking die I always cut two or more blanks from cardboard and try various positions, to be sure to cut the metal with as little waste as possible. I find that it pays to take a good deal of care and trouble at this point, for very often a layout that seems to be the most economical is very far from being so.

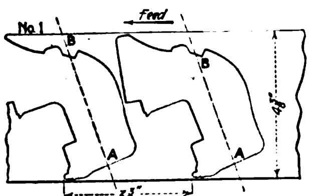

FIG. 1

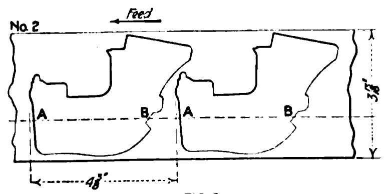

FIG. 2

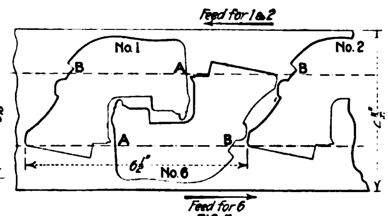

FIG. 3

FIGS. 1 TO 3. THREE WAYS OF LAYING OUT A SHEET-METAL PISTOL STOCK

Figs. 1, 2, 3 and 4 show various trials with this particular piece, in the order in which I made them; I also made at least as many more in between. It will be seen that Fig. 4, the one used, gives 240 blanks and Fig. 1 only 189 from a 36x96-in. sheet, this being a gain of nearly one third. In other words 2⅜ tons of metal will go as far as 3 tons with the first layout. That difference would more than pay for twice as much labor or even in the steel used, in one as the other. As a matter of fact, however, a saving in metal usually means a saving of labor also, as more blanks are obtained from the material handled. In this case the labor at the shear is a little less for Fig. 4, as there are fewer sheets and practically the same number of strips to the sheet at the press. Fig. 1 cuts 9 blanks from each strip in one pass, while Fig. 4 gets 12 blanks but requires two passes through the press, which about evens matters up.

One point to be watched carefully in trying for the best layout is to see that the models are all placed in exactly the same position relative to the strip, for of course they necessarily come that way from the press. In handling an irregular piece like this one shown, I always draw a line (A-B in the illustration) in the same position on all my models and then see that these lines are always parallel with each other in the various trials. If the piece has at least one long straight edge, this can be used and the line is unnecessary.

There is another point which should not be overlooked when the strip has to be passed through twice—this is the stop. If the ordinary stop is used, it will be a source of trouble and delay, for on the second pass, it will enter the hole left by the first pass and stop the strip.

I avoid this trouble by placing the stop in the longest opening of the piece and making it long enough nearly to fill this opening. It then bridges over the shorter opening left by the reverse side of the blank in the first pass. This arrangement is clearly shown in Fig. 4.

It is also necessary to raise the stripper higher than usual, so that the stop may be extra thick and taper down to the usual thickness at the point. If this is not done, the metal will spring down enough for the edge of the first pass opening to catch.

Figs. 5, 6, 7 and 8 show various other layouts for saving metal, with the exception of Fig. 5. I worked over Fig. 5 for some time but could not find a way to avoid excessive waste.

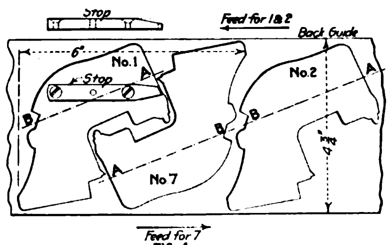

FIG. 4

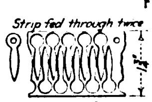

FIG. 6

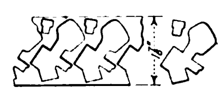

FIG. 7

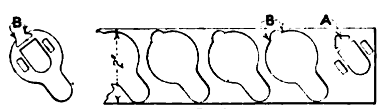

FIG. 8

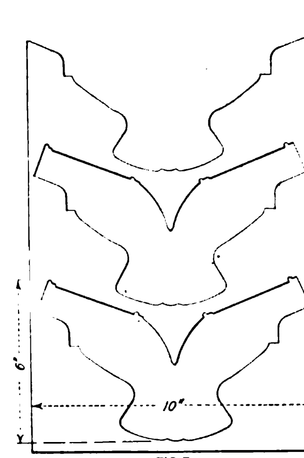

FIG. 5

FIGS. 4 TO 8. OTHER EXAMPLES OF LAYING OUT WORK

Fig. 8 shows a way to get sharp points *BB*. It is old, but may be new to some. If the blanking die were made the shape of the piece, the points would break down and be rounded. To avoid this, the piercing die *A* is put in and the blanking die shears through this opening, as indicated by the dotted line. The resulting points are like needles.

Rules for Power-Plant Tests

The report of the Power-Test Committee of the American Society of Mechanical Engineers has just appeared in a pamphlet of 215 pages, 6x9 in. Included are boilers, reciprocating steam engines, steam turbines; pumping machinery; compressors, blowers and fans; complete steam power plants, locomotives; gas producers; gas and oil engines and waterwheels.

The report represents the work of many prominent members of the society for a number of years, and a permanent committee has been appointed to interpret the rules when called upon to do so. The information has been carefully prepared and is given in considerable detail.

Rational Design of Foundation Anchor Plates*

By Terrell Croft

SYNOPSIS—In this article are given formulas for the designing of anchor plates and bolts. Two methods have been used in practice. Both are described in detail. Tables are also given and illustrations of the plates and bolts and the methods of using them.

The functions of anchor plates are, it has been stated, two—(1) to hold the bolt head or nut of the anchor bolt from turning; (2) to transmit the stress imposed on the bolt to an ample area of masonry of the foundation.

In the design of anchor plates simple forms should be adopted. This is particularly true when the plates are to be of cast iron, which is the material most frequently employed, so that the patterns will involve a minimum of labor. There is no necessity for the complicated shapes sometimes encountered. The design should preferably be such that no coring is necessary in the molding. Furthermore, where a line of anchor plates is being made for bolts of different diameters, the plates should increase in size by regular increments as the bolt diameters increase; that is, the plates should be proportioned in accordance with the loads which will be imposed upon them, as will be explained in the following paragraphs.

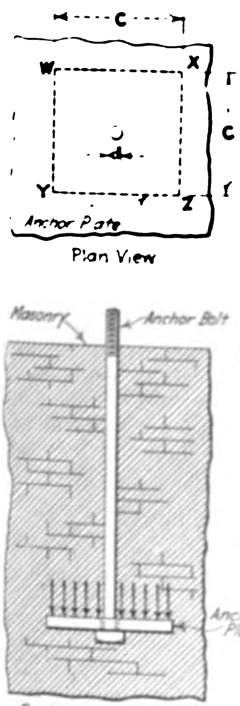

FIG. 1. ANCHOR PLATE AND BOLT SET SOLID IN MASONRY WITHOUT CASING

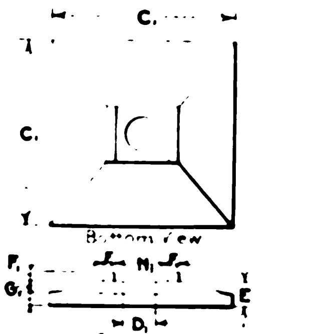

FIG 2. FOUNDATION ANCHOR PLATE WITH LUGS TO PREVENT NUT FROM TURNING

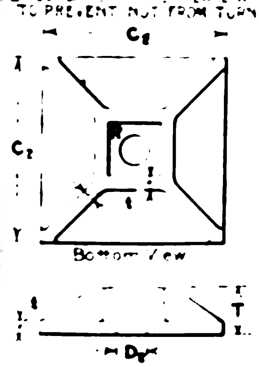

FIG 3. ANCHOR PLATE WITH RECESS TO ACCOMMODATE NUT

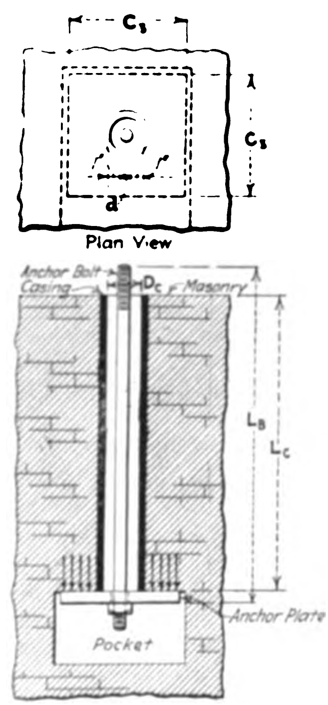

FIG 4. ANCHOR PLATE AND BOLT IN FOUNDATION WITH CASING

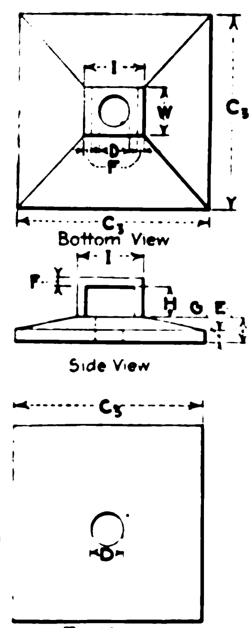

FIG. 5. CONSTRUCTION FOR FOUNDATION ANCHOR PLATE WITH POCKET FOR NUT

RATIONAL DESIGN OF FOUNDATION ANCHOR PLATES

Anchor plates are usually square, Fig. 1, because the patterns for this form are readily made and also because the pockets, where such are provided in foundations, are ordinarily of this shape. Hence a square plate is accommodated more effectively than a round one would be. Round anchor plates may be and have been used under certain conditions.

Methods of Proportioning Plates

Two different methods of proportioning foundation anchor plates have been used in practice. By the first method all dimensions are determined by employing empirical formulas for which the diameter of the anchor bolt is used as a basis. By the second method the bearing area of the plate $WXYZ$ (Fig. 1) is computed in such a way that it will be great enough so that the safe crushing strength of the material against which the plate presses will not be exceeded when the bolt is stressed to its safe tensile strength. Thus the length of side C may be determined. Then the other dimensions of the plate are figured by using empirical formulas. An example of each of the foregoing methods will be given, and then additional formulas—(23) and (30)—in accordance with the second method will be suggested whereby anchor plates may be proportioned to satisfy any required condition. Proportions for two complete lines of plates designed in accordance with these formulas—(23) and (30)—are given in

Table 1. One line is adapted for use in "built up" masonry foundations, while the other is for monolithic concrete foundations.

An example of design based on anchor-bolt diameter is expressed by the following equations—(1) to (6-A)—

from the article by A. D. Williams in *American Machinist,* Vol. 27, page 1715. The symbols refer to those of Fig. 2, all dimensions being in inches.

d = Diameter of bolt (diameter of rod, not diameter at root of thread) (1)

$C_1 = 8d$ (2)

$E_1 = 0.5d$ (3)

$F_1 = 0.375d$ (not over 1 in.) (4)

N_1 = Width of nut or heads across flats $+ 1/8$ to $3/8$ (square nuts or heads are usually used on lower ends of bolts) (5)

$$D_1 = \begin{cases} d + 1/8 \text{ for } 7/8 \text{ bolts and smaller} \\ d + 1/4 \text{ for } 1/4 \text{ to } 2\tfrac{1}{2} \text{ bolts} \\ d + 3/8 \text{ for } 2\tfrac{3}{4} \text{ and larger bolts} \end{cases} \qquad (6)$$

Depth of washer below top of foundation $= 50d$ (6-A)

All dimensions are to be made to the nearest eighth of an inch.

An example of design based on the diameter of the bolt and the safe bearing strength of the foundation material (S. H. Bunnell, *American Machinist,* Vol. 26, page 869) is outlined in the formulas—(7) to (11)—which follow. The symbols refer to Fig. 3, all dimensions being in inches.

d = Diameter of bolt (7)

C_2 = Length of side computed as outlined later (8)

$T = C_2 \div 4$ (9)

$t = (C_2 \div 20) + 1/8$ (10)

$D_2 = d + 1/8$ up to $1\tfrac{1}{8}$ bolt and $+ \tfrac{3}{16}$ above (11)

The proportions given in Table 2 apply to Fig. 3 and were computed by using the preceding formulas—(7) to (11). The bearing area of the plate was calculated in each case so as to provide a pressure of 50 lb. per sq.in. on the foundation masonry when the bolt is stressed to 10,000 lb. per sq.in. sectional area at the root of the thread. The square recess R should be so proportioned that the bolt head or the nut will fit loosely in it. This design has the feature of simplicity to recommend it, inasmuch as the pattern requires no corework. It is not, however, as convenient a design for applications where the anchor bolts are to be removable; that is, where they have nuts on their lower ends.

Anchor-plate dimensions should preferably be based on the diameter of the anchor bolt at the root of the thread rather than on the outside diameter of the rod

TABLE 2. ANCHOR-PLATE PROPORTIONS

(All Dimensions Are in Inches)

Size of Bolt	5/8	3/4	7/8	1	1 1/8	1 1/4	1 3/8	1 1/2	1 3/4	2	2 1/2	3

of which the bolt is made. That this is true is obvious from the fact that the tensile strength of the bolt is determined by the area at the root of the thread and not by the cross-sectional area of the unthreaded rod. In Table 3 are given the sectional areas of rods of different diameters and also the areas at the roots of standard U.S. threads. The equations which follow for proportioning anchor plates recognize the fact that the ratios

TABLE 3. AREAS AND DIAMETERS OF U. S. STANDARD THREADED RODS

d Diameter of Rod	A Area of Rod	a Area at Root of Standard Thread	Q^2 Ratio of a to A, that is, $\frac{a}{A} = Q^2$

4	12.566	9.993	0.792

14.534 ÷ 20 = 0.7267 = Average.

between the overall diameters of the rods and the diameters at the roots of the threads vary for different sizes of rods. The following discussion indicates how compensation is made for this condition.

Ratio of Diameter of Rod at Threaded End

The ratio of the diameter of a threaded rod at the root of the thread to the diameter of the unthreaded rod may be expressed by the equation

$$\frac{d_r}{d} = Q \qquad (12)$$

Hence,

$$d_r = Qd \qquad (13)$$

Where

d_r = Diameter at root of thread of U.S. standard threaded rod in inches;

d = Diameter of the unthreaded rod in inches;

Q = Ratio of d_r to d.

The ratio of the cross-sectional area of a threaded rod at the root of the thread to the cross-sectional area of an unthreaded rod will (since areas vary as the square of the diameters), it follows from equation (12), obviously be expressed thus:

$$\frac{d_r^2}{d^2} = Q^2 \qquad (14)$$

The last column in Table 3 gives, then, the values for Q^2 (Q^2 = ratio of area at root of thread to area of round rod unthreaded) for the rods of different diameters.

These values for Q^2 vary from 0.646 for a ½-in. rod to 0.792 for a 4-in. rod, with an average of 0.727. However, in the equations which follow, in which the average value of Q^2 is used, 0.723 is taken rather than the true average value (0.727), so as to favor slightly the smaller-diameter bolts. How these values of Q^2 are applied will be shown in a paragraph under equation (22).

An expression for the safe tensile strength of an anchor bolt is

$$S_b = 0.7854 d_r^2 T \qquad (15)$$

where

S_b = Safe working tensile strength of a round anchor bolt in pounds;

d_r = Diameter of a U.S. threaded bolt at the root of the thread;

T = Safe unit tensile strength of the material of the bolt in pounds per square inch.

The expression for the safe bearing strength of masonry upon which an anchor plate without a casing presses is (refer to Fig. 1)

$$S_{m1} = M(C^2 - 0.7854 d^2) \qquad (16)$$

where

S_{m1} = Safe bearing strength of the area of the masonry pressed upon by any anchor plate not associated with a casing, in pounds;

M = Safe unit bearing strength of the masonry or material upon which the anchor plate bears, in pounds per square inch;

C = Length of side of the square anchor plate used without a casing, in inches;

d = Outside diameter of the bolt, in inches.

Safe Bearing Strength of Masonry

An expression for the safe bearing strength of masonry upon which an anchor plate with a casing presses is (Fig. 4)

$$S_{m2} = M[(C_2^2 - 0.7854(d+2)^2] \qquad (17)$$

where all of the symbols have the meanings previously noted, except

S_{m2} = Safe bearing strength, in pounds, of the area of the masonry pressed upon by an anchor plate with which a casing is used;

C_2 = Length of side of the square anchor plate used with a casing, in inches.

The internal diameters of the casings ordinarily used around anchor bolts are equal to the diameters of the bolts + 2 in., which accounts for the expression $(d + 2)$.

Equations for the safe proportions of an anchor plate used on a bolt without a casing, as in Fig. 1, may be determined thus: Obviously, if the bolt is stressed to its safe strength when the anchor plate exerts the safe pressure on the masonry,

$$S_b = S_{m1} \qquad (18)$$

or, substituting (15) and (16) in (18),

$$0.7854 d_r^2 T = M(C^2 - 0.7854 d^2) \qquad (19)$$

or, simplified,

$$C^2 = 0.7854\left(\frac{d_r^2 T}{M} + d^2\right) \qquad (20)$$

But from equation (13) $d_r = Qd$; therefore,

$$C^2 = 0.7854\left(\frac{Q^2 d^2 T}{M} + d^2\right) \qquad (21)$$

or

$$C = 0.886 d\sqrt{1 + \frac{Q^2 T}{M}} \qquad (22)$$

But since Q^2 may, for all practical purposes—see paragraph under equation (14)—be taken as 0.723, the working equation becomes, in inches,

$$C = 0.88\ d\sqrt{1 + \frac{0.723 T}{M}} \qquad (23)$$

The proportions for anchor plates designed in accordance with equation (23) have not been computed for this article, inasmuch as the majority of anchor plates are probably not set without casings, as in Fig. 1, but are used with casings, Fig. 4, in which case equation (30) applies. It should be noticed that, if the anchor plate presents ample bearing area when used with a casing, it will have a considerably greater factor of safety when used without the casing, as in Fig. 1.

The equations for the safe proportions of an anchor plate when it is used with a casing follow. If the masonry upon which the plate presses and the anchor bolt are both to be stressed to their safe load, then

$$S_b = S_{m2} \qquad (24)$$

or, substituting (15) and (17) in (24),

$$0.7854 d_r^2 T = M[(C_2^2 - 0.7854)(d+2)^2] \qquad (25)$$

or

$$C_2^2 = 0.7854\left[\frac{d_r^2 T}{M} + (d+2)^2\right] \qquad (26)$$

But from equation (13) $d_r = Qd$; hence,

$$C_2^2 = 0.7854\left[\frac{Q^2 d^2 T}{M} + d^2 + 4d + 4\right] \qquad (27)$$

or

$$C_2 = \sqrt{0.7854\left[d^2\left(\frac{Q^2 T}{M} + 1\right) + 4(d+1)\right]} \qquad (28)$$

But since the working value of $Q^2 = 0.723$,

$$C_2 = \sqrt{0.7854\left[d^2\left(\frac{0.723 T}{M} + 1\right) + 4(d+1)\right]} \qquad (29)$$

or

$$C_2 = 0.886\sqrt{\left[d^2\left(\frac{1 + 0.723 T}{M}\right) + 4(d+1)\right]} \qquad (30)$$

in inches.

Safe Working Strength of Bolts

The safe working tensile strength of mild-steel bolts has, for the computations of the values of C_2 in Table 1, been taken at 7,000 lb. per sq.in.; that is, the value of 7,000 was substituted for the symbol T in equation (30).

The safe bearing strength of masonry—M in equation (30)—for the first column under C, Table 1, was taken as 70 lb. per sq.in., this being the safe compressive load permitted for dimension stones in cement mortar under the Chicago building laws, which apparently are more stringent than those applying in other cities. For example, in New York a safe compressive load of 300 lb. per sq.in. is permitted on Haverstraw brick laid flatwise. The values in the second column under C_2 in Table 1 were computed on a basis of a safe load of 200 lb. per sq.in., which may be taken as a safe permissible load for concrete foundations of a 1 : 2 : 5, or richer, mixture.

The method of designing a line of anchor plates the proportions of which are given in Table 1 (see Fig. 5 for the anchor plate) was first to compute the length of the side of the plate C_3 by utilizing equation (30). Then the minor dimensions were computed by using the empirical formulas given in Table 4. In so far as is known there is no refined method, which will stand the test of practicability, for computing the thickness of a cast-iron anchor plate. The plate must be heavy enough so that it will not crack, even if it is stressed severely by being forced against an uneven surface. Practice has shown that, if the thickness of the plate at the center is equal approximately to the diameter of the bolt in inches, it will be strong enough; hence the thickness of the plates of Table 1 was figured on this basis. The other proportions indicated in Table 4 were also selected largely

TABLE 4. CONSTANTS USED IN DERIVING ANCHOR-PLATE PROPORTIONS

Symbol	Dimension Designation	How Proportioned (All Dimensions in Inches)
d	Outside diameter of bolt (not diameter at root of thread)	Determined by probable load that will be imposed on it
D	Diameter of bolt hole	= d + [illegible] in. when d is [illegible] in. or under; [illegible] in. when d is 1 in. to 2½ in.; [illegible] in. when d is 2¾ or over
C	Length of side	= Computed with equation (30)
F	Thickness of pocket wall	= 0.375d
E	Thickness of plate at center	= d
G	Thickness of plate at edge	= 0.5E
H	Inside height of nut pocket	= Thickness of rough nut + [illegible] in. when d is [illegible] in. or under; [illegible] in. when d is 1 in. to 2½ in.; [illegible] in. when d is 2¾ in. or over
W	Outside width of nut pocket	= Width of rough nut across flats + [illegible] in. when d is [illegible] in. or under; [illegible] in. when d is 1 in. to 2½ in.; [illegible] in. when d is 2¾ in. or over
I	Outside length of nut pocket	= W + 2F

on the basis of what experience has indicated to be satisfactory.

Where such procedure appears desirable, one may, when designing a line of anchor plates, use the exact value of Q^2, as tabulated in the fourth column of Table 3, for each diameter bolt. These exact values of Q^2 would be substituted in either equation (22) or (28). This should, theoretically at least, give results of somewith greater accuracy than does the method—equations (23) and (30)—used for the computation of the C_3 values in Table 1. However, since Table 3 may not in many cases be available, the working equations given in (23) and (30) are the more convenient forms. They are sufficiently accurate for all practical work, inasmuch as the other variables that enter into the problem will probably introduce greater errors than will the application of this approximate working value (0.723) for Q^2.

Saw Guard on Hand Miller

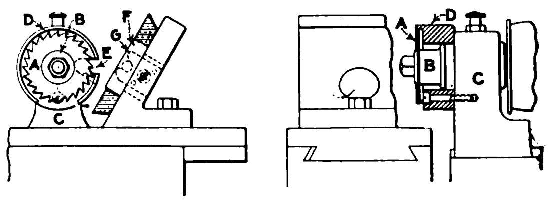
By D. Baker

This guard was designed to keep the operator's fingers from coming in contact with a saw running at high speed. The guard was put on a bench miller used for sawing off the end of a brass pin that was screwed into the side of a time-fuse ring.

The illustration shows the saw at A, on the saw arbor B, while C shows the miller head. The guard D is made of a piece of cold-rolled steel 1½ in. in diameter, turned out as shown for clearance for the saw, and it fits over the front bearing of the machine. When held in position by the one screw shown, the guard overlaps the saw about $\frac{1}{32}$ in. At E the guard is cut away for clearance, to permit the pin on the work to pass through to the saw, the cut being filed away on an angle so as to allow the scrap to drop away readily, as shown by the dotted line.

In operation the time-fuse ring is placed over the stud F, and the end to be cut off is located in proper position by the slot in a hardened piece G. It is held in place with the left hand while the right hand operates the lever that carries the table with the work, forward against the cutter.

In first trying out this machine we used the regular commercial screw-slotting cutters, but they dug into the



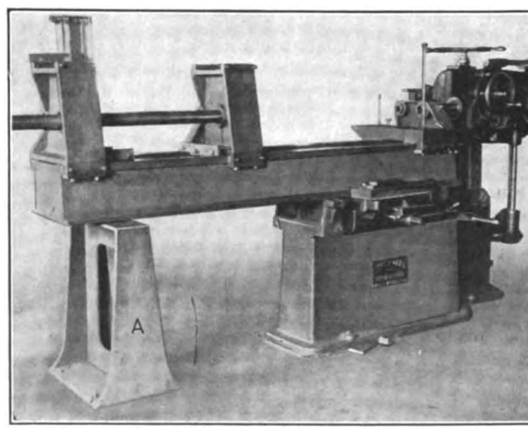
SAW GUARD ON HAND MILLER

work and clogged up with chips. We overcame this trouble by grinding clearance on the sides and reverse rake on the teeth, so that the teeth would have a tendency to throw the chips away rather than to gather them in. The capacity of the machine is from 6,000 to 10,000 pieces in 10 hr.

Supporting an Overhanging Table Fixture

By E. A. Thanton

In boring out bearing holes in Millholland turret lathes the work is done on a boring mill with a table too short to support the overhang of the work and fixture. The method of remedying this condition is shown in the illustration. The cast-iron support A is placed close to



SUPPORTING AN OVERHANGING TABLE FIXTURE

the outer end of the overhang, and rollers are provided so that it will move easily across the top of the support, according to the way the machine table is run. Leveling screws, resting on iron plates, are placed near the four corners of the bottom of the support, so that it may be adjusted to the correct height and leveled.

Methods and Tools Used in Machining Tractors

EDITORIAL CORRESPONDENCE

SYNOPSIS—Some of the tools used for machining elements employed on tractor machinery are shown. The jig for drilling the balance weights is of the indexing type, thus machining the holes in the correct alignment. An interesting babbitting die for making white-metal bearings is also shown. An indexing jig is used for machining a six-sided turret. This tool is first utilized for drilling the holes in the correct position and later employed for rough-boring and facing operations. A fixture for milling four sides of a casting squarely is also of interest.

The A. B. Farquhar Co., Ltd., York, Penn., manufactures a variety of tractor and agricultural machinery. Fig. 1 illustrates a jig used for drilling the balance weights for crankshafts. The casting is previously milled along the surfaces, which fit against the sides of the crankshaft webs. The balance weight is then placed in the jig, being forced against the wall *A* with the setscrew *B*. The jig is swung over to the two position for drilling, the locations being obtained by the pin *C* in bushed holes *D*. The drills are guided through bushings *E* so that the holes will be in the correct alignment. A view of the jig, with the casting in position ready for drilling, is shown in Fig. 2. It illustrates the method employed to locate the casting, how it is held, and the indexing arrangement.

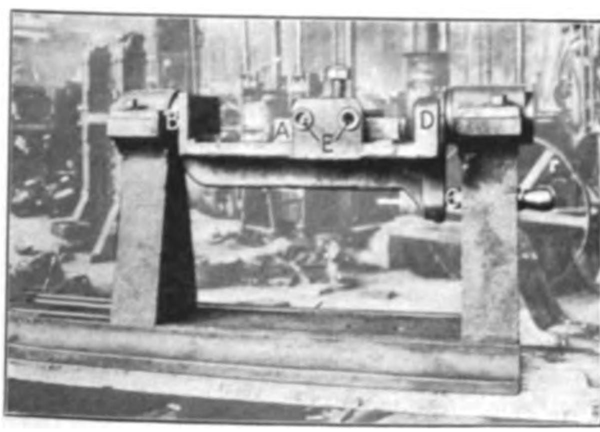


FIG. 1. DRILL JIG FOR BALANCE WEIGHTS

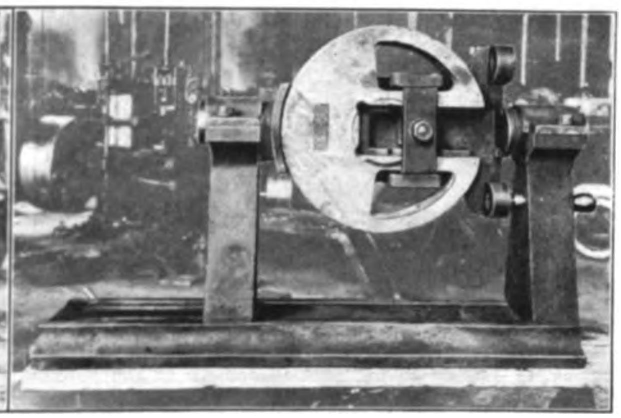

FIG. 2. JIG WITH CASTING IN POSITION

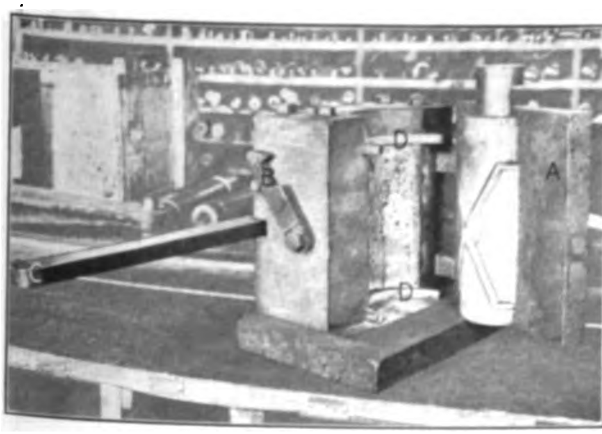

FIG. 3. BABBITTING DIE OPEN

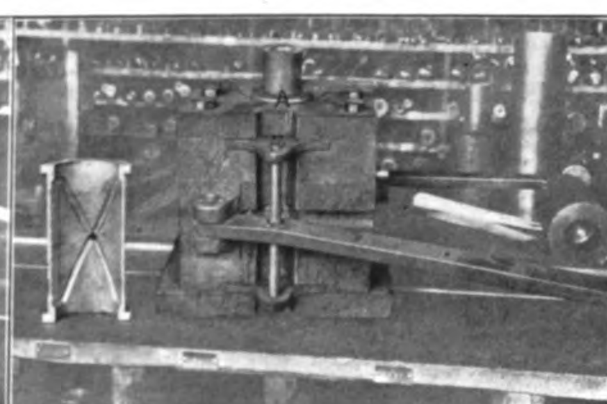

FIG. 4. BABBITTING DIE CLOSED

Babbitting Die for Bearings

On some of the steam- and gas-tractor engines certain of the bearings are made of white metal. The die used for making these bearings is shown in Fig. 3. The cover *A* is swung back and held with the latch *B*. The molten metal is then poured into the mold and the bearing made.

After the metal has solidified, the cover is opened, which draws the handle *C* forward. This forces out the ejectors *D* and pushes out the finish-molded bearing. The die, closed, is shown in Fig. 4. The metal is poured into the tool at *A*. One of the molded bearings is shown at the left of the die, and its good appearance is worth noting.

The A. B. Farquhar Co. has recently been doing some special work, a part of which was making horizontal turret lathes.

FIG. 5. JIG WITH CASTING REMOVED

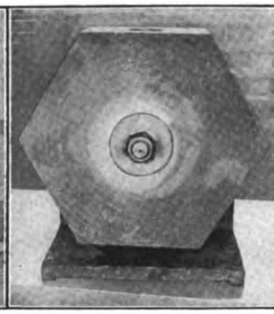

FIG. 6. DRILL JIG WITH CASTING IN POSITION

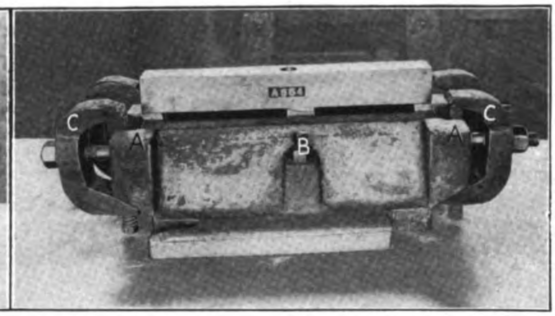

FIG. 7. MILLING FIXTURE FOR SIDE BLOCKS

Fig. 5 shows the jig used in drilling the turret. The ring *A* is removed from the main body of the jig and the turret casting placed in it, being located by the machined recess in the jig. The various holes are then drilled, the tool being guided through bushings *B*.

The ring *A* is placed in the jig as shown and the casting inserted in the jig, which is located by the arbor *C*, the latter fitting into the hole previously bored. The casting is held in position with the washer and nut. The jig is then placed on the table of a Bullard boring machine and the turret holes rough-bored and the surfaces faced. The various positions are obtained by index pins which fit into bushed holes. By this method the turret holes are machined in alignment with the previously drilled holes. The turret is attached to the machine for the final boring of the holes.

Fig. 6 shows the jig with the turret casting in position ready for the boring operation.

Milling Side Blocks

The fixture used in milling the four sides of the side blocks is shown in Fig. 7. The rough casting is first placed on the blocks at *A* and rests on the adjustable screw *B*. Owing to the beveled surface at the bottom, the clamp *C* when tightened not only holds the casting but also draws it down to the locating surfaces.

The upper surface is then milled and the casting placed in the fixture as shown, being located on finished pads. The part is held down with the clamps as described. A gang of milling cutters is then fed over the casting and the upper surface and sides are straddle-milled. In this way the four sides are machined in alignment with two settings of the fixture.

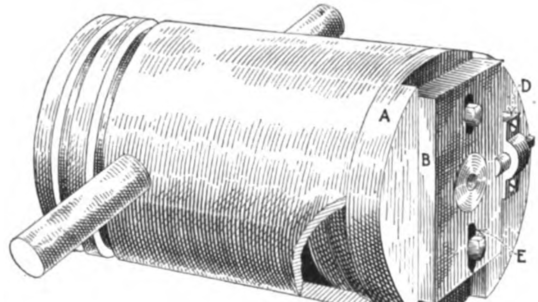
Correcting Errors of Boring in Wristpin Holes

By O. M. Chapman

In the machining of pistons for either gasoline or Diesel oil engines too much attention cannot be paid to having wristpin holes in perfect alignment with the center line of the piston. It is possible to bore wristpin holes within 0.003 to 0.005 in. of square with the center line of pistons up to 18 in. in diameter or over; but when a positively accurate job is wanted, the following method is advisable:

Make up an aligning arbor to fit the finished wristpin holes in the piston. The protruding ends of the aligning arbor should be of a suitable length and ground to a uniform diameter for indicating purposes. The work is then ready to mount on the adjustable center shown in the illustration and to be ground on the outside after it is trued up with the wristpin hole.

The adjustable center has a disk *A*, which can be of any convenient size to suit the piston. This disk has a place milled central to receive the part *B*, which carries a hub with a center. The plate is secured to the disk by two or more bolts *E*. The part *B* is moved on the disk by an eccentric, which is carried in a bearing *D* bolted to *A*. Elongated slots should be milled in *B* to facilitate the adjustment of the center. A slot should also be milled in *B* to receive the eccentric. The outside diameter of the fixture should be turned to fit the pistons after the fixture has been completely assembled with the eccentric set at its neutral point. A slot should be milled in the outside edge of the plate *A* to facilitate its removal after grinding a piston.



PISTON-ALIGNING FIXTURE FOR CORRECTING ERRORS IN WRISTPIN HOLES

The bottom end of the piston should be bored a suitable distance and size to accommodate the adjustable center, which is so placed that the eccentric will throw the piston to correct any error. The aligning arbor should be checked with an indicator while rotating the piston on the grinder centers, until the same reading on the dial of the indicator is obtained at each contact. The bolts are then tightened in the adjustable center, and the piston is ready to be ground.

This fixture has worked out very satisfactorily and is recommended to anyone who is looking for a method of finishing pistons accurately. And it should not be forgotten that it is lack of accuracy in such details which prevents the best results being secured under trying conditions. The best results require good workmanship at all times.

Specifications for Purchase of Leather Belting

SYMPOSIUM OF DISCUSSION

SYNOPSIS—A discussion of the article published on page 683, from the viewpoint of the leather-belting manufacturer and users. The difficulty of formulating satisfactory specifications is pointed out, variations in hide leather are outlined, and the desire of the manufacturer to produce a reliable product is emphasized. Tensile strength, pliability, thickness and weight are discussed in detail.

The Manufacturer's Viewpoint

BY LOUIS W. ARNY*

The article appearing on page 683, entitled "Specifications for Purchase of Leather Belting," is remarkable for the intelligence with which the author has dealt with a subject that is so little understood and concerning which there is so much misinformation. From the point of view of the leather-belting manufacturer there are but few corrections to be made and few additional thoughts to offer.

Though leather belting is one of the oldest means of power transmission, there has never been discovered or invented a real substitute for it. Its flexibility and its ability to adapt itself to the pulley, the large quantity of power which it will transmit under favorable conditions, the readiness and cheapness with which it may be repaired or altered, the fact that it may be made endless, the small amount of attention it requires and, further, its remarkable durability and length of life, its salvage value when no longer serviceable as a belt, all commend it strongly as a most satisfactory instrument.

The general disposition to reduce to specifications all the purchases of well-organized concerns has led to efforts to prescribe minutely not only the points of quality, but the methods of manufacture. These efforts have proved such obvious failures that a consideration of the subject is timely and may be profitable.

The real point of difference between the belt maker and those who have prepared the specifications is that the technologist is ignorant of the material and the product, and that the belt maker, with an intimate practical knowledge of the manufacture of leather belting, the material of which it is made and usually of its practical use, is deficient in a knowledge of the technology of the subject. Hence, they (technologist and manufacturer) "do not speak the same language." Until the belt maker can lay aside his business long enough to take up the study of the scientific side of the use of belting or until the theorist will devote several years to a practical study of tanning, currying and beltmaking, they cannot hope to view the subject from a common standpoint.

The fundamental error of the technical people is the presumption that leather is a homogeneous product of the same quality throughout, like so much iron or fabric. The practical currier and belt maker know that every hide is as individual as the animal on which it grew, that its quality is beyond the reach of cultural effort, that no two hides are exactly alike any more than human faces are alike and that every strip of leather cut from a given hide is different in thickness, texture, strength, stretch and wearing qualities. It seems impossible to prescribe in figures any stated requirements that will secure the best and reject the least fit. The "feel" of the expert currier remains superior to any specifications that any engineer has been able to formulate. Further, it is impossible for the belt maker to submit to any physical test every strip of leather that he intends to put into a belt, or even one strip from every hide, and the latter test would be worthless even were it feasible.

THE NEED OF PRACTICAL KNOWLEDGE OF LEATHER

There is no method known by which one not trained in the school of practical experience can determine from its appearance whether a given strip was located within ten inches or twenty inches of the backbone; in fact, there are many stories current of the ludicrous mistakes certain engineers have made in identifying even the backbone itself, and there are few of them who could differentiate with any certainty between a well-finished belly or shoulder strip and "the first cut off the backbone." It is similarly impossible to determine from the appearance of the belt whether the leather is tanned with all bark or part bark and part extract (even experts may be deceived in some results of exclusive extract tannage), whether the butt was classified as No. 1 or No. 2, whether the hide was a packer native steer, a country hide or a South American, whether the strips were stretched in straight-edge clamps, by hand or by power, or even whether they have been stretched at all.

This confirms the conclusions of your correspondent that the inclusion in specifications of requirements that cannot be identified or proved in the finished product are futile and serve only to complicate the problem. As he says, it is not a question of how the belt was made, but of the service that it will render. Of course, the underlying thought is that a belt made according to stipulated methods which are thought to be the best will produce better results; but in stipulating methods that are not necessarily the best and the use of which cannot be determined by any examination of the product and in calling for material that cannot be identified the buyer is compelled to depend as his only resource upon his confidence in the ability and the honesty of the seller, and he might better have relied upon such confidence in the first place rather than waste his time on impossible specifications. It is notorious in the leather-belting trade that many large buyers have some very poor belting in their storerooms and in their shops, notwithstanding the very rigid specifications which many of them have adopted. Those who have been more fortunate in securing good service can attribute it more to the ability and honesty of the belt maker than to any merit in the specifications under which the belting was bought.

*President, National Association of Leather Belting Manufacturers.

Instead of depending upon the honor of the seller, they in a manner absolve him from responsibility by setting up their specifications and their inspection and testing departments, and then buy from the lowest bidder at prices that make it manifestly impossible that they should get the qualities they specify. It is not intended to excuse the seller who contracts to deliver one thing and substitutes another; but there is never much sympathy wasted on the poor fool who in the hope of getting something for nothing loses his money by betting that the pea is under a given shell, when the disclosure shows it to be elsewhere. The sympathy of the leather-belting trade does not go out to the Government because it has been deceived, when its published prices of contracts awarded show that it sometimes pays less for its finished belting than the material specified would have cost in the rough.

Importance of Buying from Dependable Houses

There may be invented for the purchase of leather belting, specifications that will be practical and that will accomplish their purpose, but it is quite certain that those in use at this time are not accomplishing this purpose. Until this invention is made, the only method by which the intelligent buyer, desirous of spending his money to the best advantage, can hope to secure satisfactory qualities of leather belting is by buying recognized brands of belting from dependable houses and taking good care to pay them enough money for it to have it made right. It will be observed that there are two propositions here, the first to buy from houses in whom the buyer has confidence.

There are 150 manufacturers of leather belting scattered over this country, practically all of them honorable, reliable men, with a keen appreciation of the desirability of making permanent customers by rendering good service, and an arrangement could be made with any of them by which a really superior product would be delivered; but the second proposition is more important, that there shall be paid for leather belting such prices as will enable the maker to make it right and to maintain his qualities. The buyer has no right to expect to get something for nothing, or much for little, or to get more than his dollar should actually buy. When he buys on specifications that he cannot enforce, he is simply placing temptation in the path of the seller, who would much prefer to play fair, and inviting him to commit a fraud. The ethics of the leather-belting trade are as good as those of any other line of manufacture, better than most others, but the men engaged in the line are human and are ready to defend themselves against sharp practice if necessary. As long as belting is bought on price, the shops will be full of poor stuff that cannot possibly render service, regardless of the specifications under which it has been bought.

Most of the belting manufacturers have standard grades and classifications, making a range of belting suitable for every duty. Most of them have established prices on these several grades, which prices form a standard market price that is always subject to the keen competition of 150 manufacturers. There is never any difficulty for any buyer accurately to determine this market price, and there is never the possibility that competition will permit this price to go too high. From the very nature of the case there never can be a combination on price among the leather-belting manufacturers, though there is an "open-price association" through which information is disseminated regarding the prices at which sales have been made. There is therefore absolutely no reason why any buyer should not be able to purchase leather belting that will give maximum service, if he will place himself in the hands of some good belt maker and will pay him a fair market price.

Tensile Strength—Any dependence upon a test for tensile strength in belting leather has always been unwise (a) because of the wide divergence in the tensile strength of corresponding strips cut from different hides of the same class and also of different parts of the same strip; (b) because the least desirable of the strips that may be cut from a good hide—those near the belly—will usually show the greatest tensile strength; (c) because the most desirable strips that may be cut from the hide—those immediately over the backbone—usually show less tensile strength; and (d) because the greatest possible load to which a belt may be submitted in the transmission of power bears so small a proportion to its tensile strength.

Nor is it necessary that the "ultimate tensile strength should be as high as possible." A belt of any appropriate width and quality never breaks from lack of strength, but always because of an accident, a lack of elasticity or of a rotten condition due either to old age or lack of care. When a properly tightened belt in good condition is overloaded beyond its capacity to transmit, it jumps the pulley, if it can; and this point is reached long before the strain upon it makes any approach to the ultimate tensile strength of its weakest strip.

It does not seem to be understood by engineers that the qualities of tensile strength and stretch are inseparable, that when by any means the stretch is reduced, the tensile strength is reduced with it and that the strip of satisfactory tensile strength necessarily shows a large "stretch." It is quite true, as stated, that belts of approved quality will show an elongation much in excess of the 8 to 12½ per cent. specified and that under a tension of 2,000 lb. most of them will show an elongation of from 20 to 30 per cent. It is further true that belts showing an elongation of 30 per cent. under a tension of 2,000 lb. will usually produce better practical results, as belts, in transmission qualities and in length of service than those which stretch but 8 per cent., though the latter may be less troublesome in the matter of tightening while they last. But, as stated, these facts bear but little relation to the elongation in service under a tension of 100 to 200 lb.—not nearly so much as does the matter of the placing of the belt upon the pulley under that proper degree of tension which is necessary if the belt is to transmit its load properly; but this factor is one generally under the immediate control of the engineer and not of the belt maker, and hence an appropriate point for the engineer to start at in his specifications.

Pliability—Buyers have always been willing to accept a feeling of firmness and even hardness as an indication of good quality, and a few years ago, in an effort to meet the demand, belting leather was finished much harder than at present. The fashion in belting has changed, and leather with a solid but mellower "feel" today has the call; for ordinary transmission such leather is more suitable. But the question of pliability is closely connected with that of the diameters of the pulleys over which the belt is to run, and one that is sufficiently pliable to run to the best advantage over a 6-ft. diameter pulley may be entirely unsuitable and unsatisfactory over a 6-in. diameter pulley.

It is probably more rational to consider that a good hide tanned to show a gain of about 60 per cent. and curried and stuffed to show no loss in weight is in best condition for the widest range of transmission, so far as its pliability is concerned, and that any adaptation to small pulleys which may be desirable should be made in the thickness of the belt rather than in any attempt artificially to increase its flexibility. Attention should be called here to the fact that, as with tensile strength and stretch, the least flexibility is to be found in the best part of the hide—over the backbone—and the greatest flexibility will be found in the least desirable part of the hide—the belly. The effort to set up a test of bending over a 1-in. rod is futile so far as backbone cuts or belly cuts are concerned, and it is extremely doubtful whether any test can be devised that will convey accurate information regarding pliability to one who does not know leather.

THE IMPORTANT FACTORS OF THICKNESS AND WEIGHT

Thickness and weight are two most important factors that should be dependent one upon the other. It is true that the weight can be increased; but it is doubtful that "white lead or other heavy material" is ever used, the most common resource being a heavy grease stuffing, which instead of being a detriment is an advantage to the belt and can be criticized only on the score that it may be constructively an attempt to deceive.

Single leather belts are made in medium, heavy and extra-heavy weights or thicknesses, the actual weight specifications per square foot varying slightly with the different makers. In doubles the practice varies, all makers offering light, medium, heavy and extra-heavy double belts, but some making them definite fractions of the inch in actual thickness without regard to the weight and others to specified weights for each thickness. There has been so much talk about weight that buyers have absorbed the idea that the best belt must weigh approximately 16 oz. per square foot for singles and 32 oz. for doubles. It is obvious that, so far as the quality of material only is concerned, a belt weighing 14 oz. may be just as "good" as one weighing 16 oz., or that a light double belt may be just as "good" as the heavy double belt. A specification of weight then does not secure for the buyer any better quality, but only more quantity.

The question of weight is not one of quality, but of adaptation for the service; and it should be understood by belt users that the principle involved is a thick belt for large diameters, a medium-thick belt for medium diameters and a thin belt for small diameters. As leather belting is usually made, this would dispose of the question of pliability, would secure the best possible pulley contact and transmit the largest load. It might serve to clarify this point if the belting manufacturers would issue a table showing the brands of their belts as adapted to given pulley diameters; but until there is secured some more uniform practice in designing pulleys, belts and power requirements of machines, the manufacturers would be courting trouble.

There is an opportunity for the greatest possible service to all concerned in the formulation of some standard practice in the calculation of the power transmission of all kinds of belting, which could be generally accepted by engineers, designers and belt manufacturers and in accordance with which all machinery could be built. At present every designer is a law unto himself, and he oftentimes places upon his machines pulleys of such narrow widths and small diameters that no belt can transmit the required load in a satisfactory manner—an endless source of trouble to the owner, the operator and the maker of the belt.

It is quite probable that the leather-belting manufacturers would be glad to coöperate with any of the mechanical-engineering societies which would undertake this task, or that they might establish their own engineering bureau to determine these points so little understood, as suggested by your correspondent; but in the meantime nothing is to be gained for the buyer by the imposition of absurd specifications, for in the present trend of thought on the part of the belting manufacturers the feeling is that such business as is covered by these silly specifications is not worth having. In a number of recent cases some of the best houses have refused to bid on contracts where the specifications were impracticable.

Substituting Second- for First-Grade Belting

By CARL G. BARTH

I have read the article on page 683, "Specifications for Purchase of Leather Belting," with a great deal of interest, for it is indeed high time that something be done to get developed and put into general use some such rational specifications and tests as the writer suggests.

I fear that the present state of the art of selling and buying leather belting is even worse than the writer of the article has presented it; for from what I have had occasion to see of it during the last 15 years I should judge that the average salesman in the business has about as much chance for a blessed existence in the hereafter as has a camel of passing through the eye of a needle, unless his final judge will make a full measure of allowance for the adverse conditions under which he labors and against which his own oft-tried honest efforts to improve them have only too frequently redounded to his material disadvantage.

I have in mind the fact that in many industries those intrusted with the purchase of leather belting know absolutely nothing else about the matter than to award a contract to the lowest bidder who says he will furnish good belting; and that the shop management is so lax that no systematic attention is paid to the belts, so that the whole institution is left in ignorance about the true state of affairs.

I have it from a prominent manufacturer, now dead some eight or nine years, that the cut-throat competition in the business had brought about a condition of affairs, some years before I came in touch with him, that led to a suggestion that all manufacturers combine to cease the making of first-grade belting and that they simply offer second grade for first grade, so as to get on a more equal basis in their competition with one another, in connection with the lower prices for which the majority of purchasers had been led to believe that they were entitled to first-grade belting.

The general condition of the market is such that most purchasers are getting only second-grade belting while believing that they are getting first grade; and this because the would-be-honest salesmen have practically all given up getting the purchasers to pay the necessary price for first-grade belting, as some of the originally less

scrupulous among them have been able to make the purchasers believe that they could offer first-grade belting for the same price as the absolutely honest among them demanded for their second grade.

This is of course only a review of what has happened in all cases of sharp competition, and it seems a pity that manufacturers and salesmen who wish to be honest—and surely they are greatly in the majority—should not be able legally to combine to maintain their honesty and in connection with this to avoid the temptation that comes with monopolistic combinations.

However, they can greatly improve their lot by combining to develop rational specifications and methods of testing, for such would enable them to compete fairly and squarely on the merits of their product.

In spite of the higher price the best belting now made is by all odds the most economical in the long run, if reasonable care is taken to prevent accidents to belts. Hence, in the distant future when all users get to understand this and to act upon it the belt manufacturer may be confronted with the problem of finding a market for his inferior grades of belting, which he now must produce and sell along with his best grade, in order to keep the price of the latter from soaring too high.

Specifications of a Large User

By C. B. Auel*

It must be admitted, as stated in the article on page 683, that there is room for improvement in leather-belting specifications generally, and to this simple statement of fact nearly everyone will agree, whether from the standpoint of consumer or manufacturer. However, we are inclined to feel that the article, while containing certain incontrovertible features, does not lead very much nearer to the ideal specification.

As something that has met requirements for several years past, having been slightly modified since its original publication, we offer our own belting specification. It may be of interest to your readers to indicate how it was developed. We first wrote out what we knew about the subject, as well as what we could obtain from various books; after that we communicated with a considerable number of large consumers of belting like ourselves, requesting similar information and stating what our object was in so doing. When the replies were received, the data were tabulated in suitable form, so that a composite belting specification was the result, but of course one prepared wholly from the standpoint of the consumer. Copies of this tentative specification were then submitted to many of the belting manufacturers throughout the country, with a letter inviting their frankest comments, regardless of whether such were favorable or otherwise. In consequence much added information was obtained, though the replies were extremely varied, some stating the matter should be left wholly to the belting manufacturer, others changing or modifying the temporary limits that had been set, suggesting new paragraphs, etc. The final result was the specification given here.

Criticism of the specification as it stands may be made by some belting manufacturers in that the laps for double belting could be safely reduced from 4 in. to 3 in. and the weights specified altered to allow a variation both above and below the figures set, say 5 per cent. and 3 per cent. respectively, instead of permitting a variation above only, as has been done by the use of the word "minimum."

Reference to the specification will, we believe, show that it has been prepared along the lines indicated; that is, neither from the wholly "theoretical" nor the purely "practical" side, but as a compromise between them.

Without going into any detailed discussion of the article in question, a few comments on some of the statements made may be in order. While it is true that it is desirable to state the essential features of a specification such as "explicit requirements based on the service expected" and "definite tests to show whether the requirements are met or not," it may be pertinent to ask what these should be as applied to belting used in a work having a considerable number of belt-driven machine tools and where belting after its purchase can only be turned into stock for general use. As to

Westinghouse Electric & Manufacturing Company

East Pittsburgh, Pa.

LEATHER BELTING

1—This specification covers miscellaneous sizes of leather belting for general use.

I—PHYSICAL PROPERTIES

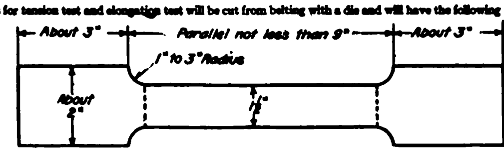
2—The belting must be of the best quality oak-tanned leather, free from all ingredients in any way injurious to the life or wearing qualities of the belt, or that simply add to its weight. Material

3—Belting must be cut longitudinally and no piece of hide must exceed 54 inches in length. Widths less than 7 inches are to be cut within 15 inches of the center of the hide; widths 7 inches and over are to be cut from the center of the hide; neither shoulder, belly, side, nor flank stock, nor any padding nor shimming will be permitted. It must be of uniform thickness and width, and be perfectly straight from end to end. Location of Cuts

4—Laps must not be less than 4 inches or more than 8 inches, excepting that in single belting 8 inches and over in width, the lap may be 1 inch longer than the width of the belting; no lap should be within 4 inches of the end of a strip. Laps must be thoroughly cemented, and when pulled apart the exposed surfaces must not show any resinous, vitreous, oily or watery condition; no rivets will be permitted. Laps

5—Belting must have an ultimate tensile strength, both in the leather and in the splice, of not less than 3600 pounds per square inch and must not show an elongation in 2 inches to exceed 13½ per cent when measured under a load of 2250 pounds per square inch for one hour. Tests

Test pieces for tension test and elongation test will be cut from belting with a die and will have the following dimensions:



6—Belting must not crack open on the grain side when doubled strongly by hand with the grain side on the outside, nor must it show piping or raising on the grain side when similarly treated with the grain side on the inside.

7—When belting is required for any special purpose, the manufacturer will be notified as to the nature of the work, maximum horse-power, speed, etc.

II—WEIGHTS

8—Belting not waterproofed must come within the following range of weights which must be guaranteed to be not more than 10 per cent in excess of the actual weight of the leather. Weights

Width	Minimum Wt. Per Sq. Ft. Single Belting	Double Belting
1" to 2"	13 oz.	24 oz.
2¼" to 4"	14 oz.	26 oz.
4½" to 5½"	15 oz.	28 oz.
6" and over	16 oz.	28 oz.

III—MARKING

9—The belting must be marked every 10 feet with the manufacturer's name, trade mark, or equivalent identification mark. Marking

IV—REJECTION

10—The Westinghouse Electric & Manufacturing Company reserves the right to reject any portion or all of the material which does not conform to the above specification in every particular, and to return the rejected material to the manufacturer or seller for full credit at price charged f.o.b. point of delivery specified by the purchaser. If the material is to be replaced, a new order will be entered at prices, terms and conditions acceptable to the purchaser. Rejection

*Director of standards, processes and materials, Westinghouse Electric and Manufacturing Co.

the further statement that "tensile strength should be specified in pounds per inch of width," we cannot see that the use of "per square inch" involves any detrimental feature that "per inch of width" does not. Tensile strength in a belt is not so important compared with some other features, since practically all properly selected and installed belts are operated well within their factor of safety.

Regarding the statement that the best brands of belting show from 16 to 25 per cent. stretch, we venture the statement based on our own experience and methods of testing that the best brands, when ready for the consumer, do not show such maximum stretch.

It would certainly be desirable, as the article states, if a definition for "pliability" could be worked out, perhaps combining it with "piping," but in this connection it is advisable to point out that the best portion of the hide—the center of the back—is less pliable than is the poorest portion, which is the belly. What is needed as much as pliability is a soft finish for good pulley contact.

"Weight" is specified not only to prevent the use of light-weight stock, but also to eliminate objectionable and excess filling, and it indirectly involves thickness, which need not therefore be mentioned; though if not, something should be said as to uniformity or tolerance in thickness.

Experience on the part of belting manufacturers, as well as of consumers, shows that for best average results as to wear, strength, etc., the leather should be selected from certain portions of the hide only and will then approximate certain weights per square foot with certain resulting tensile strengths per square inch. If, as seems to be suggested in the article, such features as weight and thickness were both to be removed from a belting specification and "strength per inch of width," in effect, substituted for them, it would seem to remove desirable safeguards, especially to the small consumer, who is not always so situated as to be able to make tests for tensile strength and who is therefore more nearly dependent on weight, thickness and visual inspection tests against the use of belly, flank or other undesirable portions of the hide.

A Few Suggestions

By N. G. Near

The writer of the article on page 683 hits the nail squarely on the head. There is no reason why specifications cannot be considerably bettered; and as I have had some little experiences with belting and have delved into belting and transmission economics, perhaps I can write something helpful.

Strength—"Tensile strength should be specified in pounds per inch of width" is the logical specification, but the buyer should state at the same time the pulley diameter, the speed in feet per minute and other conditions that might be deleterious to thick belts or belts made of other materials than leather. I know one manufacturer, for instance, who will not sell woven belting for a drive on which there is a finger shifter, and he will not allow his belting to go onto pulleys that are too small.

Stretch—In my experience I have found that stretch is not so serious as often painted. If a belt is properly cared for and kept in a properly pliable condition, it need not be maintained as tight as where it is not pliable, but is dry and hard. Here, again, much depends upon conditions. If the drive is a vertical one, there should be as little stretch as possible. If the drive is horizontal and if the distance between centers is great, the matter of stretch is of little moment. We have many examples of leather drives that have operated for 18 and 29 years without being touched by a knife.

Pliability—A good rough-and-ready specification for pliability is, "The belt must be so pliable that it will run——inches slack on——foot centers and transmit——horsepower while running at a speed of——feet per minute. It is well, of course, to give the pulley sizes and speeds and state which is the driving and which the driven pulley. Where the drive is a small one and the belt a narrow one, it would hardly pay to give all details of this kind; but where there are many drives of this type in a given shop, pliability could easily be tested in this way on *one* drive, and it would be taken for granted that all belting in the batch is equally pliable.

Thickness—Since a thin belt will transmit proportionately more power per square inch of section than will a thick belt, this is an important item. Where belting is bought by the pound, considerable money can often be saved by specifying a thin belt (tolerance to be stated with the thickness) and running it on wider pulleys.

Weight—Weight is important on horizontal drives, but not on vertical drives. On horizontal drives the heavier the belt the better, especially for short drives, for then little difficulty is experienced in permitting the belt to run slack and embrace a large arc of contact on each pulley. A heavy belt runs more steadily, does not flap, wabble and wave. Still, as the author states, belting should not be sold or bought by the pound. Strength is the most important thing, and on that the price should be based. The only reason why a belt of zero weight would be desirable is that such a belt would be immune to the effects of centrifugal force; but since such belts are impossible and weight is inevitable, let us use belts that are heavy rather than light. For horizontal drives, therefore, I should specify heavy belts.

Piping—This is an insignificant point and need not be thought of if the directions of the manufacturer of belting are followed. Thin belts should be used on pulleys of small diameter. The larger the pulleys become in diameter the thicker may be the belt. Here are rules that I have recommended in this connection:

For single-ply belts $\frac{3}{16}$ in. thick, pulley should not be less than 6 in. in diameter.

Double-ply belts $\frac{3}{8}$ in. thick, pulley should not be less than 10 in. in diameter.

Triple-ply belts, $\frac{9}{16}$ in. thick, 3-ft. minimum diameter.

Four-ply belts, $\frac{3}{4}$ in. thick, 4-ft. minimum diameter.

Scientific Management Course

With the aim to acquaint those interested with the most recent developments in the theory and practice of scientific management, Frank B. Gilbreth announces the fourth summer course from July 31 to Aug. 12.

The course is open to professors of engineering, business administration, psychology, economics and other subjects allied to management. There are no fees and those desiring to attend should make application to Frank B. Gilbreth, 77 Brown Street, Providence, R. I.

Preparing for Manufacturing Munitions in the U. S.

By A. B. Chester

All who have given any thought to the question of industrial preparedness recognize its importance. A very valuable part of military preparedness is the governmental encouragement during times of peace to the munitions industry. It is of course needless to point out the inestimable value to the Germans of the Krupp establishment. The same kind of establishment might be built up in this country, say at the Bethlehem Steel Co., the Midvale Steel Co., the Crucible Steel Co., the Remington Arms Co., and so on. In order to do this, however, it will be absolutely essential for these factories to enter the world market for ammunition and other war supplies.

It seems to me that our Government and our Government representatives should encourage and assist in every possible way the obtaining of orders by such companies in foreign countries. In this way we can provide in the munitions industry a large body of trained workers that would enable us not only to produce large quantities of munitions at the beginning of war, but rapidly to expand to meet the colossal demands of modern war for guns, ammunition, etc. The trained worker, it seems to me, is a tremendous asset.

A Perpetual Industrial Inventory

An industrial inventory is very desirable, because if properly taken and properly analyzed, it will show our capacity for production of various war supplies. I very much doubt whether it would be feasible to draw up and keep alive any plan for immediately developing our maximum output. Indeed, such development would be impossible within any short period of time, as has been abundantly demonstrated by England, France and the United States. It does seem to me, however, not only possible, but desirable and even necessary to make plans for the immediate placing of definite orders as soon as war breaks out. The firms with which these orders are to be placed should be determined in advance and full drawings, specifications, tools, fixtures, gages, etc., should be on hand and ready for delivery to the manufacturers with whom the orders are to be placed. This procedure, together with and in addition to the orders that could be immediately placed with private concerns engaged normally in the manufacture of war munitions, would give us a very large immediate increase of output and would form a solid basis for further expansion.

Few private concerns, except those normally engaged in the manufacture of munitions, will be prepared to turn out complete articles such as guns and gun carriages, projectiles, cartridges, powder, etc. It will therefore be necessary to provide in advance places where the various component parts shall be delivered for final assembly. Such places would naturally be in the vicinity of such industrial centers as Philadelphia, Pittsburgh, Chicago, etc.

Centralized Assembling Plants

Take, for instance, the manufacture of shrapnel. There is at the Frankford arsenal in Philadelphia a small plant for the manufacture of shrapnel. In case of war the arsenal would be taxed to the limit of its capacity and would immediately commence to expand. Its permissible expansion is, however, very definitely limited. In Philadelphia and vicinity there are large numbers of machine shops, each of which could be called upon to manufacture one or more parts of the shrapnel.

It would seem to me a good plan to have the capacities of such shops examined by the officers at the Frankford arsenal and a decision reached as to the orders for components of the shrapnel that would be placed with these various firms. In the vicinity of Philadelphia, but separate from the Frankford arsenal, could be established an assembling plant to which the parts of the shrapnel manufactured by the shops in the vicinity should be delivered. This new assembling shop should have the free run of the Frankford arsenal and benefit by all its experience. In this way, without interfering at all with the output and enlargement of the arsenal, a new plant with very considerable capacity could soon be built up. It seems to me that all plans for such an assembling shop could easily be made in advance. The same thing could be done for the manufacture of shells in the vicinity of Pittsburgh and other cities.

Conversion Table for Changing Pounds Into Kilograms

By H. Le Roy Brink

It is necessary on all foreign shipments to have the packages marked with weight in pounds and kilos; and as our foreign trade has been increasing right along on account of the war, this table is being used considerably. It occurred to me that some of your subscribers who are shipping material to Europe and South America would appreciate your publishing this table in the form which has been found so convenient.

As will be noticed, weights are shown from 1 to 99 lb., and by simply changing the decimal point any amount can be figured. A few examples are also given on the table as guides to its use. Decimals are carried out to the last figure, so that large amounts will be as accurate as possible when this table is put in use.

CONVERTING POUNDS INTO KILOGRAMS

	Pounds									
Pounds	0	1	2	3	4	5	6	7	8	9
0	0	0.4536	0.9072	1.3608	1.8144	2.268	2.7216	3.1752	3.6288	4.0824
10	4.536	4.9896	5.4432	5.8968	6.3504	6.804	7.2576	7.7112	8.1648	8.6184
20	9.072	9.5256	9.9792	10.4328	10.8864	11.34	11.7936	12.2472	12.7008	13.1544
30	13.608	14.0616	14.5152	14.9668	15.4224	15.876	16.3296	16.7832	17.2368	17.6904
40	18.144	18.5976	19.0512	19.5048	19.9584	20.412	20.8656	21.3192	21.7728	22.2264
50	22.68	23.1336	23.5872	24.0408	24.4944	24.948	25.4016	25.8552	26.3088	26.7624
60	27.216	27.6696	28.1232	28.5768	29.0304	29.484	29.9376	30.3912	30.8448	31.2984
70	31.752	32.2056	32.6592	33.1128	33.5664	34.02	34.4736	34.9272	35.3808	35.8344
80	36.288	36.7416	37.1952	37.6488	38.1024	38.556	39.0096	39.4632	39.9168	40.3704
90	40.824	41.2776	41.7312	42.1848	42.6384	43.092	43.5456	43.9992	44.4528	44.9064

Examples:

1 lb. = 0.4536 kg.
10 lb. = 4.536 kg.
100 lb. = 45.36 kg.

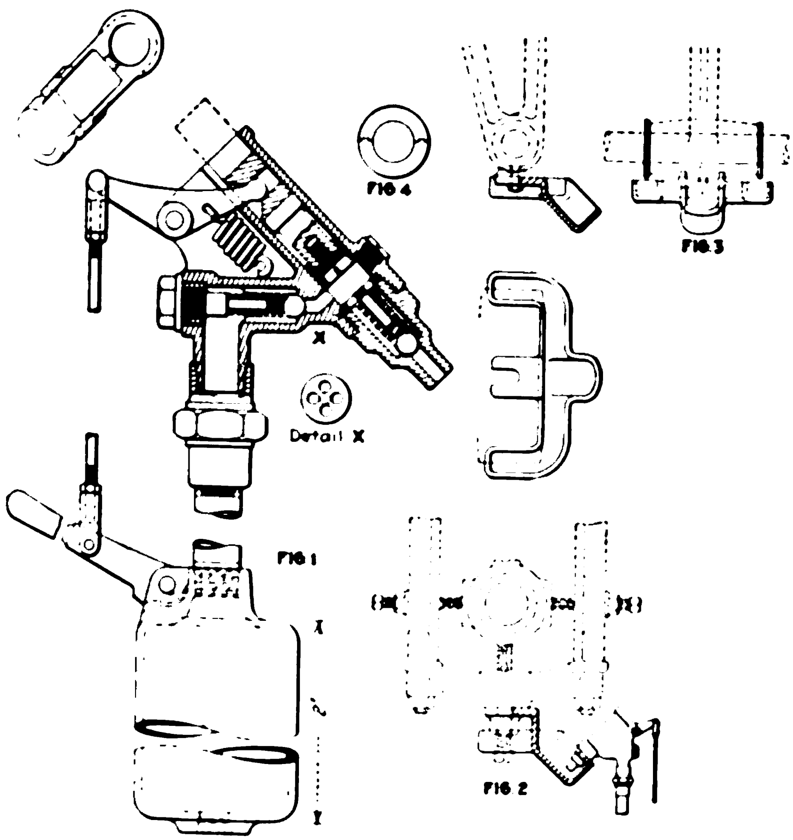
237 lb. to kg.:
200 lb. = 90.72 kg.
37 lb. = 16.78 kg.
237 lb. = 107.5 kg.

6,784 lb. to kg.:
6,700 lb. = 3,039.12 kg.
84 lb. = 38.10 kg.
6,784 lb. = 3,077.22 kg.

Letters from Practical Men

Oil Drip and Hand Pump

Factories with line and countershaft bearings experience considerable difficulty in caring for the dripping oil. Where roller or self-oiling bearings are in use, there is generally very little trouble. Some shaft hangers are furnished with a small drip cup at each end of the bearing, others with a single cup long enough to take the drip from both ends; but these usually are so small and shallow that they are practically of very little use.



DETAILS OF IMPROVED OIL DRIP AND HAND PUMP

In many instances they are replaced by large tin cups, which are difficult to attach and unsightly. The floor under plain bearings is generally oil soaked, and machines located under them get covered with oil. This condition, of course, applies to bearings that do not get regular attention. It is seldom that they are cared for until absolutely necessary.

When pulleys are located so that the hubs are in contact with the bearings, oil works over the hubs, arms and rims and finally saturates the belt. Oily belts form a good proportion of the troubles of the shop and are not only a source of expense, but sometimes the occasion of serious delays.

Bearings with plain ends, as shown in Fig. 3, allow the oil to work back and drip from the center. Some now in use, however, have a groove on the under side near the ends, forming lips from which the oil drips into the cups proper. The pulley hubs are plain, and the oil works over them as described; but if they were furnished with a groove near the end of the hub, it would prevent this trouble. This remark refers to pulleys with solid hubs. For pulleys with split hubs the only satisfactory solution is to use an oil collar.

The split oil collars, Fig. 4, used in connection with the proposed drip guards in Figs. 2 and 3 will prevent the oil from working onto the hubs of pulleys. It drips from the collars into the guards and collects in the central well.

The collars are made of cast iron and are not finished, except the sides, which are ground, the dovetails being cast so that they will engage their slots without machine work and with a minimum of hand labor. A shallow groove can be chipped in the end of the bearing to engage a pin, not shown, driven into one-half of the oil collar, to prevent turning where high speed would be likely to throw the oil. The collars, being in halves and $\frac{3}{32}$ in. thick, can be easily applied to the shaft, and the alignment of the pulleys can be readily adjusted.

The oil drip guards, Figs. 2 and 3, can be made to suit different lengths of bearings by having pattern-boarded and loose pieces to fit between the well and the ends. The lug for the supporting guard is made loose and can be adapted to line or countershaft bearings, as may be required. The central well collects the oil from both ends of the bearing, and the oil is removed by using the hand pump, shown in Fig. 1, operated from the floor. This method obviates the necessity of the oiler's carrying a ladder around the shop.

The pump is very cheaply made, easily cleaned, with ball valves of limited travel and a plunger with double cup leathers. It is operated by pressing down on the handle on the receiver, when the spring attached to the plunger lever returns the handle to the position shown in Fig. 1.

The receiver has a pet-cock in the bottom and can be easily emptied. A small hole should be drilled in the top of the receiver for a vent. The pump is comparatively light, so that it is easily carried. The operator can empty a large number of drips in a very short time. A pump and a few of these guards have been made, and this method of caring for oil drips has proved very satisfactory.

A. D. Vance.

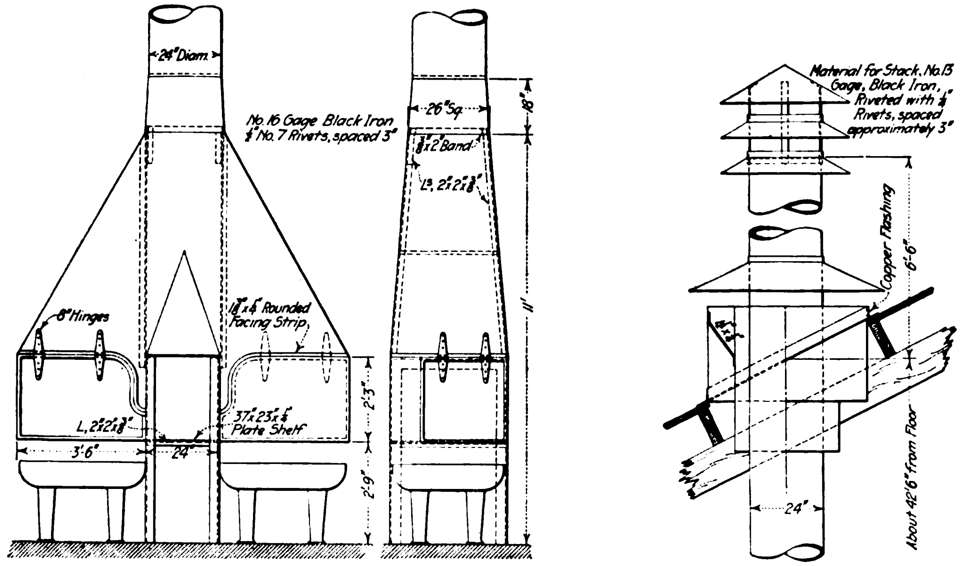
Warren, Ohio.

Canopy for Removing Gases from Blacksmith Fires

The illustration shows a canopy for forges in smith shops. It was developed on account of the state inspector's taking exception to the amount of gas in the blacksmith shop. The arrangement of the forges is shown in Fig. 1.

The canopy supports are two inverted V's made of 3/8x3x3½-in. angle iron. Two handy shelves for tools are made possible by this construction, as can be seen.

Each blacksmith has an opening, or space from the forge up to a point about 5 ft. above the floor. The back, or far side, directly at the back of his fire, is closed by the plate, which hangs on hinges but can be swung up if desired. A 27x28-in. plate hangs down also at the blacksmith's right when facing the fire, and can be swung up out of the way when necessary. The canopies have worked very nicely and removed the gases to a considerable extent.



FIGS. 1 AND 2. CANOPY FOR REMOVING GASES FROM BLACKSMITH FIRES

A canopy is made from No. 16 black iron. It combines a square and then a round section 24 in. in diameter.

Fig. 2 shows the outlet above the roof, with the thimble to prevent the roof's catching fire, and also the hood and ventilators above. Copper flashing is used to make a rainproof fit.

Renovo, Penn.

Engineering Journals and the Masses

Means of communication are now so perfect and the domain of engineering knowledge has recently been so greatly enlarged that technical engineering periodicals are finding an ever larger sphere of influence and are filling an ever larger need. Not only do they describe and illustrate discoveries and processes, sometimes even before the latter are perfected, but they provide that medium of popular discussion and that "theater of the thinker" wherein the crude facts of everyday engineering practice may be sifted into a record of all that is most worthy to enter permanently into the solid technical literature of the country.

This country is busier now than it has ever been in its history, and the masses have neither the time nor the means to purchase books or patronize libraries. Ten dollars' worth of engineering periodicals places every working family in direct touch with the great sources of current intelligence and practice. Moreover, it is certainly better to distribute the interest in mechanical and engineering progress throughout the year than to serve it to the public in the heavier book form, to be devoured *en masse*.

Indeed, in no other form than the magazine can all the scientific labor of the world be gathered up and distributed so cheaply, and it finds ten readers where in book form it would one.

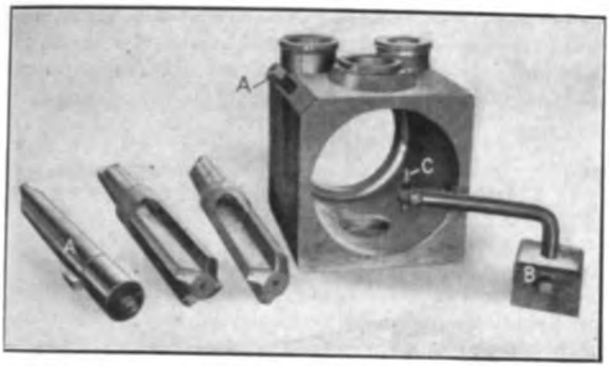
The present-day technical journal of America stands in the very front rank as an agent of progress and is demonstrably equal to any popular technical magazine in the world. I am naturally more familiar with this class of periodical literature than any other, and I make this statement without qualification or reservation. That its work has been proved to be good and that it is truly educating its readers are shown by the constant demand for a higher standard of excellence in this democratic form of literature.

R. D. GATEWOOD.

Philadelphia, Penn.

Boring Jig for Pistons

The illustration shows a jig used in machining the wristpin holes in pistons at the plant of A. B. Farquhar Co., Ltd., York, Penn. The piston is first turned and faced to the correct dimensions. It is then slid into the jig, being located by the shoulder shown at the rear. The setscrew A is tightened to hold the piston in position. The piston-pin holes are drilled and reamed, the tools



JIG FOR BORING PISTONS

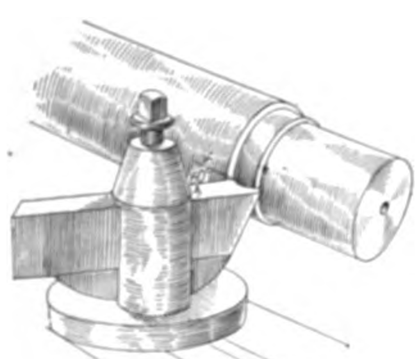
being guided through the bushings seen on top of the jig. The bar *A* is inserted in the jig, guided by the bushings, and the inside faces of the bosses are machined.

The height block *B* is used to test the machined surfaces, and the upper and lower bosses are tested by the two ends of the steel pin *C*. The height block can be slid into the open end of the piston with the facing bar still in position, thus enabling the operation to be performed quickly and conveniently. A. TOWLER.

New York City.

Turning Without Chatter

Grind up a tool of any standard high-speed stock, as shown, and set it at an angle of about 60 deg. so there will be no chatter. I find this method very



BEST WAY TO TAKE A FINISH CUT

successful on nickel-steel shafting, taking one cut instead of two, as formerly. This answers very well in our class of work. M. JACKER.

Stockton, Calif.

Table of Piston-Ring Data

The accompanying table is a collection of ring data that are complied with to a great extent in the machinery division of the United States navy yard, Boston, Mass. While these data are not official, they run very close to the average make of rings found in the commercial and naval engines of small caliper.

The standardizing of piston rings has not been given a great deal of publication, but this table is adaptable to ordinary snap rings that are to be rough-turned and bored, cut and drawn together, and finished to the diameter of the cylinder.

TABLE OF PISTON-RING DATA

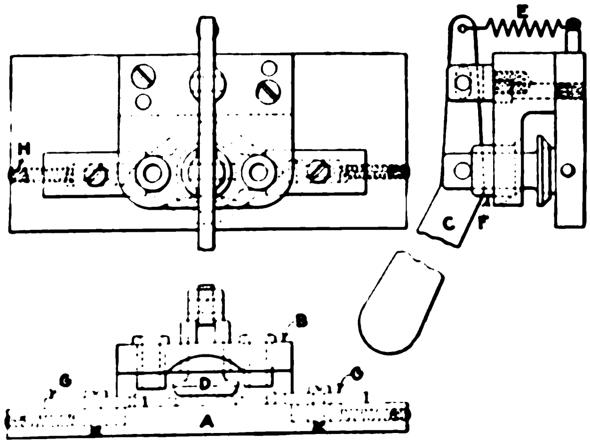
Diameter of Cylinder, In.	Rough-Turn Diameter of Ring, In.	Rough-Bore Diameter of Ring, In.	Amount to Cut Out, In.	Width of Ring, In.	Thickness of Ring, In.
2	2[illegible]	1[illegible]	[illegible]	[illegible]	[illegible]
3	3[illegible]	2[illegible]	[illegible]	[illegible]	[illegible]
4	4[illegible]	3[illegible]	[illegible]	[illegible]	[illegible]
5	5[illegible]	4[illegible]	[illegible]	[illegible]	[illegible]
6	6[illegible]	5[illegible]	[illegible]	[illegible]	[illegible]
7	7[illegible]	6[illegible]	[illegible]	[illegible]	[illegible]
8	8[illegible]	7[illegible]	[illegible]	[illegible]	[illegible]
9	9[illegible]	8[illegible]	[illegible]	[illegible]	[illegible]
10	10[illegible]	9[illegible]	[illegible]	[illegible]	[illegible]
12	12[illegible]	11[illegible]	[illegible]	[illegible]	[illegible]
14	14[illegible]	13[illegible]	[illegible]	[illegible]	[illegible]
16	16[illegible]	15[illegible]	[illegible]	[illegible]	[illegible]
18	18[illegible]	17[illegible]	[illegible]	[illegible]	[illegible]
20	20[illegible]	19[illegible]	1	[illegible]	[illegible]
22	22[illegible]	20[illegible]	1[illegible]	1	[illegible]
24	24[illegible]	22[illegible]	1[illegible]	1[illegible]	[illegible]
30	30[illegible]	28	1[illegible]	1[illegible]	[illegible]
36	36[illegible]	33[illegible]	2	1[illegible]	1[illegible]

While the data in the table will not conform to all classes of work, they will be found to cover the general requirements on gasoline and steam engines and will be of especial value and guidance to the machinist in whose hands the construction of rings is placed.

Winter Hill, Mass. N. I. MOSHER.

Drill Jig for Flanges

The illustration shows a drill jig for flanges, but it can be adapted to drill other parts of like description. The tool is made with a base plate *A*, on which the bushing plate *B* is fastened. The handle *C* carries the piece *D*, which is centered by the guide bushing *F*. When pres-



DRILL JIG FOR FLANGES

sure is taken off the centering piece *D*, it is raised by means of the spring *E*. The sliding V-blocks *G*, with suitable springs and adjusting screw *H*, locate the part to be drilled. A. ELTING.

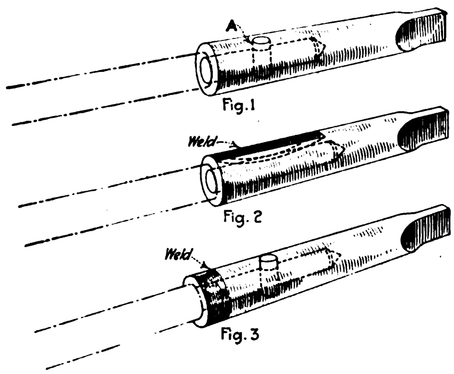
New York City.

Securing Loose Shanks on Adjustable Reamers

Reamer service in our plant is severe. We use adjustable inserted-blade reamers, with a nut at each end of the blades. The back nut must be put on from the driving end of the reamer and is smaller in diameter than the large end of the taper shank. It is therefore necessary for the taper shank to be made as a separate piece that is secured in place, after the nut is on. The manufacturer

uses a pin driven through the socket and shank, as illustrated in Fig. 1. This method is not a success, because the pins shear off at the point *A*.

We have remedied the trouble to our own satisfaction by welding with the electric arc, as shown in Figs. 2 and 3. Both ways are successful. It is probable that the mode shown in Fig. 3 would be better suited for the oxy-acetylene torch. The tool is somewhat distorted after



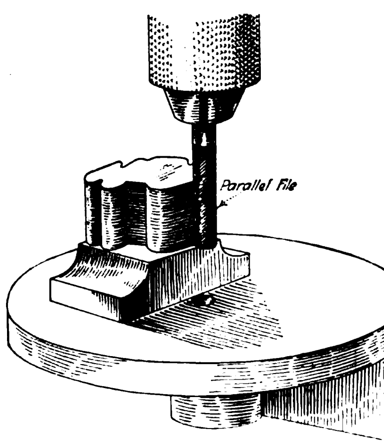
METHOD OF SECURING LOOSE SHANKS ON ADJUSTABLE RUNNERS

welding, but can be readily straightened between centers and the excess metal turned off. The reamer is then ready for use without danger of being back in the toolroom for repairs after reaming a few holes.

Mansfield, Ohio. R. A. WILLIAMSON.

Filing Punches in Drill Press

In fitting a punch to a die, the top of the punch is covered with a layer of solder about $\frac{1}{32}$ in. deep. The punch and die are put in the press, and an impression of the die is made on the solder on the end of the punch. This is placed in the miller and rough-



FILING PUNCHES IN THE DRILLING MACHINE

milled to shape. After the milling operation is finished, the solder is removed and a light shearing impression taken about $\frac{1}{32}$ in. deep on the punch. The work is then taken to the drilling machine and the punch filed to size. Round parallel files from $\frac{1}{16}$ to ½ in. in diameter can be obtained in any supply house.

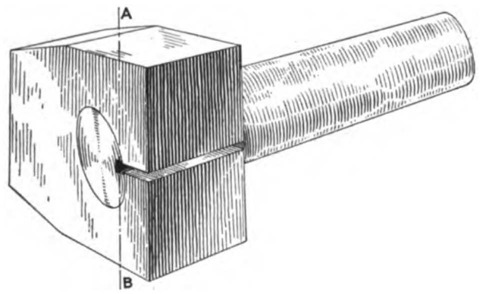
I have found this method much faster than the ordinary way of hand filing in the vise and also more accurate. It is of course of no use for female square corners. WILLIAM CUNNINGHAM.

Chicago, Ill.

Closing In Large Keyways

In a place where I worked a few years ago several hundred shafts were rejected because the keyways were cut a little too wide. They were to be a standard size to fit pulleys and keys furnished by another company, so it looked like replacing the whole lot.

As an experiment a block of machine steel, as shown, was carefully bored to fit the shaft and sawed through one side. The corners opposite the slotted side were



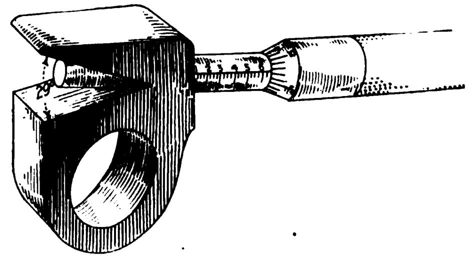
CLOSING IN LARGE KEYWAYS

beveled to center line. With the shaft inserted with the keyway at the saw slot, the hydraulic pressure was applied through the line *AB*. After a few trials the right pressure was found to be about 80 tons. This closed the keyway in just the right amount and changed the diameter of the shaft so little as to be negligible. The whole lot was treated this way and passed the inspector with flying colors. H. HOWARD.

Watertown, Mass.

Improvised Thread Gage

A tool had to be provided for gaging large thread tools. As a suitable vernier could not be obtained within the allowable time, the device shown in the illustration was made and met the requirements nicely.



A THREAD GAGE

The complete tool cost but one-half as much as a reliable thread-tool vernier. It is also convenient to handle and gives accurate readings, as 0.001-in. graduations on the micrometer head represent about 0.00025 in. on the width of the tool point. OLIVER MARTIN.

Chicago, Ill.

Discussion of Previous Question

How To Square the Heads of Bolts in a Lathe

On page 403 you show a stunt for squaring the heads of bolts in the lathe. Without being unduly critical, it would seem as if it were pretty crude in this day and generation—particularly for the "large number" mentioned. The accompanying illustrations will show what has been the usual practice in similar cases that have

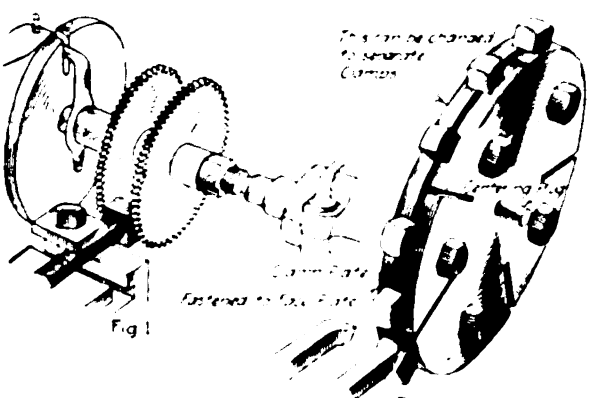


Fig. 1 Fig. 2

HOW TO SQUARE THE HEADS OF BOLTS IN A LATHE

come to my notice. The method shown in Fig. 1 is preferable, but if it were impossible to get a couple of saws, which is extremely unlikely, the scheme illustrated in Fig. 2—which is a lathe job pure and simple—is satisfactory. It would seem more desirable to go to the trouble of making fixtures as shown and then be able to turn out the bolts quicker and better than to bother with them singly.

Hartford, Conn. GEORGE R. RICHARDS.

Opportunity for Machine Tools in Holland

Upon reading Ludwig W. Schmidt's article on page 505 the initiated will agree to its truth on broad lines, as they will be able to credit divers assertions with their real value. For the would-be exporter who still lacks experience the article seems a bit too general.

That the exports of American machine tools to Holland have risen from an average of about $80,000 a year to nearly $200,000 is no reason for the American exporter to pat himself on the back. The credit belongs mainly to the alert managers of some big Dutch firms who opened offices in New York last year. Many Dutch merchants are constant readers of the *American Machinist* and carefully watch its advertising columns (which shows the quickest way to attract attention). The Consulate General of the Netherlands is also willing to give helpful hints to interested parties. However, do not bother these firms if there is no stock on hand for immediate sale. They are here with desks cleared for action, and at present they may be regarded as the only desirable mediums for war business. The question of these connections in time of peace will be discussed later.

Indications point to the fact that Holland will soon have to begin to buy again in larger quantities. As her previous sources will be dry for some time to come, the Dutch buyers will have to turn to the United States for supplies. The question at once arises as to how long the Dutch will turn to the United States, the anxious buyer being a phenomenon of abnormal times only.

If half the Commerce Reports are true, the American is yet a clumsy exporter at best. The American manufacturers should exercise great care in their efforts to retain their share of the trade with Holland, driven to them by the efforts of some Hollanders and by temporary circumstances. The American should study his foreign markets and get rid of the notions he has about educating such markets. It is he who must adapt himself to the situations abroad. The German is a past master in the act of adaptability. He will at the first opportunity gladly relieve the Dutch of looking for supplies abroad after the war.

It is said that the Dutch manufacturer is well able to see the value of the newer and speedier machines, but his conservative and saving disposition will not allow him to buy them. This, I believe, is the greatest fallacy of Mr. Schmidt's article. By analyzing this statement the would-be exporter will find a way to determine beforehand whether his articles are fit for the Dutch market or not.

The Dutch manufacturer is of neither a conservative nor a saving disposition; but he is not in business for fun, and usually he is found to be an apt and slow-going mathematician. Reckoning that labor in Holland can be had at 40 per cent. of the American price, a few calculations will give a scientific base for comparing American with foreign products and will indicate the limit beyond which no price may go, however superior the machine, and be acceptable to the Dutch market. The first thing the Dutch manufacturer is interested in is the *Rentabiliteits-rekening* (computation of interests); and where the speedier machine only comes up to the cheaper, old and trusted lathe, the human part of the outfit will have the preference.

Bearing in mind that business in Holland is slow and that success comes only to him who waits, the beginner will not have much difficulty in choosing one of the ways discussed herewith.

The method of direct correspondence and advertising being usually impracticable at such a distance, the first way to be considered is opening in Holland a branch office managed by a smart American salesman. Usually and wrongfully (referring to others outside the machinery line) he will settle in Utrecht, this being the center of gravity of the railway system. Amsterdam or Rotterdam, with their shipping facilities, though not so central, will prove to be more suitable. Their surroundings,

especially Rotterdam's, are substantial fields in themselves; and as Holland is only a small country, any big town is practically central.

After having started actual work, the salesman will find out that his profession, here much envied, is often looked down upon in Holland. After having traveled a few times to Euschedé or farther still on the same small errand, the outside courtesy of the unmovable Hollander, who seems to have unlimited supplies of time, will wear on the American. He will also notice that the big machinery importers are really big, even to American conceptions, and that they will not stand for any substantial outside rivals. Last, but not least, the field is limited, and it will be never more than a side line to any manufacturer.

A better way is to make common cause with one or more, if possible, of the big machine-tool jobbers. Though substantial profits are not excluded, it is a very haphazard way, the dealers having most of the trump cards. They usually have as many agencies on hand as they care to have—and at their own terms. They furnish the public in immediate need at their own price, seldom going beneath a fixed scale of profits. Their interest is sometimes, but more often not, that of the tool manufacturer. Such jobbing concerns are in the habit of answering one inquiry with several propositions by the different firms they represent. It is often amusing to an inquirer to receive bids on the same machine from different jobbers, the smaller firms often making far more acceptable offers, but as a rule they cannot deliver at once.

The bigger concerns back themselves with their beautiful, well-supplied machinery halls. Their methods are not beloved, but they can deliver the goods in a pinch; and the appreciation has to be shown in hard cash.

These practices are too well-known to the American manufacturer to require further discussion. The German method of securing continuous profits out of a small market at hardly any expense will need all the imagination of the American reader who has not traveled abroad. It might be remarked that the Hollander differs more from the business man of the United States than does our Brazilian brother.

The American question, "Who is he, anyway?" may be often fully answered in dollars and cents. But in Holland, schooling, breeding, family and social standing are the important factors. The money the Hollander is really interested in is his own. Things American grow overnight, but everything in Holland is the product of slow cultivation, and business connections are the same. The Germans and several English firms situated too far from the Dutch border to do their own traveling foster these connections by means of local agents.

An advertisement in the *Telegraaf, Het Nieuws van den Dag* or the *Nieuwe Rotterdamsche Courant* for an agent, preferably a gentleman commanding sufficient spare time, will bring forth instructors of technical colleges, city engineers and inspectors who gladly will spend their surplus of energy in building up their own and part of your business. They are men of small means, but highly respected. While selling, they are able and willing to give appreciated advice. One machine sells another; and where the American is far more liberal than the German or English competitor, it is easy for him to make his man sell that first machine.

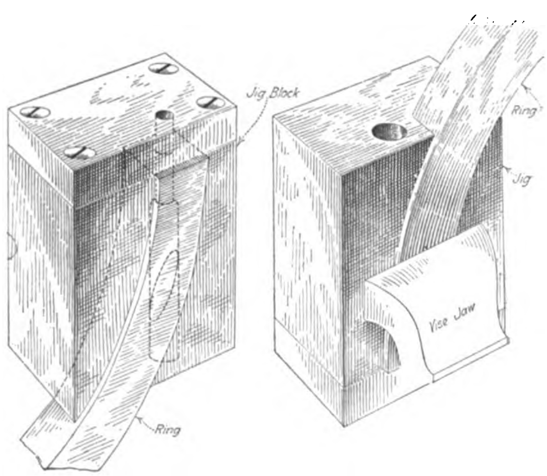
The German or Englishman seldom supplies his agent with anything else than the catalogs on hand. Printing expenses in Holland are low, and by presenting a good Dutch edition to the agent and a machine for demonstration it will not be hard to beat the opponents at their own game. Such machinery can be intrusted without fear. Though Dutch capital is small compared with the amounts here, it is as good; and so it is always safe to allow credit. Social conditions do not tolerate any serious dishonesty. The American has also to bear in mind that he must not play any tricks on his small representatives, if things do not seem to move quick enough. Dutch law by no means protects the richer man; and it does not take much money in Holland to put up a legal fight, if wronged. These agencies are usually given for a term of five years and often exclusively for Holland and its colonies. If the "main-representative," as the agent is styled, comes half up to expectations, German firms usually give him another term and make him win.

The big merchants in Holland know that they cannot beat the small machinery agents of their market. When an American tool manufacturer has not been successful with the big firms, there is no reason why he should not put his foot in the Dutch stirrup, by pushing it steadily in that systematic, inexpensive, penetrating way.

Brooklyn, N. Y. JAN SPAANDER.

Oil-Ring Difficulties

In reply to the article by Harold E. Greene, on page 513, regarding difficulties in oil-ring manufacture, I will try to explain how I avoided these troubles in the same kind of shopwork. I recall that one of the most important things in a shop is to have all machines in



THE RING AND THE JIG

good working order. This practice would have prevented the loose spindle of the press. Having an order for some rings somewhat similar to those described by Mr. Greene, I used the following method of machining: First, all the rings were turned the proper size, then cut in the miller. The holes for the bolts were drilled after a jig had been made, as shown in the sketch. This

jig was made in a short time from a piece of close-grained cast iron.

Drilling the holes in this manner saved the extra lathework required to make the ferrules that Mr. Greene secured in the large hole to hold the bolt head. It also overcame the necessity for making counterboring tools, as the drill was ground so that it acted as a countersink. A countersinking operation was also avoided. Of course, the body hole was drilled last, which meant changing drills, but this was a small matter compared with doing the work the other way.

All holes were run to proper depth by setting the stop on the spindle of the press. Counterbored holes for the heads of bolts were put on only one end of the rings, so that the rings would be balanced very closely. The holes for tapping were drilled only deep enough to tap properly, as this left the ring so much stronger than drilling them through. Distance pieces the thickness of the milling cutter that had been used to saw them were made and inserted to make the rings true. By manufacturing all rings in this way it was found that they were interchangeable.

I should like to have Mr. Greene's views on my method, as I do not want him to think that I am too critical.

New York City. F. C. Wolf.

Grinding Die-Setting Pins

I notice that Mr. Greenleaf, on page 691, comments on the subject of die-setting pins, or what are often called pillars. Hardened and ground pillars running in hardened and ground bushings, while they may be the most expensive, will surely give the best results, especially if used on a die that is built for cutting thin stock. The punch for such a die is made a good fit to the die; therefore, pillars that fit well and wear well are desirable. However, in nine shops out of ten the practice is to use hardened and ground pins running in a reamed hole in the punch holder.

Mr. Greenleaf speaks of squaring a plate to the drill-press spindle by means of a sweep and indicator. This is the method employed to get the best results possible on the drill press; and if the spindle of the press is in good condition, a plate may be squared and a hole drilled and reamed fairly square. A drill-press spindle that is free from play is a rarity, however. If there is shake in the spindle, it is impossible to square it to anything and quite as impossible to drill and ream a hole squarely.

The best method of machining the holes for the pillars of a pillar die is to clamp the shoe and punch holder to an angle plate in the miller, then drill, bore with boring bar and ream all the holes without disturbing the set-up. When set up on the miller, the job should be squared to the spindle by means of sweep and indicator.

Newark, N. J. Gustave A. Remacle.

Clearing Chips from Deep Holes

The article of C. C. Lynde, on page 776, is interesting and helpful, doing an old thing in a little different way.

It has been my practice either to magnetize the drill or take a piece of tool-holder steel of the tungsten variety and magnetize it for the same purpose. An advantage in using the kind of steel mentioned is that it holds the magnetism much better than does ordinary carbon steel. If the drills are of high speed, it is more valuable for the purpose. It is true that the chips will cling to the drill; but that is not a serious objection, as they can be removed by the hand or a brush while the drill is in motion.

A rather amusing incident in dealing with the property of magnetism was brought to my attention by a glass manufacturer some time ago. It seems that a rather large piece of steel or iron had fallen into the glass furnace and its presence was causing trouble, so the man took the matter up with an electric company, which suggested that he use an electromagnet for removing the piece.

He acted upon the advice, and his feelings when he found that it was of no avail can be imagined.

When it was explained to him that the magnetic properties of iron are not present when the temperature is as high as in a glass furnace he understood what was wrong. E. T. Strong.

Columbus, Ohio.

What's the Matter with Our Methods of Threading?

The article by P. W. Abbott on page 173 of Vol. 44 of the *American Machinist* contains some valuable hints, but there are several points to which exceptions can be taken.

The first statement, that "accurate work cannot be done with the commercial taps and dies sold by the tap and die manufacturers at the present time," can be seriously questioned. Perhaps Mr. Abbott is not in touch with the latest product of the tap and die manufacturers, as the writer personally knows of several concerns that are producing taps and dies well within the limits that Mr. Abbott considers necessary for good work.

The statement that round adjustable or button dies are the most economical has been proved to be wrong by several firms that are constantly testing the products of a large number of screw machines.

In commercial threading, the button die was the first step and met with indifferent success; then came the spring die, which was some improvement over the button die, and the acorn die. Button dies can be sharpened only by using special emery wheels, which are small and easily fractured. This operation requires a great amount of time and care. The spring die can be sharpened easily, but the amount of surface to be ground is large. The acorn die presents but little surface, which can be easily and quickly ground.

There are cases where it pays to use opening die heads, particularly on long threaded parts. More pieces are spoiled by backing a die off the work than in any other way. There are two questions that cannot be decided in an off-hand manner—the matter of using either a solid or an opening die and whether a roughing and finishing cut or a single cut may be necessary. There are a number of considerations that enter into the problem—namely, the make of machine, the length of the thread, the nature of the stock, the speed at which the machine can be run (both forward and reverse) and the nature of the lubricant.

Threads can be cut faster with an opening die, because there is no reversing; so that while there are instances

where it may take more care and time to get an opening die head to working properly than it does to use a solid die, the increased production will more than repay the time spent in setting up.

Mr. Abbott speaks of inaccuracy of threads being due to the wear of die heads, yet he overlooks the fact that

7/8	14	139.0	34.0	0 6407
1	14	130.0	34.0	0 6412

* These tables are figured on the theory that the amount of metal removed per minute should be the same for all sizes; 17/32 in.-20 U.S.F. threaded at 500 r.p.m., which is 69.5 lin.ft. per min. actual practice at Wells Brothers Co. on tap-wrench handles, is used as a basis. The material is screw stock.

in an opening die with the lands supported directly over the cutting edges and with a bearing at least four times the length of the thread there is little chance for wear. The die should be made with a hob that is just as close to size—pitch diameter, root diameter and lead—as is necessary in the screw to be produced. Having the hob oversize or undersize starts the whole trouble, particularly in the lead. If the screws wanted must be within ±0.001 in. or ±0.002 in. in lead and pitch diameter, then the hobs for making the dies must be within these limits.

Regarding lead, Mr. Abbott states: "There is just one thing that affects lead, and that is the tools doing the thread cutting. If the taps, dies or chasers have the correct lead, the work will also be correct." There are a number of other reasons why a die will not cut correct lead, and among them may be mentioned: Different kinds and grades of material, dull dies, uneven relieving, broken teeth in the die, different lubricants, different cutting speeds, a pull or a push on the die, a burr at the back edge of the lands, shortening or lengthening the chamfer, more or less hook on the lands, cutting a larger or smaller pitch diameter than that of the hob which made the die, cutting oversize or undersize stock, variations in diameter, crooked stock, variation of cutting speeds, nonalignment of machine.

The suggestion by Mr. Abbott that there should be a lead-testing fixture in every department is excellent. One that has given good satisfaction and is inexpensive is shown in the latest catalog of a leading tap and die manufacturer.

Taps ought not to be straightened after hardening. They should come out of the hardening and tempering baths within the prescribed limits or else be rejected. Time that is spent in trying to straighten such taps is thrown away. The U.S.S. taps now made by the best manufacturers are large enough on the outside diameter so that there is no interference with the outside diameter of screws, and the hobs for the dies are made so that the contact of the screw with the tapped hole must come on the pitch diameter. This is well shown on the line drawing of a ½-13 U.S.S. screw and tapped hole. It is assumed that the screw will be made 0.002 in. under basic on the outside and the tap at least 0.002 in. over basic on the outside. The hole is drilled to give 75 per cent. depth of thread.

The old-fashioned way of each manufacturing concern having a standard of its own, so that its customers will be obliged to buy all repair parts from one source, has nearly gone by, so that it seems to the writer that there is no need for the so-called Cadillac form of thread.

There is no doubt that the size of hole to be tapped depends somewhat upon the size of drill used, and Table 1 gives correct sizes of drills that will give 75 per cent. depth of thread, which gives an ample margin of safety (practically 2 to 1) and is economical in tapping. Table 2 gives threading speeds for opening dies. It is based on the actual practice of Wells Brothers Co., Greenfield, Mass., where tap-wrench handles are threaded with 17/32 taps, 20 U.S.F. thread at 500 r.p.m., which gives 69.5 lin.ft. cutting speed. Another size, ⅝ in.-20, was run at 80 ft. and 1 in.-16 at 62 ft. per min.

Greenfield, Mass. CHARLES E. SWART.

Improvised Taper Boring Bar

I am greatly interested in the article by Howard Brady, on page 320. No doubt, the bar described would do the job if light cuts were taken and the compound slide rest had the screw taken out, which would leave the rest free to move according to the taper of the bar. Otherwise, I am afraid that if the turner carried out the instructions as printed, "Put the feed on and sit down," he would find some trouble. R. L. HASELGROVE.

Amersham Common, England.

Fairness in Hiring Men

Firms that in hiring men use the methods described on page 779 have evidently much to learn in managing a business. The best men will not submit to any such third-degree treatment except in cases of dire necessity and then only until they can obtain work in more desirable shops. Managers who really understand modern methods of securing and retaining employees know that such treatment does not pay; they have found that a man-to-man attitude—an exchange of information regarding points which both need to know—secures the best men and the best work.

The old czar-like type of employing agent has no place in modern establishments. The largest and best plants today understand this fully, and men seeking employment receive courteous treatment from office boys and clerks. It is just as easy in the first place and, secondly, it gives a new workman a much better impression of the shop he is to work in. This feeling is reflected in his work and in his whole attitude toward his employer.

Aside from all other phases of the question—and there are many—the cost of changing men runs up into thousands of dollars per year for any large firm. Realizing this fact, wise employers make every legitimate effort to keep a man even after he has not succeeded in his first job. Some shops try a man on at least three different kinds of work before finally letting him go as unsatisfactory.

These modern firms are also learning to cut out as much of the red tape of employment records as possible. Only essential questions are asked, and all proper inquiries regarding the job or the shop are fully answered.

The keeping of records of unsuccessful applicants is an involved point. If kept solely for future reference to save time and used only in a legitimate manner, there seems little harm in it. If used to prevent employment there or elsewhere because of a fancied dislike or for personal characteristics, it might easily work harm and injustice. When hiring men, as in so many other of life's activities, it is a great gift to be able to put yourself in the other man's place and view the situation from his standpoint. By remembering that the applicant selling his services is no more an object of charity than you are when you sell your product it is perhaps easier to get a more rational perspective on the whole transaction. There are at least two sides to this matter, as to other questions, and it is well to study all sides.

Ways of Saving Shells

Numerous comments have called the attention of the readers of the *American Machinist* to the foolish demands of ordnance officials representing various governments for which shells are now being made in the United States. Another phase of the subject that requires just plain commonsense (and in these matters commonsense seems to be the most uncommon sense) is the saving of good shells that are condemned to the scrap pile. There are perhaps half a million shells that would now be at the front, where they are wanted, were it not for a lot of foolish regulations imposed in many cases by men who have no idea what conditions a shell must fill.

We do not mean that shells defective in material, too light in weight or otherwise impossible to make serviceable should be passed as serviceable, but we do most emphatically mean that all shells that can be made serviceable at a price which will show a saving over replacing them with new shells should be made to pass.

More shells are condemned because they are light in weight than for any other one reason. There are several methods of increasing the weights of shells without in any way detracting from their serviceability. In Canada the copper driving band is closed cold into the driving-band groove. If such shells be light in weight—as much as 5 drams in the case of the 18-pounder and 2 oz. in the case of the 4.5-in.—they can be brought to weight by using the simple expedient of heating a new rough copper driving band to as high a heat as the copper will stand and, while still hot, pressing it under normal pressure into the driving-band groove. The weight can also be increased by subjecting the cold copper to greater pressure in the banding press. There is, however, some danger of injuring the shell when this is done, so it is just as well to avoid increasing the pressure. We have seen shells, the bands of which were pressed at high pressure, with the bases cracked entirely around so that they fell away when the shell was removed from the banding press. Repeated cold pressing at the regular pressure (about 1,200 lb.) will without injury increase the weight of a shell.

The weight of shells can be increased by compressing the metal in the base plates. This is done under the steam hammer, before the base plates are finished. The weights of shells can also be materially increased by extra coats of varnish in the inside. The weight that can be made up in this way depends on the size of the shell and the number of coats given.

Instructions given to some government inspectors preclude the heating of the copper band just before pressing it on. Why, is not apparent, for driving bands are heated red hot before pressing in the United States arsenal at Frankford, Penn., and even in Woolwich itself driving bands are heated before pressing. In any case the copper driving bands are heated red hot to anneal them before they are shipped from the copper mill where they are made. The only difference, therefore, would be the shrinkage stresses in the copper band after cooling on the body of the shell. This would merely give it a firmer grip on the shell body and would only amount to enough to reach the yield point of the copper. There might possibly be some difference in the hardness of the hot and cold pressed bands. If there were, would it be sufficient to cause any trouble?

Many shells are condemned when practically all the work is done on them, because the bases are small in diameter. We refer to that part of the shell below the copper driving band. The only part of the shell that

bears on the barrel of the gun is the copper driving band. The base of the shell should not and does not bear on it.

In the case of the 3.3-in. high-explosive shell the base is 0.01 in. less in diameter than the bore of the gun for the high size and 0.02 in. for the low size. The tolerance here then is 0.01 in. Any shell that is below 3.28 in. in diameter on the base is rejected. This seems to be a foolish requirement. Of course, where articles are made to limits, the limits once established should be adhered to; but there often are ways in which pieces can be made to conform to arbitrary requirements and still be serviceable.

Work that is too small can be increased in size. This is true of the bases of shells. The base of the shell acts to a great extent as a gas check and not in the capacity of a bearing. If a small base can be brought to sufficient size to act as an efficient gas check, the desired end has been accomplished. With shells that are not too far under size, if a roller with sharp V-grooves of about $\frac{1}{32}$-in. pitch running round it be pressed radially against the base while the shell revolves in a lathe, the metal, displaced by the points of the sharp V-ridges of the roller, rises up above the surface and increases the diameter of the base so that it will fulfill its function as a gas check. When the shell is painted, the insignificant grooves are filled by the paint, and for actual use the shell is just as good as one accurately made to standard sizes.

Large numbers of shells have been condemned because the fuse-hole thread is too large and an equally large number because the thread is rough and imperfect in places. The tolerance here is 0.006 in.—large as viewed by the manufacturer accustomed to interchangeable work. In spite of that there are a number of shells with threads which will not pass inspection because they are too large. These shells are scrapped. There is no reason for this condemnation as the nose of the shell can easily and cheaply be closed in cold in a die, so that the thread can be retapped and pass inspection. Shells in which the threads are not too rough or broken can be salvaged in the same way by closing the nose and retapping. Many of the shells in which the thread for the fuse has failed to pass inspection would be passed if the inspectors were mechanics and allowed to use a mechanic's judgment.

We appreciate that it is not always possible to get mechanics for inspection work, but the men higher up in the inspection department of the government should not only be intelligent, but should be mechanics. It would then be a simple matter to lay aside such shells as fail to pass the under-inspectors and from time to time have them surveyed by inspectors who know the meaning of the term "good enough." These over-inspectors should be kept posted on the various methods by which shells that otherwise would be scrapped could be saved. It should be a part of their duties to inform manufacturers of all new developments in the art of saving shells.

Co-operation Between Consuls and Technical Press

On page 785 the *American Machinist* referred to the wide variety of information needed by American manufacturers in order that they may successfully hold foreign markets. To furnish this information, the United States Consular Service should canvass manufacturers at home and obtain from them lists covering the information they need in their particular lines. With this in hand, the Washington authorities could print blank forms intelligently, asking for this information and send these blanks to the various consulates. The consulates would then require the services of well-paid investigators whose duty it should be to get this specific information and, having once obtained it, to keep it up to date as market changes took place.

There are about 260 different varieties of manufacturing industries in the United States, each of which requires approximately the same kind of data. If the Government will furnish American manufacturers with really reliable and practical information, the work will be of tremendous importance.

In ordinary times our exports, or sales to foreign countries, amount to about 2,400 million dollars yearly.

The world's imports, or purchases, are in round numbers 20,000 million dollars. A substantial increase in our foreign exports should be easily attained if we act promptly and intelligently. The present increase in our exports is partly made up of articles sold at largely increased prices and war munitions. Both of these exports will of course cease when the war ends.

As a small item of assistance the various branch bureaus connected with the Consular Service in the United States should employ translators for all the foreign languages and thus enable an American manufacturer to answer inquiries intelligently in the language of the inquirer.

The *American Machinist* for many years has sent copies of its issues to the principal consulates in all parts of the world, since it has always believed that they are in close touch with the foreign consumer. As publishers of technical journals we are of course mainly interested in putting our own product before worth-while readers and obtaining their subscriptions. Possibly this hints at one field in which the Consular Service can aid by giving helpful suggestions. They will be gratefully received if offered.

It is doubtful if even American business men and manufacturers fully appreciate the gravity of the ocean-freight situation. To consider our trade relations with South America only: Prior to the war, freight rates to Buenos Aires, Argentina, were about $4 per ton. Recent rates have actually reached $40 to $50 per ton, varying with the commodity.

The average purchase price of a freight steamer before the war was about $50 per ton capacity. So the freight charges for a single 30-day voyage are now equal to the cost of the vessel.

The trade routes to South America and everywhere else must be kept open. Immediate action of some kind is necessary. It is probable that before these comments are printed the House of Representatives will have passed the bill to establish Government owned or controlled steamship lines. The Senate will then become the battleground and that body the one upon which Americans must exert pressure.

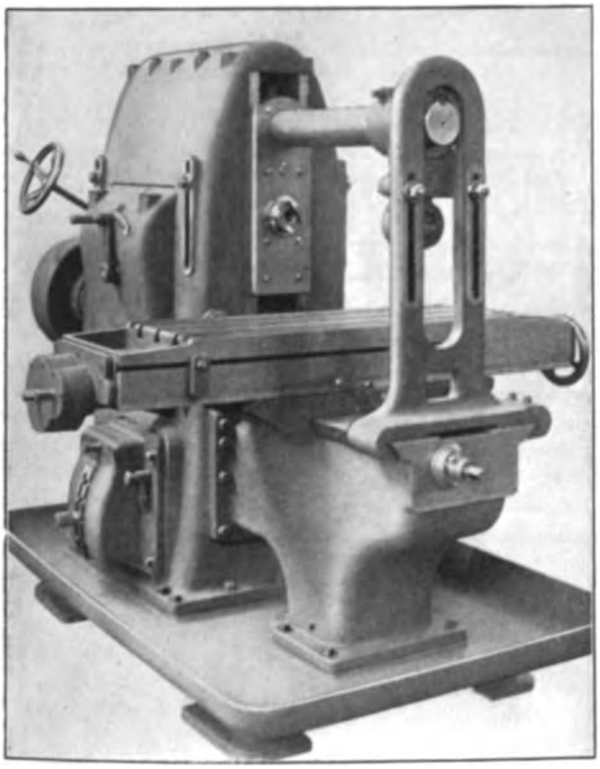
The situation is so critical that every seaworthy vessel within our jurisdiction should be utilized at once. Naval colliers, army transports, all other usable Government vessels and coastwise steamers whose cargoes can be handled by the railroads—all these should be employed immediately in American foreign trade.

Shop Equipment News

Manufacturing Miller

In the design and construction of the manufacturing miller shown it was the aim to make the height and load-supporting features of the table particularly rigid and constant, and to maintain the open-side principle of the knee-type machine.

The column is of heavy box-section design. The guides are four separate box sections. The front-head guides are finished on their inner edge, forming a narrow guide for the spindle head, with a ratio of width to length of



MANUFACTURING MILLER OF LINCOLN TYPE

Vertical range of spindle above table—high position—11¼ in.; low, 1¼ in., hand adjustment and dial graduated to 0.001 in.; table width, 13 in., table adjustment in line with spindle, 12 in.; spindle, 3¼ in., 5-hp. motor height of column, 69 in.; floor space, 65x65 in., weight, 4,200 lb

spindle head of 5 to 1. Steel gears are used throughout the machine, the driving gears being of spur form.

When a countershaft is used, the machine is driven through a three-step cone, and a wide variety of spindle speeds is available. Back-gear ratios of 5.9 to 1 and 2.8 to 1 are also provided.

In the operation of the table a lower splined shaft runs direct from an inner-feed bearing. Since the feed-gear box is driven by a chain adjustment is provided to take up the slack owing to wear. The feed gear meshing with the splined shaft rocks around the splined-shaft gear and allows ½ in. vertical adjustment of the feed-gear box.

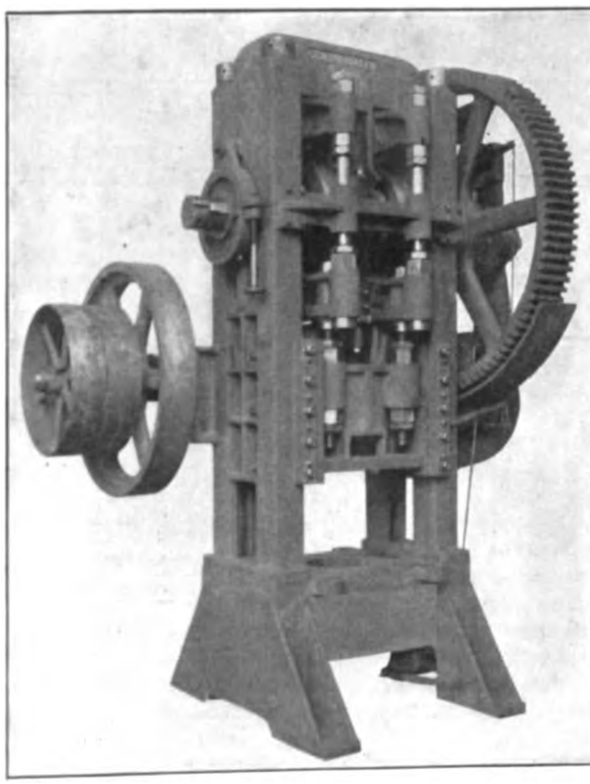
The table screw is of extra-large diameter, is splined for two keys and driven by a reversible clutch. The clutch is so arranged that the direction of the feed is against the driving clutch. The table is constructed on the narrow-guide principle. The feed trip is of the lever type, placed at the center and front of the table. The start, stop and reverse are made with one lever, which operates a push-pin that must be pushed in before the table feed directions can be reversed.

The feed box is of the apron type, cast in one piece. The gear system is of tumbler-gear design. The feed changes, of which there are eight, are obtained through two levers.

The machine is made in a number of sizes and represents a recent development of the National Transit Pump and Machine Co., Oil City, Penn.

General-Purpose Press

This machine was designed for an all-round blanking or drawing press. The frame has large openings in the side columns, which are a great convenience at times.



GENERAL-PURPOSE PRESS

Die space, 14 in. from bottom of outer slide to bed; from bottom of inner slide to bed, 15 in.; stroke, outer slide, 4 in.; inner slide, 8 in.; ram adjustment, 4 in.; will draw and lift out a shell 3½ in. deep; shaft, 6½-in. diameter in bearings and 7½-in. on crankpin, gear, 70-in. pitch diameter and 8-in. face; blank-holder rods, 2½ in. in diameter; height of press, about 12 ft.; floor space, 4x6 ft.; weight, about 22,000 lb.

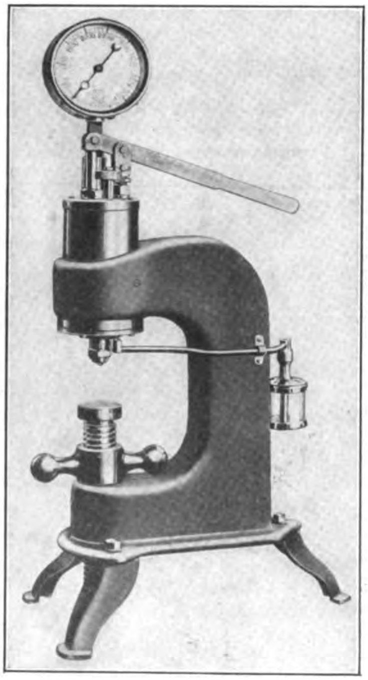
The frame is a four-piece tie-rod construction, held together by four steel rods shrunk into position. The frame is in sections, tongued and grooved at the joints, and may

be taken apart. The rods that operate the blank holder may be removed without disturbing the other parts. They pass through guide brackets that keep them in perfect alignment. There are two large disks on the shaft with bearings on the yoke above to take the thrust. The yokes covering the cam rolls have oil pockets and felt wipers. A consolidated jaw clutch is provided, but a friction clutch may be had if desired. The gear is lubricated from the end of the shaft in addition to oil cups. Ample adjustment is provided throughout for wear.

The press is made by the Consolidated Press Co., Hastings, Mich.

Brinell Hydraulic Hardness-Testing Machine

In the development of the instrument shown it was the purpose of the Pittsburgh Instrument and Machine Co., Pittsburgh, Penn., to provide a portable Brinell



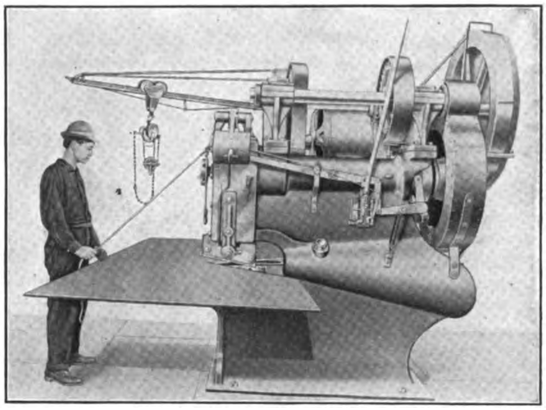
HARDNESS-TESTING INSTRUMENT

hardness-testing machine operated on the hydraulic principle.

The Brinell principle is so well known that the illustration does not require any explanation.

Pneumatic Punch or Shear Trip

This device is intended for use in punching or shearing large sheets, where it is impossible for the operator to reach the regular trip. A small air cylinder is bolted to the side of the press frame, and the piston is connected by levers to the trip lever. The piston action is controlled by a balance valve that throws the machine into motion, while a spring connected to the other end of the valve returns the piston and stops the machine, so that one pull on the tripping cord held by the operator has the same effect as one pressure on the tripping treadle. The device is easily attached and operated from the shop air line.



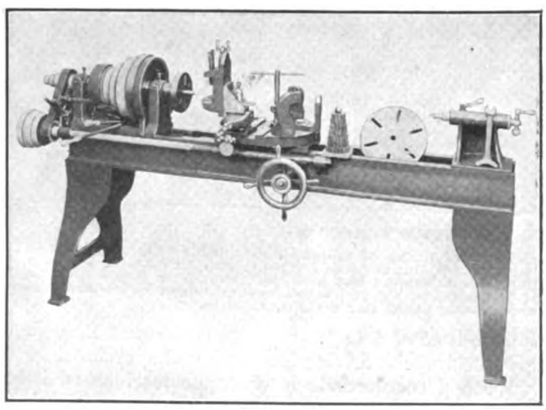
PNEUMATIC PUNCH OR SHEAR TRIP

When necessary, the operator may work the cord with his foot, leaving both hands free to handle the sheet.

This device is made by the Baird Pneumatic Tool Co., Topeka, Kan.

Universal Garage Lathe

This lathe has been designed especially for use in garages and similar shops where a large variety of machine operations are to be performed, such as turning, cylinder boring, drilling, milling and slotting. The carriage is of special design, the top forming a turntable turret, which carries the cross-slide, a milling vise and other attachments. One end of the table is round and the other square, the latter carrying the cross-slide, as



COMBINED ENGINE AND TURRET LATHE FOR GARAGE AND GENERAL WORK

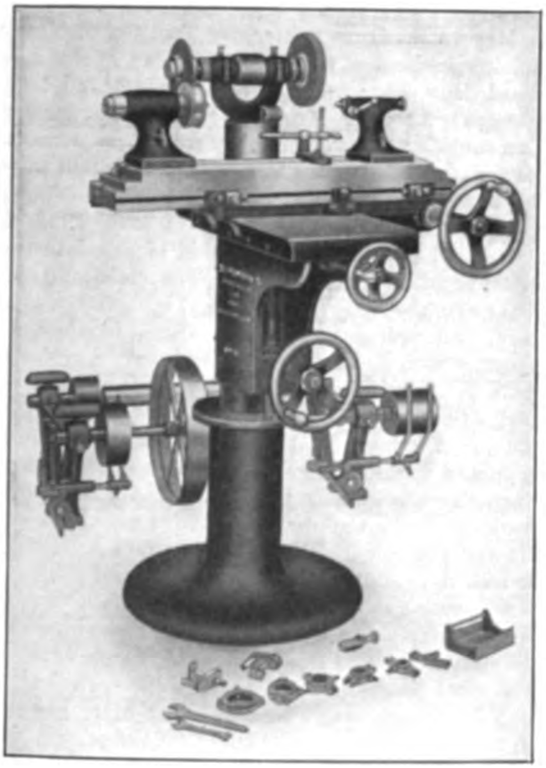
Swings 17 in. over ways, 10 in. over carriage; length of bed, 7 ft.; distance between centers, 52 in.; front bearings, 3½x2⅛ in.; hole through spindle, 1$\frac{3}{16}$ in.; back gearing, 3½ to 1; cuts threads, 8 to 30 per in.; weight, 1,400 lb.

shown. The carriage is worm driven, and there is a power feed on the cross-slide. A 3-step cone is provided; and as there is a reverse in the head, in addition to internal back gears, only a single-belt countershaft is required. The two levers shown operate the back gears

and the reverse. Both belt and gear feed can be used and threads cut in the usual manner. This lathe is built by Samuel K. Landis, Lancaster, Penn.

Universal Grinder

In the design of the universal tool and cutter grinder illustrated the primary considerations were to provide a tool capable of accommodating an exceptionally wide range of work and so to proportion the parts as to insure rigidity of both the table and the head.



UNIVERSAL TOOL AND CUTTER GRINDER
Spindle bearings, 1 in. in diameter, 2[illegible] in. long.

Micrometer adjustment is supplied. The headstock is fitted with bronze bearings, and the spindle is tapped and bored to take the wheel arbors. The countershaft of special design is of the pull-shaft type, easily operated.

It will be observed that in general the machine is developed along standard lines, the table and work controls being conveniently located.

It is a late product of the Simmons Machine Co., Albany, N. Y.

Shell Boring and Turning Lathe

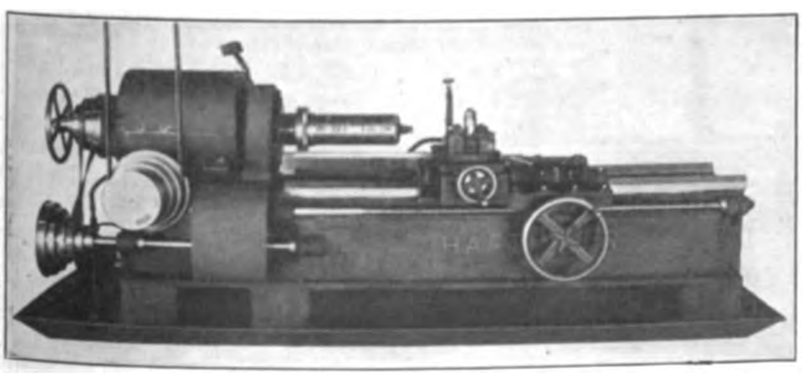
While essentially of the single-purpose type, the lathe shown has been made sufficiently universal to accommodate the various kinds and sizes of shells, ranging from 6 to 12 in. in diameter, and capable, with some elaboration, for some other more or less limited uses.

The headstock and bed are cast integral. The spindle is of forged high-carbon steel, 6⅝ in. in diameter at the front bearing. For shell work it extends out over the ways and carriage to form a boring bar for internal work or an expanding arbor for external work. The spindle is mounted in ball bearings of the radio-thrust type of a size designed to give durability and accuracy. Mounted with the ball bearings is a floating sleeve or collar, which with the oil film acts as a cushion against shocks and chatter.

Upon the spindle is a wormwheel having a phosphor-bronze rim into which engages a quadruple-thread worm. The worm is mounted on the coneshaft and is driven either clutched directly to the coneshaft or through back gears. With the four-step cone this supplies eight speed changes. An oil pocket, which spreads out over the entire head, is designed to give ample lubrication for the worm.

With the reduction obtained in this way the belt cone can be run at high speed, thus enabling a 3-in. belt to apply ample power. It is calculated to belt from the cones directly on a lineshaft, passing over the lathe at a right-angle and thus providing a convenient shop arrangement for handling work to and from the machine. The upper driving cone on the lineshaft is connected by means of a friction clutch which possesses a brake for quick stopping.

The feed mechanism is operated through cone pulleys, providing six changes. Suitable gears reduce the speed to that necessary for the feed screw. This screw operates through a nut under the apron, which moves the carriage forward and back. On the outside of the nut is milled a spiral gear that meshes into a spiral on the handwheel shaft. When the nut is held stationary by means of a friction, power traverse is obtained; when the friction is released, hand traverse is the result. Power quick-return for the carriage is furnished.



SHELL BORING AND TURNING LATHE
Swing over V's, 24 in., over bed 26 in., over carriage [illegible] in.; depth of bed, 20¾ in.; diameter of front spindle bearing, [illegible] in., rear bearing, [illegible], tool slide, 12 in. wide, length of carriage on ways, 12 in., lead screw, 2 in. in diameter; floor space, 5x12 ft., weight, 10,000 lb.

For turning, a four-tool turret post is usually supplied. A special form, in which the tool post is also the tool holder, may also be secured. This form is designed to avoid the overhang of the tool post and tool holder. If desired, the usual form of carriage, embodying the regular cross-slide, may be supplied. The regular form of tailstock may also be applied, as well as other regular attachments.

The lathe shown is a recent development of the Hart-Parr Co., Charles City, Iowa.

Adjustable Drawing Table

The board of the drawing table shown can be adjusted at any angle, thus making it comfortable in operation for both short and tall draftsmen.

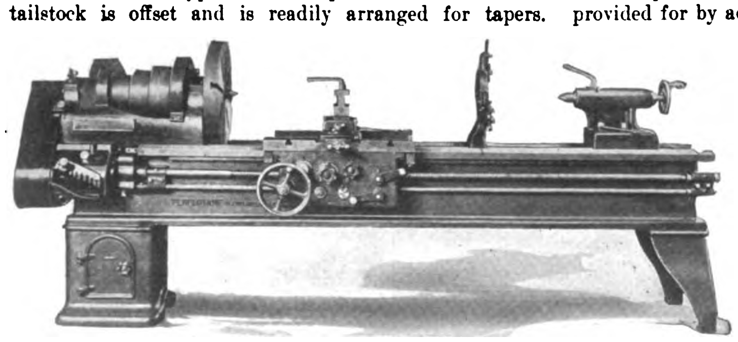
One nut locks both of the board supports located in the rear. The frame is made of cast iron, the lower cross-rod providing a foot rest. The cabinet, made of white pine, has three drawers and a special bottle holder.

ADJUSTABLE DRAWING TABLE
Size of board, 33x55x1¼ in.

The table is a recent product of G. A. Almorth, 966 Grand Ave., New Haven, Conn.

Quick-Change Engine Lathe

The general design and construction of the lathe illustrated follow standard lines. The headstock is of the solid full-webbed type, and the apron is inclosed. The tailstock is offset and is readily arranged for tapers.



DOUBLE BACK-GEARED QUICK-CHANGE ENGINE LATHE
Swing over shears, 20⅝ in.; swing over carriage, 14½ in.; hole through spindle, 2⅛ in.; diameters of cone pulleys, 7.9 and 11 in.; width of driving belt, 3½ in.; width of carriage bridge, 7¼ in.; length of carriage bearing on bed, 27⅜ in.; weight, 3,215 lb.

The machine is equipped with double back gears, which in connection with the three-step cone pulley provide a wide range of spindle speeds. The quick-change feed box provides a range of feeds of 4 to 28 threads per inch.

In addition to the size illustrated the machine is made in two smaller sizes. It is a recent product of the Rockefeller Motor Co., Cleveland, Ohio.

Bullard "Maxi-Pay" Wage Plan

On May 13 the Bullard Machine Tool Co., Bridgeport, Conn., inaugurated a wage-payment plan known as the "Bullard Maxi-Pay Wage Plan." It is founded on a recognition of three great principles in wage payment and cost accounting: First, that production, not wage rate, is the foundation of low cost; second, that skill in producing a specialized product can only be attained through long association with that product; and, third, that skill acquired through a long period of association produces work of superior quality. The statement of the company says:

"Skill and proficiency are the actual foundations of low cost of production—not a low hourly wage rate.

"Skill at the machinist trade may be acquired by years of application in any of a thousand shops, but proficiency in the construction of a highly specialized product, like ours, can be attained only by long association with that product, through which may be developed a knowledge of its workings and an appreciation of the exacting requirements and the construction of the various details which enter into it.

"The longer a man is with us the better is his work, because of his development in skill and his greater knowledge of the special needs in the building of our machines, and, in the final analysis, that man's work costs less even though his hourly wage be considered high, because of its superior quality and the great efficiency with which it has been produced."

The striking features of the plan are the division of all employees into six classes, fixing a minimum wage rate for each class, advancing wage rates in recognition of ability, with the maximum rate dependent upon that ability, and keeping the "continued-service bonus" of 10 per cent. now in force. Thus the plan provides a wage rate that is limited only by the ability of the workman and his particular occupation. Change of occupation is provided for by advancement along definite lines to those who show ability. The provisions in each classification are as follows:

Class AA. Subforemen and leaders in charge of working gangs of mechanics. Maximum rate per hour, dependent on ability. Minimum rate per hour, 55c. Continued-service bonus of 10 per cent. as now in force. Foremen and shop executives will, as far as possible, be selected from Class AA.

Class A. Skilled mechanics of demonstrated first-class ability. Maximum rate per hour, dependent on ability. Minimum rate per hour, 50c. Continued-service bonus of 10 per cent. as now in force. Vacancies in Class AA will be filled from Class A.

Class B. Mechanics of good average ability. Rate per hour, 45c. Continued-service bonus of 10 per cent. as now in force. Class B men will be advanced to Class A when qualified, as shown by efficient and intelligent service.

Class C. Mechanics of limited experience, who by efficiency, interest and service may merit advancement. Rate per hour, 40c. Continued-service bonus of 10 per cent. as now in force. Class C men will be advanced to Class B when qualified, as shown by efficient intelligent service.

Class D. Apprentices, both special and regular. Apprentice wage schedules will be advanced approximately 10 per cent. Continued-service bonus of 10 per cent. as now in force. Class D men, upon completion of apprenticeship, will be advanced to the class for which they qualify.

Class E. Unskilled labor from all classes. Minimum rate per hour, 25c. Maximum rate per hour, dependent upon ability and occupation. Continued-service bonus of 10 per cent. as now in force. In the employment of unskilled labor, preference will be shown to those who can speak and write English and who show qualities which will later warrant advancement. Class E men showing adaptability will be given first opportunity to become skilled by advancement to Class D.

Making British 8-In. Shells in 4½ Hr.—Erratum

The drilling machine shown in Fig. 4 on page 751 was erroneously credited to W. F. & John Barnes Co. instead of to the Barnes Drill Co., as it should have been.

PERSONALS

H. M. Cleaver, for a long period manager of publicity of the Niles-Bement-Pond Co., has been transferred to the Pond works, Plainfield, N. J., to assume new duties.

John G. H. Marvin, for many years president, treasurer and general manager of the L. & I. J. White Co., Buffalo, N. Y., has resigned, and expects to take a well-earned rest before becoming associated with new interests.

H. C. Urbauer has become superintendent of Defiance Screw Machine Products Co., Defiance, Ohio, succeeding S. Thompson, who has relinquished the superintendency to devote his entire time to his office of president and general manager.

W. M. Nones, for some time past secretary and general manager of the Norma Company of America, has been elected president and treasurer and at the same time will continue to be actively in charge of the general management.

Joseph E. Vincent, Jr., for a number of years connected with Wheelock, Lovejoy & Co. and the Swedish Iron and Steel Corporation, has organized the Iron, Steel, Metal and Alloy Co., New York City, of which he is general manager.

OBITUARY

George Reeves, president of the Reeves Brothers Company, Alliance, Ohio, died in Miami, Florida, on April 10.

William J. Fitzsimons, general manager of the Fitzsimons Co., Youngstown, Ohio, died suddenly in that city on May 4, aged 44 years.

Dr. Elmer L. Corthell, president of the American Society of Electrical Engineers and a prominent electrical and consulting engineer for many years, died in Albany, N. Y., May 16, following an operation. He began his engineering work in Providence, R. I., in 1867. He was 76 years of age.

William Stanley, founder of the Stanley Electric Co., acquired some years ago by the General Electric Co., and one of America's pioneer electrical engineers, died in Great Barrington, Mass., May 14, aged 58 years. Mr. Stanley founded his business in Pittsfield, Mass., in 1890, and since that time had been conspicuous in the development of electrical apparatus.

BUSINESS ITEMS

Sherritt & Stoer Co., Inc., 603 Finance Building, Philadelphia, have been appointed the exclusive sales agents of the Gardner Machine Co. for the Philadelphia district.

The Keystone Equipment Co., with offices at Philadelphia and New York City, has just taken title to the patents, good-will and business rights of the Colton Combination Lathe Tool.

In the form of a celebration upon the completion of its new factory addition in New Britain, Conn., the Fafnir Bearing Co. held an entertainment and dance for the employees and friends on May 13. One floor of the new building provided ample room for the purpose, over 800 people attending.

On May 1, the Cleveland offices of the Niles Tool Works Co. were removed from the Rockefeller Building to the Perry Payne Building, at 730 Superior St. The new quarters provide a showroom and store which is stocked with Pratt & Whitney machinery, small tools and gages. This company also represents the Niles-Bement-Pond Co. for its entire line.

In connection with the exportation of shipments to Scandinavian countries, to arrange for which it is necessary to secure letters of assurance in Washington, D. C., it will no doubt be of interest to manufacturers to know that Richard D. Micou, Mills Building, Washington, D. C., who acts as Washington correspondent of the "American Machinist," is in a position to look after the issuance of these letters and the attending details.

Buffalo Engineering Society

The final meeting of the season of the Engineering Society of Buffalo brought together, in the Hotel Statler on the evening of May 3, more than 200 of the members.

At the present time, by a sturdy growth, the membership numbers 450. This membership comprises the various branches of professional engineering—mechanical, electrical, chemical and civic engineering being splendidly represented.

All the present officers were re-elected. They are John Younger, president; W. A. James and Jesse G. Melendy, vice-presidents; Wm. Dollar, treasurer; and W. J. Gamble, secretary.

FORTHCOMING MEETINGS

Master Car Builders' Association. Annual meeting, June 14-17, Atlantic City, N. J. Joseph W. Taylor, secretary, Karpen Building, Chicago, Ill.

American Railway Master Mechanics' Association. Annual meeting, June 17-21, Atlantic City, N. J. Joseph W. Taylor, secretary, Karpen Building, Chicago, Ill.

American Society for Testing Materials. Annual meeting June 27 to July 1, 1916, Hotel Traymore, Atlantic City, N. J. Edgar Warburg, secretary, University of Pennsylvania, Philadelphia, Penn.

American Society of Mechanical Engineers. Monthly meeting first Tuesday. Calvin W. Rice, secretary, 29 West Thirty-ninth St., New York City.

Boston Branch National Metal Trades Association. Monthly meeting on first Wednesday of each month, Young's Hotel. W. W. Poole, secretary, 40 Central St., Boston, Mass.

Providence Association of Mechanical Engineers. Monthly meeting fourth Wednesday each month. J. A. Brooks, secretary, Brown University, Providence, R. I.

New England Foundrymen's Association. Regular meeting second Wednesday of each month. Exchange Club, Boston, Mass. Fred F. Stockwell, 205 Broadway, Cambridgeport, Mass.

Engineers' Society of Western Pennsylvania. Monthly meeting third Tuesday; section meeting, first Tuesday. Elmer K. Hiles, secretary, Oliver Building, Pittsburgh, Penn.

Rochester Society of Technical Draftsmen. Monthly meeting, last Thursday. O. L. Angevine, Jr., secretary, 857 Genesee St., Rochester, N. Y.

Superintendents' and Foremen's Club of Cleveland. Monthly meeting third Saturday. Philip Frankel, secretary, 310 New England Building, Cleveland, Ohio.

Western Society of Engineers, Chicago, Ill. Regular meeting first Wednesday evening of each month, excepting July and August. J. H. Warder, secretary, 1735 Monadnock Block, Chicago, Ill.

Philadelphia Foundrymen's Association. Meetings first Wednesday of each month. Manufacturers' Club, Philadelphia, Penn. Howard Evans, secretary, Pier 45 North, Philadelphia, Penn.

Technical League of America. Regular meeting second Friday of each month. Oscar S. Teale, secretary, 35 Broadway, New York, N. Y.

Prices--Materials and Supplies

IRON AND STEEL

Pig Iron—Quotations were current as follows at the points and dates indicated:

	May 19, 1916	One Month Ago	One Year Ago
No. 2 Southern Foundry, Birmingham	$15.00	$15.00	$9.50
No. 2 X Northern Foundry, New York	20.75	20.75	14.25

New and Enlarged Shops

If you are in need of machinery or supplies, the first thing to do is to consult the Buying Section. If you cannot find just what you want, send us particulars, and we will be glad to publish it free of cost, thus putting you in touch with reliable manufacturers.

METAL WORKING

NEW ENGLAND STATES

Bids will be received by Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., until June 6, for furnishing and delivering at Portsmouth, N. H., 18-in. turret lathe, 1½x 18-in. turret lathes, milling machine and 2-spindle drill presses.

We have been advised that D. J. Sullivan, 660 Cottage St., New Bedford, Mass., will construct a garage at New Bedford. Estimated cost, $10,000.

We have been advised that the Winter Bros. Co., manufacturer of taps and dies, plans to construct a 1-story, 40x 125-ft. addition to its plant at Wrentham, Mass.

Bids will be received until June 6 by Navy Department, Washington, D. C., for 2 drilling machines and 1 chucking outfit under Schedule 9633 for Newport, R. I.

Fire, May 9, damaged the foundry of the New London Marine Iron Works at New London, Conn. Loss, $5,000.

MIDDLE ATLANTIC STATES

The Lehigh Valley R.R. contemplates shops on the flats west of the Chemung River, Athens, N. Y. E. B. Ashby, New York, N. Y., Ch. Engr.

The Simplex Seamless Tube Corporation, Buffalo, N. Y., recently incorporated by A. W. Sawyer, Charles A. Hamlin, and others, will construct a factory at Buffalo for the manufacture of seamless tubes.

A 2-story factory will be constructed at 102 Broadway, Buffalo, N. Y., by the Star Plating Works, manufacturer of copper plating.

The Engle Aëroplane and Motor Co., D. S. Morgan Bldg., Buffalo, N. Y., recently incorporated with $750,000 capital stock, by Albert J. Engel and O. J. Weimert, Buffalo, and M. Mauran, Niagara Falls, has absorbed the Coombs Aëroplane Co., Inc., and taken over that company's plant at Dewpew, N. Y., a suburb of Buffalo. The new company will equip the plant for the manufacture of powerful and speedy flying boats of the latest design and aëroplanes for sport, pleasure and business purposes.

The Crescent Tool Co., Foote Ave. and Harrison St., Jamestown, N. Y., is enlarging its plant.

The Nathan Manufacturing Co., 101 Park Ave., New York, N. Y., manufacturer of patented injectors, has awarded the contract for the construction of a new plant at Flushing, N. Y. (Borough of Queens). Estimated cost, $500,000.

Plans have been prepared by F. Grad, American National Bank Bldg., Newark, N. J., for a 3-story addition to the jewelry factory of John F. Schrink & Son, Emmet St., Newark. Estimated cost, $25,000. Noted May 4.

Henry Gobert, Newark, N. J., plans to construct a 1-story brick garage at 239-41 Central Ave., Newark, N. J. Estimated cost, $11,000.

The Hyatt Roller Bearing Co. has awarded the contract for the construction of a 9-story reinforced-concrete factory at 5th and Middlesex St., Newark, N. J. Estimated cost, $235,000.

The Niles-Bement-Pond Co., Plainfield, N. J., manufacturer of machinery, is having plans prepared by Harris & Richard, Arch., Drexel Bldg., Philadelphia, Penn., for an addition to its plant.

The Steel Car Forge Co., Ellwood City, Penn., a subsidiary of the Standard Steel Car Co., is building a new machine shop.

The Kutztown Foundry and Machine Works, 1421 Chestnut St., Philadelphia, Penn., will build an addition to its plant at Kutztown, Penn.

The Evans Mould and Machine Co., Uniontown, Penn., has awarded the contract for the construction of a new foundry.

The Myerberg Lighting Co., 418 North Calvert St., Baltimore, Md., will establish a factory for the manufacture of lighting fixtures.

The contract has been awarded for the construction of a garage and repair shop at Brooklyn, Md., for William Smith.

Bids will be received by Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., until June 6, for furnishing and delivering 36-in. triple geared lathe at Washington.

Isaac T. Mann, Washington, D. C., plans to construct a 3-story service plant.

SOUTHERN STATES

According to press reports a brick garage and machine shop will be constructed at Danville, Va., by J. C. Holmbe.

The Carter Iron Manufacturing Co., Charleston, W. Va., plans to construct a factory at Paden City, W. Va.

The Universal Plow Co., Florence, Ala., plans to construct a foundry for the manufacture of malleable iron.

Robert Burrows, Jr., Johnson City, Tenn., is in the market for garage equipment, including air compressors, tanks, etc.

The Nicholson Furnace Co. plans to construct a factory at Louisville, Ky., for the manufacture of furnaces.

MIDDLE WEST

Plans have been prepared for the construction of a 2-story, 76x250-ft. garage for the Summit Auto Garage Co. at Akron, Ohio. Estimated cost, $30,000.

Bids are being received by McLaughlin & Hulsken, Arch., 610 Savings Bank Bldg., Lima, Ohio, for the construction of a pattern shop at Bucyrus, Ohio, for the Carroll Foundry Co. Estimated cost, $25,000.

The United Steel Co. is constructing additions to its plant at Canton, Ohio. Estimated cost, $1,500,000.

We have been advised that the contract has been awarded for the construction of a factory for the American Tool Works at Cincinnati, Ohio.

The W. S. Bidle Co., 1411 East 45th St., Cleveland, Ohio, has been granted a permit for the construction of an addition to its plant at Cleveland for the heat treating of steel.

The Crucible Steel Forge Co. will build an addition to its plant on Carnegie Ave., Cleveland, Ohio.

The contract has been awarded for the construction of an addition to the factory of the Cuyahoga Stamping Machine Co., East 152nd St., Cleveland, Ohio. Estimated cost, $5,000.

Plans have been prepared for the construction of a 3-story addition to the garage of A. R. Davis Motor Co., at 2020 Euclid Ave., Cleveland, Ohio. Estimated cost, $20,000.

Plans are being prepared for the construction of a 1-story garage at Cleveland, Ohio, for the Balle Bros. Co. Estimated cost, $20,000.

The National Lamp Works is constructing an addition to its plant at 1764 East 45th St., Cleveland, Ohio. Estimated cost, $7,000. Noted May 11.

The National Screw and Tack Co. will construct an addition to its factory at 7300 Stanton Ave., Cleveland, Ohio. Estimated cost, $16,000.

Bids will be received until June 1 for the construction of a plant at the foot of West 65th St., Cleveland, Ohio, for the Northern Blower Co., 4515 Storer Ave., Cleveland. Estimated cost, $20,000. Noted May 11.

The Park Drop and Forge Co., 730 East 79th St., Cleveland, Ohio, has awarded the contract for the construction of an addition to its factory at Cleveland.

The contract has been awarded for the construction of a 2-story, 60x10-ft. factory at Cleveland, Ohio, for the West Steel Castings Co., 805 East 70th St., Cleveland. Noted May 18.

The contract has been awarded for the construction of a 2-story factory on East 40th St., Cleveland, Ohio, for Warwick Bros., manufacturer of japanning and enameling.

The H. J. Harrold Tool Co. is constructing a 40-126-ft. addition to its plant at Columbiana, Ohio. Noted Jan. 27.

The contract has been awarded for the construction of shops at Columbus, Ohio, for the Hocking Valley Railway Co.

The Moore-Eastwood Manufacturing Co., Dayton, Ohio, is equipping a plant at Dayton for the manufacture of gages, dies, tools, fixtures, etc.

The Kressler Auto Co. plans to construct a 2-story, 100x 200-ft. addition to its plant at Fostoria, Ohio.

The Crown Pipe and Foundry Co. its constructing an addition to its foundry and machine shop at Jackson, Ohio.

The contract has been awarded for the construction of a 3-story, 50x200-ft. garage for J. H. Blattenberg, M. D., 128 South Union St., Lima, Ohio. Estimated cost, $25,000. Noted May 4.

The Lima-Overland Co. is constructing a factory at Lima, Ohio.

Steiner Bros., manufacturer of tools, jigs, fixtures, special machinery, etc., is enlarging its plant at Lima, Ohio. Noted Nov. 25.

The Humphreys Manufacturing Co., manufacturer of pumps and plumbers' supplies, plans to construct an addition to its plant at Mansfield, Ohio. Estimated cost, $5,000.

The Idea Wheel Co., manufacturer of a patent spring auto wheel, has increased its capital from $50,000 to $150,000, and plans to construct a plant at Massillon, Ohio.

Fire, May 10, destroyed the plant of the Spicer Manufacturing Co., foundry and machine works, at New Philadelphia, Ohio. Loss, $30,000.

The Buckeye Incubator Co. will construct an addition to its plant at Springfield, Ohio.

The Robbins & Myers Co., manufacturer of electric motors, generators and fans, has awarded the contract for the construction of the second unit to its plant at Springfield, Ohio.

The contract has been awarded for the construction of a 1-story, 50x140-ft. garage at Toledo, Ohio, for Harry G. Hammond, 422 West Bancroft St., Toledo. Estimated cost, $10,000.

The Hobart Manufacturing Co., manufacturer of electric coffee mills and meat choppers, is constructing a 3-story, 50x115-ft. addition to its plant at Troy, Ohio.

The Standard Car Construction Co plans to construct a plant at Warren, Ohio. Estimated cost, $1,000,000.

The National Car Coupler Co is constructing an addition to its plant at Attica, Ind. Estimated cost, $100,000. Noted Mar 23 and Apr. 27.

The A-B Stove Co. is constructing an addition to its foundry at Battle Creek, Mich

We have been advised that the contract has been awarded for the construction of a factory at Battle Creek, Mich, for the Rich Twist Drill Co, Chicago Ill. Estimated cost, $45,000. Noted May 4 and 11.

The United Steel and Wire Co is constructing an addition to its plant on Burchard St., Battle Creek, Mich.

Bids are being received by Smith, Hinchman & Grylls, Arch., 710 Washington Arcade, Detroit, Mich., for the construction of a factory for the Hygeia Filter Co. at Hamtramck, Mich.

Work will soon be started on the construction of a factory at Beard and Green Ave., Detroit, Mich., for the Ireland & Matthews Manufacturing Co., manufacturer of sheet-metal goods, 61-79 Iron St., Detroit.

The Michigan Steel Boat Co. is constructing a 4-story factory at Detroit, Mich.

Plans have been prepared for the construction of a factory at Detroit, Mich., for the Saxon Motor Co.

The Trippensee Manufacturing Co., 2679 East Grand Blvd., Detroit, Mich., manufacturer of automobile bodies, plans to construct an addition to its plant at Detroit.

The contract has been awarded for the construction of a 2-story, 100x158-ft. garage and factory at Detroit, Mich., for A. Wegner & Son Co. Estimated cost, $50,000. Noted Feb. 17.

The Superior Veneer and Cooperage Co will rebuild its mill at Escanaba, Mich., which was destroyed by fire

The Argo Motor Co contemplates purchasing a site on Wildwood Ave., Jackson, Mich., and plans to construct a plant

The Reo Motor Car Co is constructing a 1-story, 95x128-ft. addition to its heat treating factory at Lansing, Mich.

The L. O. Gordon Manufacturing Co., manufacturer of cam shafts and other motor specialties, will establish a factory at Muskegon, Mich

The Kawneer Manufacturing Co., manufacturer of metal architectural specialties, plans to construct an addition to its plant at Niles, Mich

The Anti-Friction Lubricant Co. recently organized, will construct a factory at St Joseph, Mich

The Peters Bros Manufacturing Co., manufacturer of ironing machines and tapping chucks, will build an addition to its factory at Algonquin, Ill Estimated cost, $15,000.

Plans have been prepared for the construction of a factory at Aurora, Ill., for the Aurora Metal Cabinet Works.

The contract has been awarded for the construction of a 50x150-ft. addition to the plant of the Chicago Bearing Metal Co., 43rd and Western Ave., Chicago, Ill Noted May 18.

The Cole Manufacturing Co., manufacturer of stoves, 3218 South Western Ave., Chicago, Ill has awarded the contract for the construction of a 3-story factory at 2436 Bross Ave., Chicago. Estimated cost, $75,000 Noted May 18

The Findeisen & Kropf Manufacturing Co., manufacturer of carburetors, will build a 25x110-ft. foundry at 2519 West 21st St., Chicago, Ill.

The contract has been awarded for the construction of an addition to the assembling plant on Michigan St Chicago, Ill., for the Ford Motor Co Estimated cost, $100,000 Noted May 11

The Independent Can Co., Kinzie and Wood St., Chicago, Ill., will construct a 2-story, 25x135 ft factory at 403 North Wood St., Chicago, Ill. Estimated cost, $20,000

Bids are being received by John Ahlschlager & Son, Arch., 111 West Washington Ct Chicago, Ill for the construction of a 1-story garage at 2641 North California Ave Chicago, for H. P Koechneke, 2710 Iowa St. Estimated cost, $10,000. Noted May 18

The American Wire Fence Co is remodeling its factory at Libertyville, Ill., and will install new equipment

The J. I. Case Threshing Machine Co will construct an addition to its plant at Peoria, Ill

Plans have been prepared for the construction of a plant at Peoria, Ill., for the Keystone Steel and Wire Co Estimated cost, $1,750,000 Noted May 4

The contract has been awarded for the construction of a plant at North Cairo, Ill (Cairo post office), for the Pioneer Pole and Shaft Co

The Kankakee Universal Welding Co., manufacturer of wire wheels for automobiles will reconstruct its factory at St Anne, Ill., which was recently destroyed by fire with a loss of $100,000.

The Appleton Wire Works is constructing a factory at Appleton, Wis

Plans are being prepared for the construction of additions to the plant of the Fairbanks Morse Manufacturing Co., manufacturer of windmills and engines, at Beloit, Wis Estimated cost, $400,000. C H Morse, Jr., is Pres Noted May 11.

The Four Wheel Drive Automobile Co plans to construct a 100x175-ft. addition to its factory at Clintonville, Wis

The Nelson Manufacturing Co., manufacturer of tank heaters, plans to construct an addition to its factory at Deerfield, Wis.

The Davidson Manufacturing Co manufacturer of automatic devices and attachments for typewriters will equip a plant at 613 Williamson St., Madison Wis.

The Allis-Chalmers Manufacturing Co., manufacturer of engines and heavy machinery, plans to construct an addition to its plant at Milwaukee, Wis.

Hugo Deuster will contract a garage at 5th and Prairie St., Milwaukee, Wis. Estimated cost, $36,000.

The Universal Foundry Co. is constructing a foundry at Oshkosh, Wis. Robert Ziebell is Pres.

The Warning Sheet Metal Co. has awarded the contract for the construction of a 2-story addition to its plant at Ceape and State St., Oshkosh, Wis. Noted Dec. 23.

The Gorton Fence Co., manufacturer of wire fence, contemplates constructing a factory at Racine, Wis., George Gorton, 1165 13th St., Racine, interested.

Bids are being received by Chandler & Park, Arch., 400 Main St., Racine, Wis., for the construction of a 1-story, 65x250-ft factory at Racine for Perfex Radiator Co., 15th St. Estimated cost, $12,000.

Preliminary plans have been prepared for the construction of a plant at Superior, Wis., for John G. Barsdale, 618 Tower Ave., Superior, manufacturer of motor trucks. Estimated cost, $50,000.

WEST OF THE MISSISSIPPI

The contract has been awarded for the construction of a 300x900-ft. locomotive shop at Burlington, Iowa, for the Chicago, Burlington & Quincy R.R. Estimated cost, $750,000. T. E. Calvert, 547 West Jackson Blvd., Chicago, Ill., is Ch. Engr. Noted May 11.

Ford Motor Co., Detroit, Mich., plans to construct a plant at Duluth, Minn. Estimated cost between $500,000 and $1,000,000.

The Berg Bros. Manufacturing Co., manufacturer of sheet iron specialties, plans to construct an addition to its factory at 2924-27 27th St., Minneapolis, Minn.

The Redell Motor Car Co., Joplin, Mo., recently incorporated with $12,000 capital stock, plans to equip a repair and machine shop in connection with a garage. A. T. Blackwell, Joplin, interested.

The Ford Motor Co. plans to construct a factory at Oak and McGee St., Kansas City Mo.

J. Goldberg & Son plans to construct a 115x150-ft. addition to its steel plant at Independence and Winchester Ave., Kansas City, Mo.

A plant for the manufacture of lawn mowers will be equipped by the Leidecker Lawn Mower Co., Muskogee, Okla. About $14,000 worth of machinery will be required.

WESTERN STATES

Bids will be received by Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., until June 20, for furnishing and delivering one 40 ton traveling crane at Puget Sound Navy Yard, Bremerton, Wash.

Bids will be received until June 13 by Navy Department, Washington, D. C., for 3 precision lathes, and 1 bolt threading machine under Schedule 9625, and 1 planer and matcher under Schedule 9624 for Puget Sound Navy Yard, Bremerton, Wash.

Leach Bros will build a 1-story foundry at 2926 1st Ave., Seattle, Wash., and will install new equipment.

B. Lewis, State Engr., Salem, Ore., is advocating the construction of a nitrate plant at Bonneville, Ore., on the Columbus River, for the manufacture of explosives in time of war and fertilizers in times of peace. L. F. Harza, Engr., Portland, Ore., is interested.

The Motor Ship Construction Co. will construct a shipbuilding plant at Portland, Ore. M. A. Reed, Portland, Ore., is interested.

The contract has been awarded for the construction of a garage at Union Ave. and Weidler St., Portland, Ore., for C. N Nelson.

The Northwest Steel Co. plans to construct a 1-story addition to its plant on Sheridan St., Portland, Ore. Estimated cost, $7,500

Plans are being prepared by R. F. Felchin, Arch., for the construction of a garage and machine shop on J St., Fresno, Calif., for C B Shaver. Estimated cost, $10,000.

The Aluminum Products Co., La Grande, Ill., has purchased a site at 12th St and 1st Ave., Oakland, Calif., and will construct a branch plant.

J Carson plans to construct a reinforced-concrete garage at Quincy, Calif.

The Pinal Dome Oil and Refining Co. has purchased a site on East 1st St., Santa Ana, Calif., and plans to construct a garage and machine shop.

Eliot E Bradley, Fresno, Calif., representing the Studebaker Motor Car Co., plans to establish a garage and machine shop at Visalia, Calif.

CANADA

The General Car and Machinery Co will rebuild its plant at Montmagny, Que., which was recently destroyed by fire with a loss of $300,000

H Morgan & Co., 16 Beaver Hall Hill, Montreal, Que., will construct a garage at Montreal. Estimated cost, $10,000.

The American Radiator Co., Ltd., has been granted a permit for the construction of an addition to its plant at Brantford, Ont Estimated cost, $8,000.

The White Sewing Machine Co., Cleveland, Ohio, has purchased the plant of the Raymond Sewing Machine Co. at Guelph, Ont., and plans to enlarge and equip plant. Estimated cost, $200,000.

E Leonard & Sons, manufacturer of engines and boilers, plans to construct a 70x70-ft. addition to its factory at London, Ont

The Burrows Refining Co., 629 Wellington St., Ottawa, Ont., is having plans prepared for the construction of a nickel refining plant at Ottawa. Estimated cost, $30,000.

The Dominion Stove and Foundry Co. plans to construct an addition to its plant at Penetanguishene, Ont., and is in the market for equipment.

The Electrical Fttings and Foundry Co., Ltd., Preston, Ont., will install new equipment at plant at Preston.

The Metal Shingle and Siding Co., Preston, Ont., is in the market for equipment for plant at Preston.

Fire, May 11 destroyed the plant of the Lampman Pump Works, Peel St., Simcoe, Ont.

The McClary Manufacturing Co., manufacturer of stoves, plans to construct an addition to its plant at 177 King St., W., Toronto, Ont.

Work will soon be started on the construction of a factory at Toronto, Ont., for the Martin Pump and Machine Co., 43 Davies Ave., Toronto. Estimated cost, $15,000.

The Breen Motor Co. will construct a 50x116-ft. garage on Broadway, Winnipeg, Man. Estimated cost, $15,000.

The Canadian Western Steel Co. has taken over the plant of the Redcliffe Rolling Mills at Redcliffe, Alta, and will construct and addition to same. Estimated cost, $15,000. The company is in the market for machinery estimated to cost, $60,000.

GENERAL MANUFACTURING

NEW ENGLAND STATES

The E. F. Bell Shoe Co. plans to enlarge its plant at Bow and Rantoul St., Beverly, Mass.

Plans are being prepared by Jencks & Ballon, Arch., Providence, R. I., for the construction of a 1-story, 60x100-ft. and two 1-story, 19x95-ft. additions to the plant of the Constock-Cheney & Co., manufacturer of ivory goods, at Ivoryton, Conn.

MIDDLE ATLANTIC STATES

An addition will be built to the plant of the C. M. Bott Furniture Co., 170 Leslie St., Buffalo, N. Y.

The Buffalo Weaving and Belting Co., Chandler St., Buffalo, N. Y., manufacturer of cotton webbing and rubber and cotton belting, will build an addition to its plant.

E. S. Ward & Co., 418 Frelinghuysen Ave., and Hugh Smith Co., 210 Central Ave., Newark, N. J., have been consolidated into the General Leather Co. and will construct a plant on Frelinghuysen Ave. for the manufacture of automobile, carriage and furniture leather.

The contract has been awarded for the construction of an addition to the plant of the Maltbie Chemical Co., High St., Newark, N. J. Estimated cost, $25,000.

The Betany Worsted Mills, Passaic, N. J., plans to construct a plant at Wallington, N. J.

Fire, May 8, destroyed part of the plant of the Barbour Flax Spinning Co., Paterson, N. J., manufacturer of threads, twines, etc. Loss, $50,000.

The Gaede Silk Dyeing Co., Paterson, N. J., plans to enlarge its plant.

The portion of the plant of the Dellon Tire and Rubber Co., Trenton, N. J., recently destroyed by fire with a loss of $20,000, will be rebuilt.

Plans are being prepared for a 2-story addition to the plant of Charles P. Cochrane Co., Philadelphia, Penn., manufacturer of carpets.

The Lee Tire and Rubber Co., Pittsburgh, Penn., plans to construct a new plant.

SOUTHERN STATES

The Libby Owens Co., Charleston, W. Va., has awarded the contract for the construction of a glass plant at Kanawha City, W. Va.

The contract has been awarded for the construction of a factory for the J and D. Tire and Rubber Co., Charlotte, N. C. Estimated cost, $500,000. C. C. Coddington, Charlotte, interested. Noted Apr. 27.

The High Point Hosiery Mills, High Point, N. C., plans to enlarge its plant. Estimated cost, $30,000.

The Kelly Button Mills, Klinton, N. C., plans to construct an addition to its plant for the manufacture of hosiery. Estimated cost, $100,000.

S. B. and K. S. Tanner and associates, Rutherfordton, N. C., plan to construct a spinning mill at Rutherfordton.

The T. A. and A. Manufacturing Co., Fayetteville, Tenn., recently organized, plans to establish a plant for the manufacture of sanitary well buckets. E. H. Taylor, Fayetteville, interested.

The Ohio Falls Dye and Finishing Works, 719 East Madison St., Louisville, Ky., plans to construct an addition to its plant and install new machinery. J. J. Brown, Mgr.

MIDDLE WEST

The Miller Rubber Co. is constructing a factory at Akron, Ohio. Estimated cost, $90,00. Noted Dec. 30 and May 11.

The Buckeye Ribbon and Carbon Co., 311 St. and Clair Ave., Cleveland, Ohio, plans to construct a factory at East 55th and Spencer Ave., Cleveland. Estimated cost, $25,000. James Donovan is Pres.

The contract has been awarded for the construction of a factory on West 116th St., Cleveland, Ohio, for Henry A. Lindsley, manufacturer of paper fiber, 1366 West 70th St., Cleveland. Estimated cost, $9,00. Noted Jan. 20.

Bids are being received by Forest City Engineering Co., Engr., 512 Hippodrome Bldg., Cleveland, Ohio, for the construction of a factory at Cleveland for the National Artificial Silk Co., 735 Central Ave. Estimated cost, $300,000. Noted May 18.

Work will soon be started on the construction of a factory at East Norwood, Ohio (Cincinnati post office), for the North Western Chemical Co.

The Emery Candle Co. plans to construct an addition to its plant at Ivorydale, Ohio (Cincinnati post office).

The Kelly Springfield Tire Co., Akron, Ohio, will construct additions to its plant at Wooster, Ohio.

The Schacht Rubber Co. plans to construct a 2-story addition to its factory at Huntington, Ind.

The American Leather Products Co. has been granted a permit for the construction of a factory at 22nd and Montcalm St., Indianapolis, Ind.

Fire, May 8, damaged the plant of the Cadillac Chemical Co. at Cadillac, Mich. Loss between $50,00 and $100,000.

The contract has been awarded for the construction of a packing plant at Elgin, Ill., for the Kerber Packing Co. Estimated cost, $150,000. Noted Apr. 13.

Preliminary plans are being prepared for the construction of an addition to the plant of the Combined Locks Paper Co., Appleton, Wis.

The Federal Rubber Manufacturing Co. plans to construct 3 factory buildings at Cudahy, Wis.

The John Hoberg Paper Co. will construct a 75x175-ft. addition to its plant at Green Bay, Wis.

Plans have been prepared for the construction of an addition to the plant of the Cudahy Packing Co., at Springfield, Ill. Estimated cost, $13,000.

WEST OF THE MISSISSIPPI

W. F. Schnuckle plans to enlarge his broom factory at Duluth, Minn.

The Hastings Commercial Club is interested in the construction of a canning factory at Hastings, Minn. Estimated cost, $60,000.

Plans are being prepared by J. C. Sunderland, Arch., for the construction of a 9-story factory for the H. D. Lee Mercantile Co. at Kansas City, Mo. Noted Sept. 30.

G. W. and R. P. Hart plan to construct a canning plant and cotton gin at Arkadelphia, Ark.

The Rogers Handle Co., Paragould, Ark., plans to construct a factory at Jonesboro, Ark.

The Creechville Farmers Gin Co. plans to install new machinery at its cotton gin at Creechville, Tex.

The contract has been awarded for the construction of a cotton gin at Ringling, Okla., for J. C. Palmer, Orr, Okla. Estimated cost, $12,000. Noted Apr. 20.

B. L. Fields and associates plan to construct a canning factory at Temple, Tex.

The Tynan Gin Co. plans to construct a cotton gin at Tynan, Tex. Estimated cost, $12,000.

WESTERN STATES

The Pacific Western Chemical Co., San Francisco, Calif., plans to construct a plant at Medford, Ore.

The American Sugar Beet Co. plans to enlarge and improve its plant at Oxnard, Calif. Estimated cost, $100,000.

CANADA

The Columbus Rubber Co., 146 Iberville, St., Maisonneuve, Que., will construct an addition to its plant at Maisonneuve. Estimated cost, $20,000.

The Wayagamack Pulp and Paper Co., Ltd., will construct an addition to its plant at Three Rivers, Que. Estimated cost, $11,000.

Work will soon be started on the construction of a chemical plant at Merritton, Ont., for the Riordan Pulp and Paper Co. Estimated cost, $35,000.

The Solid Leather Co. plans to construct an addition to its plant at Preston, Ont. Estimated cost, $25,000.

Plans have been prepared for the construction of an addition to the plant of the Wayagamack Pulp and Paper Co. at Three Rivers, Ont.

Business and Patriotism

A Non-partisan Appeal to the Nation

THE WHITE HOUSE
Washington

April 21, 1916.

To the Business Men of America:

I bespeak your cordial cooperation in the patriotic service undertaken by the engineers and chemists of this country under the direction of the Industrial Preparedness Committee of the Naval Consulting Board of the United States.

The confidential industrial inventory you are asked to supply is intended for the exclusive benefit of the War and Navy Departments, and will be used in organizing the industrial resources for the public service in national defense.

At my request, the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers and the American Chemical Society are gratuitously assisting the Naval Consulting Board in the work of collecting this data, and I confidently ask your earnest support in the interest of the people and government of the United States.

Faithfully Yours, Woodrow Wilson

Drop Forging the Russian Cruciform Bayonet

By John H. Van Deventer

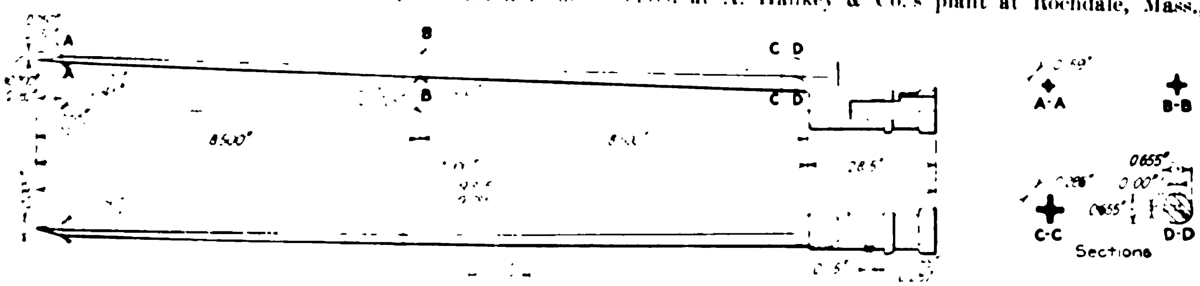
SYNOPSIS—Very little has been published relative to the forging of alloy steels under the drop hammer. This article describes the production of a Russian bayonet forging from a high-carbon chrome-nickel-manganese alloy steel and gives the successive steps in detail, from shearing the rough bars to pickling the finished forging. The machines used, special fixtures and apparatus, drop and trimming dies are shown, and the production time on each operation is also given.

Attempts to produce high-carbon forgings under the drop hammer have been followed by numerous failures, and the adventurous smiths who tried, but did not succeed, went sadly back to slower but surer methods. It is discouraging, for example, to be forced to produce certain edged tools, such as chisels, with the expenditure of many light blows and much labor; but the "cold refining" of the metal which comes under the skillful strokes of the toolsmith just as the work is losing its redness cannot be imitated by the elephantine impact of a ton drop.

Again, as the carbon goes up, the critical temperature comes down, bringing with it the high limit of temperature at which the piece may be worked without decarburizing. Unfortunately, the low limit at which forging is possible does not come down under these conditions, but rather goes up with the higher tensile strength, and thus the working limits of temperature narrow very quickly.

A bayonet forging, due to the exacting requirements that are placed upon the finished article, must retain all the qualities of strength and temper that are associated with high-carbon steel. It must not only possess strength and hardness, but to meet the twisting and bending tests to which it is subjected must have a spring-like temper and flexibility. Thus it will be noticed that the feat of producing a finished forging in two heats is not a mean one.

The process of doing this, as related here, was observed at A. Hankey & Co.'s plant at Rochdale, Mass.,



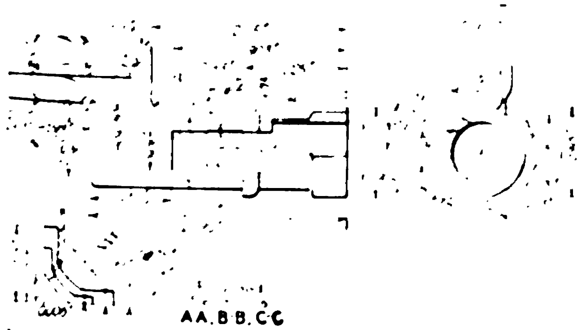


FIG. 1. DETAILS AND LIMITS OF THE RUSSIAN CRUCIFORM BAYONETS

where Russian cruciform bayonets are being manufactured. Not only is the bayonet forged complete in two heats, but the total man-time required for shearing the bars, drawing under the helve hammer, drop forging, trimming, breaking the tong hold, annealing, pickling, washing, neutralizing and baking is but $2\frac{3}{4}$ min. per bayonet—and this includes tending the heating furnaces also!

The composition of the steel used in the Russian bayonet must be such as to give in an annealed test piece the following mechanical test:

Tensile strength	100,000 lb. per sq.in.
Elastic limit	70,000 lb. per sq.in.
Minimum elongation	17 per cent. (in 2 in.)
Minimum reduction of area	30 per cent.

These are fairly stiff requirements in an annealed test piece, and to meet them steel is used having the following composition:

	Per Cent.
Carbon	0.60 to 0.70
Manganese	0.60 to 0.70
Silicon	0.10 to 0.20
Phosphorus not over	0.03
Sulphur not over	0.04
Chromium	0.30 to 0.50
Nickel	0.30 to 0.50

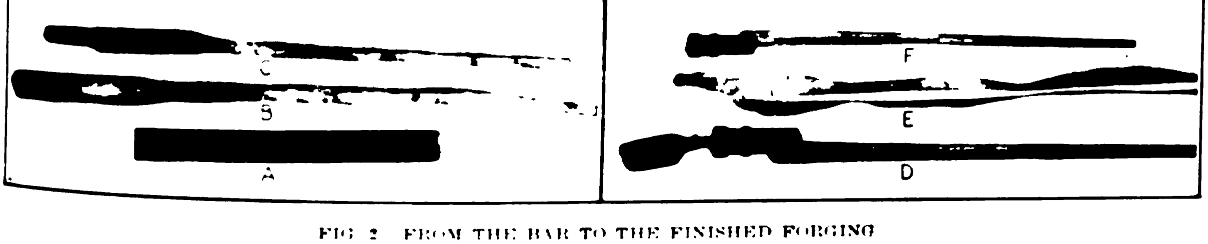

FIG. 2. FROM THE BAR TO THE FINISHED FORGING

The manganese, chromium and nickel make this steel in reality an openhearth spring steel and also have the very desirable effect of increasing the critical temperature that would correspond to the carbon content of a similar steel without them, from 1,800 to 2,000 deg. F., thus giving much wider limits than would otherwise be had.

The operator who takes care of drawing the blade and tong hold also looks after the furnace in which the round blanks are heated to a temperature of 1,700 deg. F. The furnaces for all the forging operations are of the over-fired oil-burning muffle type, the fuel being crude oil vaporized by dry steam at 125 lb. pressure. Less slag-

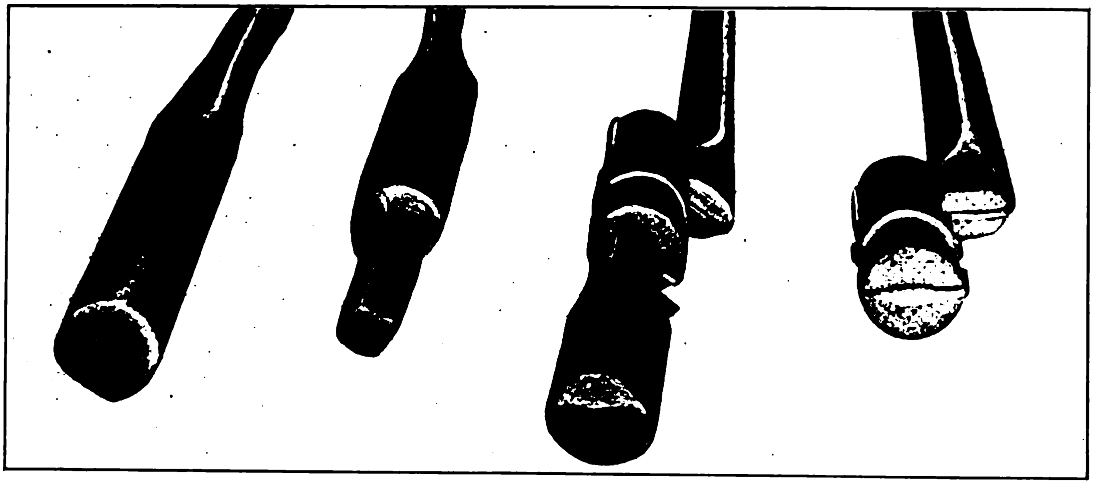

FIG. 3. CHANGES MADE IN THE BAYONET BUTT DURING FORGING

A glance at the limits and details of the Russian bayonet, as set forth in Fig. 1, will show that the forging from which the finished bayonet is made must be held closely to size. A thirty-second of an inch all over is allowed for this finish, and any decarburizing, scaling or etching in the pickle bath must not penetrate beyond this thirty-second-inch skin.

The changes that occur during the process of transforming the $1\frac{1}{16}$-in. round bars into finished forgings are illustrated in Figs. 2 and 3, the latter being an enlarged view of the butt ends showing the tong holds. In Fig. 2, *A* shows an 8-in. length as it is sheared from the bar, this being the correct size of the blank for drawing. At *B* and *C* are seen respectively the blade and the tong hold drawn, both of these draws being made under the helve hammer. At *D* is shown a bayonet that has been dropped and trimmed, but that still retains the tong hold, while the flash, or waste that is forced out between the upper and lower die faces, is shown in its entirety at *E*. The finished forging is depicted at *F*.

An alligator shear chews up the bar into the 8-in. lengths at the rate of 20 bites per minute, the operator merely pushing the stock against a stop each time that the shear blades open.

The metal in a bayonet must be refined, somewhat as is the metal in a chisel blade. As stated previously, the heavy impact of the drop hammer, while it will squeeze the hot material into shape in record time, will not refine it. This is accomplished, however, in the operation that immediately precedes the drop forging—namely, that in which the blade and tong hold are drawn out under the helve hammer. This operation therefore serves a double purpose: First, it closes the grain of the metal, and, secondly, it reduces the stock to a size and shape that are practical for the drop-hammer dies to handle with a minimum number of blows.

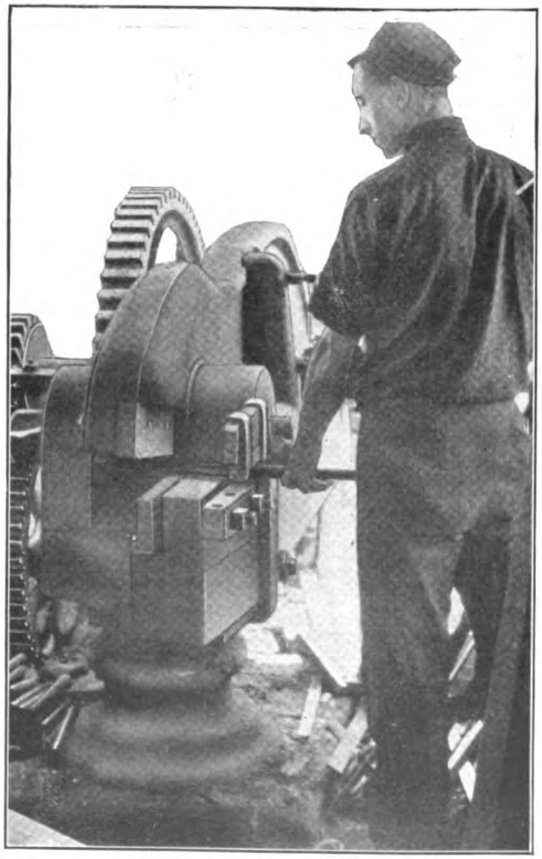

FIG. 4. THE BARS ARE FIRST SHEARED INTO 8-IN. LENGTHS

ging of the firebrick furnace lining is experienced when steam is used than when air is employed for vaporizing.

A number of blanks are kept heating in the furnace at the same time, one being put in each time that one is taken out, so that there is no delay through having to wait for blanks to reach a working heat. The tong hold, which is a square tit on one end of the blank, put on for the use of the drop-forge operator, is drawn first; then the hot blank is placed on an iron block and gripped on the tit end with a pair of tongs with jaws sufficiently long to reach the round stock beyond the tit, thus avoiding the necessity of changing tongs at this point. The blade is next drawn roughly to a tapered square section, the one pass through the dies being sufficient for this, the operator standing as shown in Fig. 5.

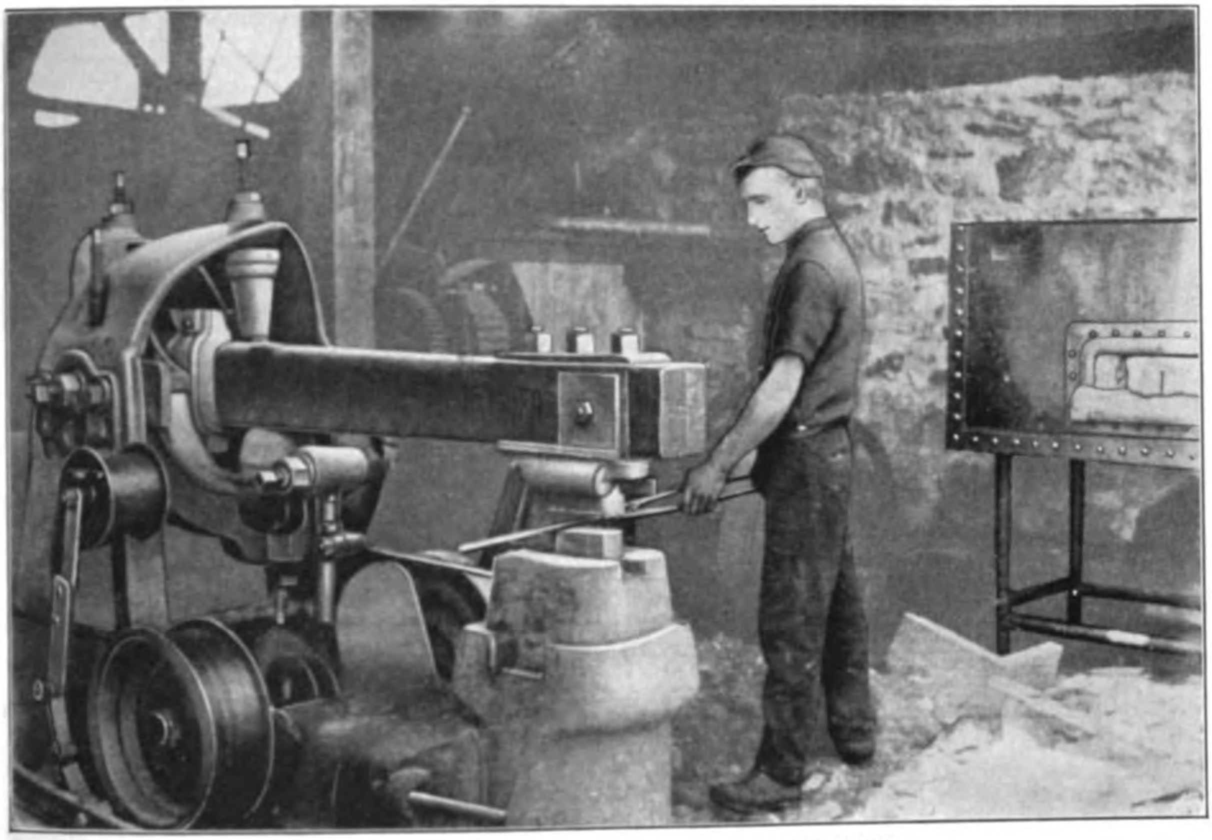

FIG. 5. DRAWING THE BLADE IN THE HELVE HAMMER

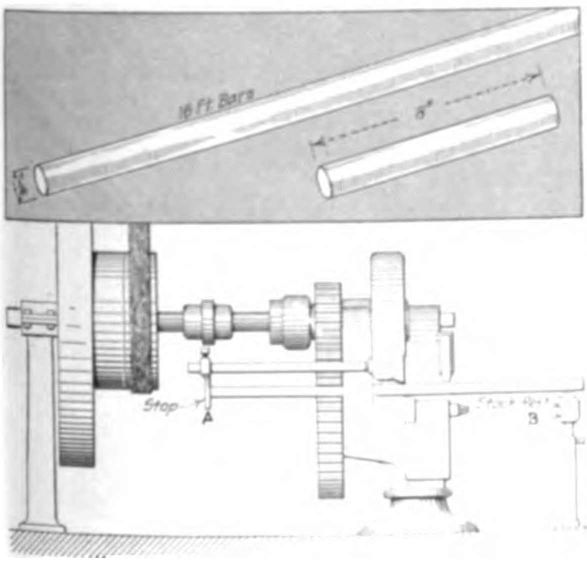

OPERATION 1. SHEAR TO 8-IN. LENGTHS

Machine Used—Alligator shear.
Special Tools and Fixtures—Length stop A for stock; [illegible] guide rest B for long bars.
Gages—None.
Production—From one operator and one machine, 700 to [illegible] pieces per hour.
Notes—Machine runs at 20 strokes per minute. The bars of 1½-in. alloy steel average 16 ft. in length.
Reference—See Fig. 4.

It takes a big drop hammer to make a bayonet forging. A 2,000-lb. board drop is employed on this work, and its massiveness is apparent from an inspection of Fig. 6. The weight of the base of this hammer, most of which is underground, is 30,000 lb., and the entire machine with die blocks must weigh close to 25 tons. The full drop of 4 ft. is not required on bayonet work, where the stock is roughed out so as not to leave too great a surplus of metal, and in this case three-quarters of the full length of drop is used.

The operator who looks after the drop forging is a busy man. Not only does he tend his heating furnace, but he also takes care of the edger and two impressions on the drop dies and operates the trimming press as well. All of this is done at one heat and necessitates quick and sure movements. The apparatus is arranged to conserve the motions of the operator as much as possible, the furnace and presses being within easy reach. In forging a bayonet the operator turns to the furnace, grips the heated piece in his tongs, holding it by the square tit, and swings it under the edger. It is shown there in position in Fig. 8, at *B*, ready for the hammer

to descend and make the bend for the hilt and also break down the blade to a taper. In actual work, the operator would retain his tong hold upon the piece during the edging and subsequent operations; but it was necessary to have him step out of the way so that the die might be clearly seen.

One blow is sufficient for edging, after which the piece is swung to the first impression, where a blow or two gives it the shape seen at *C*, Fig. 8. From here it is

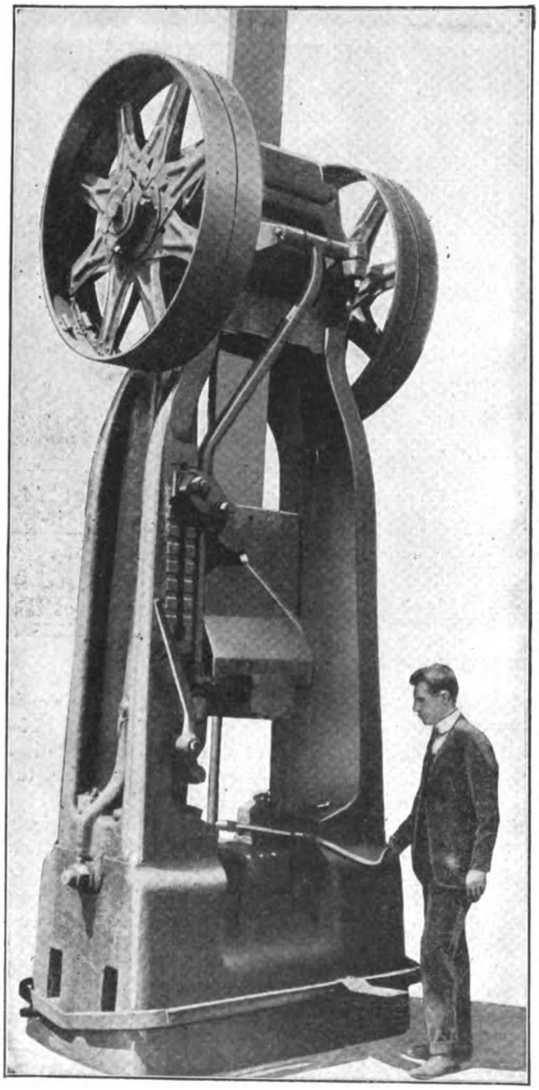

FIG. 6. IT TAKES A BIG DROP HAMMER TO MAKE A BAYONET FORGING

placed in the finishing impression and given one blow, which squares up the flash on the lower side of the forging, so that the piece will not rock when placed in the trimming dies, where it is next put by the operator. It is pushed through the lower trimming die, which is made open on the end, as illustrated in Fig. 10, so that the operator may still retain his hold upon the forging. As soon as it comes from this die, it is swung once more to the finishing impression, this time minus the flash, and is given one blow to correct the shape. The whole process does not require as long as it takes to read its description, as may be judged by the fact that the forging is still red hot after the final blow.

The drop-forge dies and the arrangement of impressions are shown in line drawing on the third operation

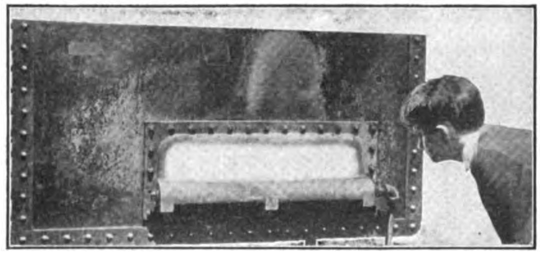

FIG. 7. THE SAFE FORGING HEAT FOR BAYONET STEEL IS BETWEEN 1,800 AND 2,000 DEG. F.

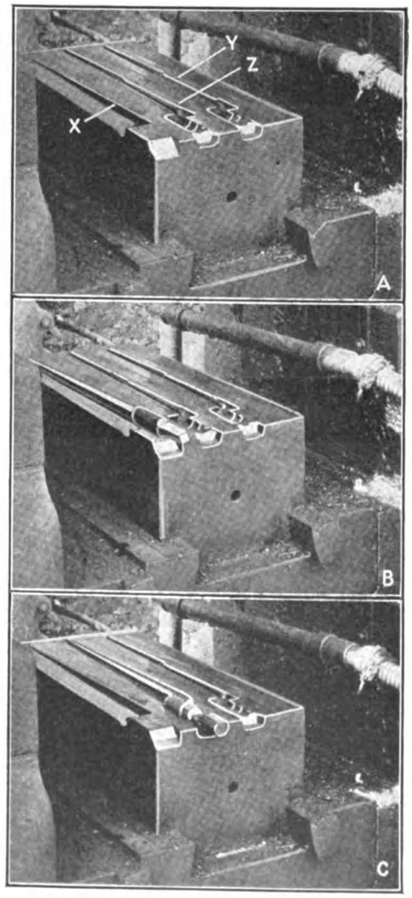

FIG. 8. THE LOWER DIE BLOCK OF THE DROP HAMMER WITH BAYONET IN POSITION

sheet. These dies are solid blocks of crucible steel having a carbon content of 90 points. There is little difference between the roughing and finishing impressions except in the matter of providing for the flash on the finishing impression. In the rougher the corners of the

impression are simply rounded, as shown in sections *AB* and *GH*. The lower finishing impression has a flash gutter milled around it, extending out some $\frac{3}{4}$ in., as in section *CD*. The upper finishing impression not only has this same flash space, but in addition has a land, $\frac{1}{8}$ in. wide, surrounding the outline, as indicated in section *EF*. This is for the purpose of thinning the flash and is omitted from the lower die block so that the flash may be flat on its lower surface and thus not be inclined to rock when placed in the trimming die. These dies were sunk by Hollender & Johnson, of Worcester, and the die blocks were furnished and afterward hardened by the Heppenstahl Forge Co. Hardening a 300-lb. die block of this kind is a fair sized job where the warp across a 23-in. face must be less than 0.003 in. It is done by immersing the block face down in a water bath, submerging the impression surface some 3 or 4 in. and having an air jet agitate the water beneath.

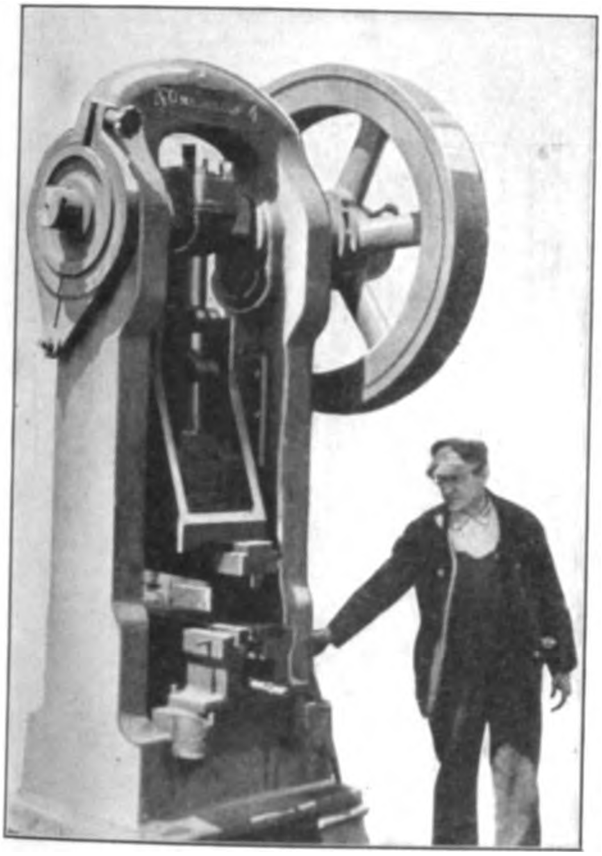

FIG. 9 THE "FLASH" IS TRIMMED WHILE THE BAYONET IS STILL HOT

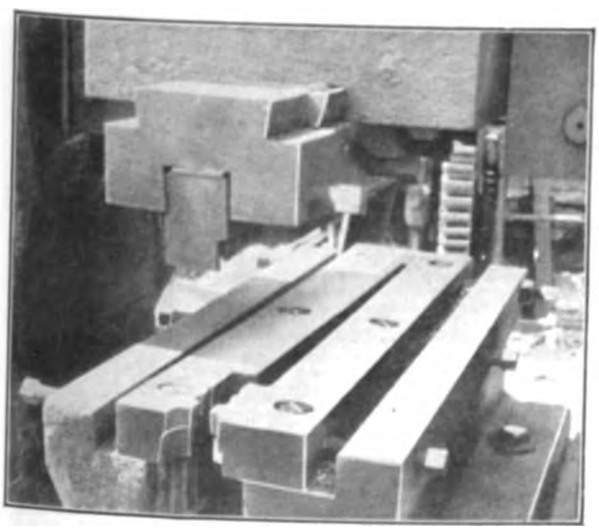

FIG. 10 PUSHING THE BAYONET THROUGH THIS TRIMMING DIE REMOVES THE FLASH

After the severe treatment it receives under the drop hammer, the metal in the bayonet forging becomes exceedingly brittle. This fact is used to advantage in breaking off the tong hold, which is the next operation after drop forging. The bayonet is held by the blade with the tong hold against the corner of an anvil, and a light tap with a hand hammer is sufficient to fracture the tong hold tit. This operation may be seen in Fig. 11.

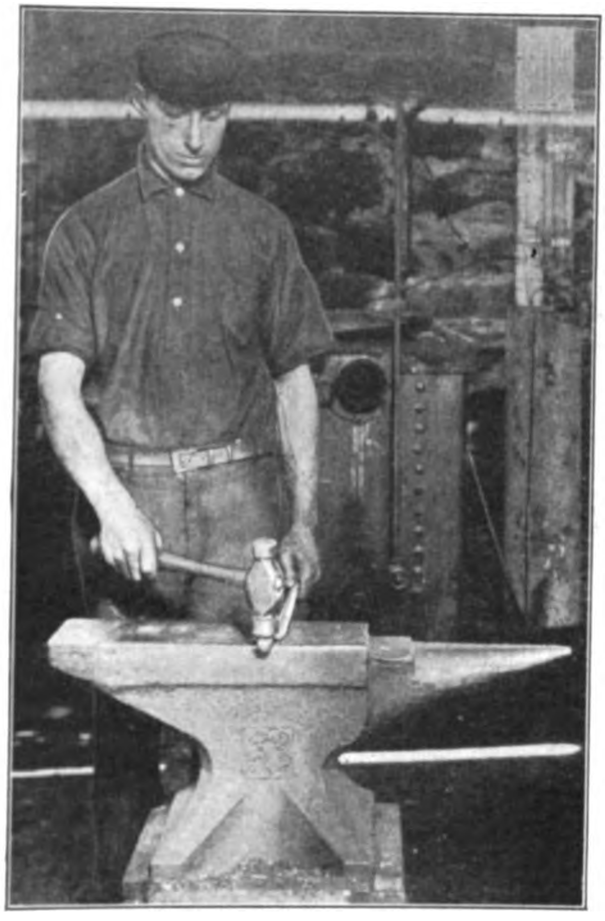

FIG. 11 A LIGHT TAP REMOVES THE TONG HOLD

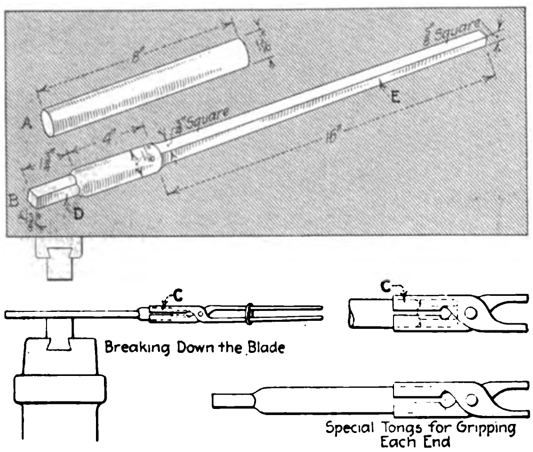
While brittleness was an advantage in the last operation, it is a disadvantage as far as the finished product is concerned and must be removed by annealing. The furnace for this purpose is shown in Fig. 12, and the pyrometers for controlling the temperature may also be seen at the right of this picture. Considerable time was spent by the Hankey company in determining the best form of annealing box for bayonet work; the outcome of their experiments was the use of a rather unusual form of box—an 8-in. steel steam pipe. Six of these pipe containers are placed in the furnace at one time after being filled with bayonets packed in an annealing mixture

consisting of spent charcoal and burnt coke. The pipes are sealed by means of caps and luting and are then brought to a temperature of 1,450 deg. F. in the oil-fired furnace. They are maintained at this temperature for a period of 10 hr., after which the heat is turned off and the furnace and pipes allowed to cool together—a process that takes place overnight. The resulting anneal is very complete, and the forgings are as soft and easy to cut as one can expect material of this chemical analysis to be.

In order to help the cutting tools of the machine shop as much as possible, whatever scale has been formed during forging and annealing is next removed by pickling. The bayonets are placed in wooden frames which are hung in the pickle tank—a wooden tank containing a 3 per cent. solution of sulphuric acid. Kept at the boiling point by means of a live-steam jet, this solution is wonderfully effective and does its work in a few moments. In fact, it would keep on working if not restrained, and for this reason the bayonets are transferred to a washing tank and thence to a neutralizing bath consisting of hot lime water. This use of hot solutions instead of cold ones is a time saver that is overlooked in a great many shops, and I do not know of any place where steam can earn its keep more easily than when put at this kind of work.

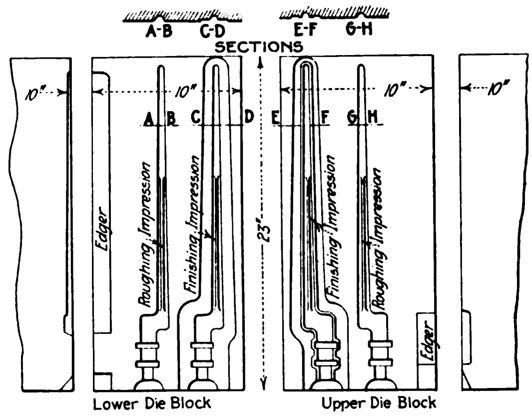
When the bayonets which have been thus treated are not to be machined for some time, they are placed in a steam-heated oven and baked for several hours in order to make sure that the action of the acid has been completely stopped. The inspection of a finished bayonet for smoothness and freedom from pits and scratches is gone about in a most thorough way and is really a critical one, as over-etching due to the acid of the pickle may cause rejections later on.

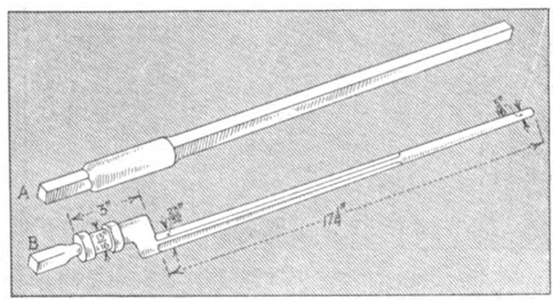
In spite of the comparatively small safe range of forging heat and the remarkably fast production time made on these bayonets the percentage of loss is small, running up to the present at less than 1 per cent. It would seem from these considerations that this process of forging the butt and the blade in one piece is not only conducive to a stronger job than that produced by welding the two, as is sometimes done, but also is considerably less expensive.



OPERATION 2: DRAW TONG HOLD AND BLADE

Equipment Used—Bradley 100-lb. cushion helve hammer; Kenworthy overfired muffle furnace.
Special Tools and Fixtures—Tongs C for gripping both ends of the stock.
Gages—None, although at first the operator used a steel rod to determine the amount of draw.
Production—One operator, tending the furnace and running the hammer, produces 80 pieces per hour, drawing both tong hold and blade.
Note—The stock is first gripped in the tongs, and the square tong hold D is drawn. The piece is then laid on a block, the tongs are transferred to the opposite end, after which the blade E is drawn in one pass between the hammer dies, the operator turning the stock 90 deg. between each blow. One heat serves for both draws. The forging temperature is between 1,800 and 2,000 deg. F.
References—See Fig. 2, B and C, and Fig. 5.





OPERATION 3: DROP FORGE AND TRIM

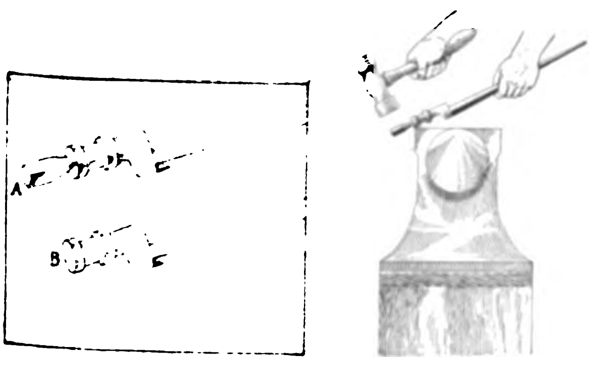
Equipment Used—Kenworthy overfired muffle furnace; Billings & Spencer model D 2,000-lb. drop hammer; Massillon No. 4 trimming press.
Special Tools and Fixtures—Drop-forging dies, trimming dies and a pair of tongs (not shown).
Gages—None used.
Production—One operator, tending the furnace and running both the drop hammer and the trimming press, produces 100 finished forgings per hour.
Notes—The stock, heated in the furnace (1), is gripped with the tongs and transferred to the "edger" (2), where it is bent and broken down with one blow. Then it is transferred to the roughing impression (3) and given one or two blows as required. It is next given one blow in the finishing impression (4) to square up the flash, after which it is swung to the trimming dies (5), and thence is put once more into the finishing impression for a final blow. The operator holds fast to the tongs during all the blows. The forging temperature for this operation is between 1,800 and 2,000 deg. F.
References—See Fig. 2, D, E and F, and Figs. 6, 7, 8, 9 and 10.

It is interesting to notice that the cruciform type of bayonet is used not only by the Russian army, but also to a large extent by the French. The Russians fasten their bayonets permanently to their rifles and use no scabbards, while the French make theirs demountable and provide them with short handles so that they may serve as close-quarter rapiers.

As far as a comparison between the two forms of bayonets—the cruciform type and the saber-blade type—

is concerned, there is not much to choose if one must be pierced by either; as a manufacturing proposition, however, the cruciform type appears to have more reasonable test requirements and more commonsense limits, both of which items are warmly appreciated in any machine shop that desires to show a profit.

FIG. 12. THE ANNEALING TEMPERATURE IS CLOSELY CONTROLLED BY PYROMETERS

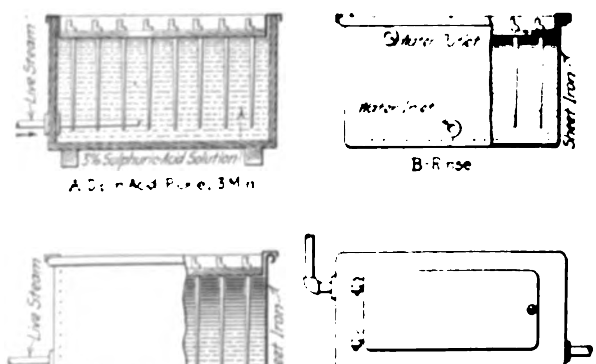


OPERATION 4. BREAK OFF THE TONG HOLD

Equipment Used—Hand hammer and anvil.
Production—From one operator, 400 to 500 per hour.
Note—The stock is very brittle after drop forging and before annealing, therefore the tong hold may be snapped off with a light blow.
Reference—See Fig. 11.

OPERATION 5. ANNEAL

Equipment Used—Kenworthy oversized oil-burning muffle furnace, 8-in. steam pipes for bayonet containers.
Gages—Pyrometers.
Production—Each container or packing box holds 50 bayonets, and six of these are annealed in a heat, giving a production of 300 blades in 24 hr. from one furnace. Operator's time averages 4 hr. per heat.
Notes—The annealing temperature of 1,450 deg. F. is maintained for 10 hr., after which the furnace and containers are allowed to cool during the night. A mixture of spent charcoal and burnt bone is used as an annealing material.
Reference—See Fig. 12.



A. Dip in Acid Pickle, 3 Min.   B. Rinse
C. Neutralize in Hot Lime Water, 3 Min.   D. Bake in Oven 2 Hours at 350° F. to Drive off remaining Acid

OPERATION 6. PICKLE, WASH, NEUTRALIZE AND BAKE IN STEAM-HEATED OVEN

Equipment Used—Pickle tank, washing tank, neutralizing tank and steam-heated oven, perforated wood dipping-boxes.

Gages—Hydrometer for testing strength of acid solution.

Production—Two men can care for all of the operations previously outlined for an average of 400 bayonets per hour.

Notes—The pickling solution is a 3 per cent. solution of sulphuric acid. This is maintained at the boiling point by the injection of live steam. The neutralizing solution is hot lime water. The baking oven is maintained at a temperature of 300 to 350 deg. F. by steam coils. The sequence of operations is in the order given. If the bayonets are to be polished immediately, baking is dispensed with, the machining operations removing the acid.

Finding the Financial Basis of Special Tools

By Dexter S. Kimball*

Though much has been written on the use of special tools in manufacturing processes, there are certain principles governing the economical use of such implements that are not always fully appreciated or understood. Of course, the economic principles involved in the use of special tools are the same as those underlying the use of labor-saving apparatus of any kind. But the facts that these tools are usually made for a specific purpose and that they are in general short-lived necessitate special consideration of the method of defraying their cost.

Standard tools, so called, that can be used for a variety of operations on many kinds of product can be installed with some assurance that they will be useful over a long period of time. There are therefore opportunity and justification for recovering their initial cost by depreciation methods from the profits made on all lines of product in which they are used. It should be noted, however that this may be true also of special tools, so called. A tool may have a very limited range; but if there is assurance that it will be useful over a long period and for a large amount of product, it can be treated financially in the same manner as a standard tool. For the purpose in hand it is indeed a standard tool, and in mass production of specialized product many such machines are to be found. The true distinguishing feature, therefore, is not the character of the work to be performed, but the amount of service that the tool is likely to render. Obviously these limitations are not always very clear, and for this reason the true effect of special tools in reducing productive costs is not always fully understood or applied. The following discussion deals with the problem of special tools that are short-lived or which are used for a limited amount of product.

Special tools such as jigs and fixtures may be made for one of two reasons—namely, to insure accuracy in the product or to reduce the cost of production. Sometimes both results are desirable or necessary. If accuracy in the product is imperative, the question of cost may be a secondary consideration. Thus it may be necessary to manufacture on the interchangeable system without regard to cost, and special tools might increase rather than lessen the cost if the quantity to be produced is limited.

In many instances, however, special tools are resorted to for the purpose of reducing cost, accuracy and duplication of form appearing as secondary advantages. In either case it should be remembered that the special tools must be paid for.

Special Tools Often Made with Vague Idea That They Reduce Cost

In many shops special tools are "just made" without much consideration of the financial principles governing this economic use, but with a vague idea that they will reduce cost. Only too often they are discarded after a short period and long before they have paid for themselves. This is particularly likely to happen where the cost of special tools is carried as an asset on the theory that the interest on the investment that they represent will be more than recovered in the reduction in cost that they effect. Standard tools may be treated in this manner with safety, but special tools, which are essentially short-lived, present a different problem. It is possible, of course, to carry special tools as assets and by liberal depreciation recover their cost through the sales. But this is seldom done intelligently, and often there is no assurance that this depreciation is recovered from the sales of product made with these special tools or from profits made on other articles. In many cases little or no depreciation is charged against special tools; and they remain a hypothetical asset, though really they are worthless and a monument to unintelligent management.

An accurate consideration of special tools must take cognizance of the quantity to be manufactured; and the only safe way to treat special tools is to insure, if possible, that their cost is "buried" in the cost of a definite number of operations, even though this number may be somewhat arbitrarily chosen. The general principles can best be illustrated by a concrete example.

An Example Showing Importance of Quantity

Suppose the labor cost of doing a certain operation on standard tools is \$1, and that by the method of burden distribution in use the burden is one-half the labor cost. Suppose that by making a special tool worth \$36 the labor cost can be reduced to 40c. Then the labor and burden cost for the first case will be \$1.50 and for the second 60c.,

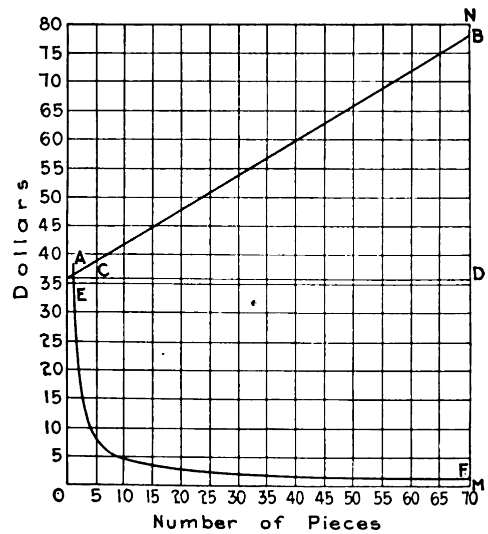


DIAGRAM OF RELATION BETWEEN UNIT COSTS AND QUANTITIES PRODUCED

or a gain of 90c. per piece by using the special tool. The cost of each piece (aside from the material) will be $\frac{36 + (0.60N)}{N}$, where N is the number of pieces made. Since the gain per piece is 90c., it will take $\frac{36}{0.90}$, or 40 pieces, to just pay for the tool; and if exactly this number is made, the unit cost will be \$1.50, or the same as with standard tools. If more than this number is made, the unit cost will be less than \$1.50; and if a lesser number is made, the cost will exceed this amount and the special tool will be the cause of a loss. The importance of some

*Professor of Machine Design and Construction, Sibley College, Cornell University.

knowledge of the number of pieces to be made, even though it be based upon an estimate, is therefore obvious.

These relations are shown graphically plotted. The fixed cost of the tool ($36) is shown by the line *CD*. The total cost of any number of pieces (neglecting material cost) up to 70 pieces is shown by the vertical ordinate of the line *AB*. Thus, for instance, the total cost of 70 pieces is made up of *MD* + *DB*, or $36 + (70 × 0.60). The unit costs are shown by the curve *EF*, and this curve is both interesting and important. It will be noticed that the curve falls very rapidly at first, the greatest gain in unit cost occurring when two pieces are made instead of one and a decreasing advantage being obtained as the number is increased. Thus the unit cost of one piece is $36.60, the unit cost of two pieces is $18.60, the unit cost of five pieces is $7.80 and of 10 pieces $4.20. At 40 pieces the cost has dropped to $1.50, or the same as the cost with standard tools, and beyond 60 or 70 pieces the gain in unit cost is not nearly so marked as in the beginning. Thus the unit cost of 70 pieces is $1.11, while the unit cost of 100 pieces is 96c. and of 1,000 pieces 63.6c. Up to the point where the cost of the special tool is equal to the total labor cost, the cost of the tool is the predominating factor in the unit cost. This situation occurs in this example at 60 pieces. Beyond this point the total labor cost is the predominating factor in unit cost. Thus at 1,000 pieces only 3.6c. need be added to care for the cost of the tool.

Two Important Points

Two important points appear from the foregoing discussion. While this discussion is based on the use of special tools, it should be observed that the argument applies to all kinds of work that are of the nature of preparation or preplanning. The question whether any preparatory work will pay can be answered only through a careful consideration of the quantity to be produced. This statement holds for special tools, patterns, drawings, engineering experimental work, clerical work and all the preplanning features of scientific management, so called. If large quantities are to be made, elaborate preparation can also be made with a resulting decrease in cost.

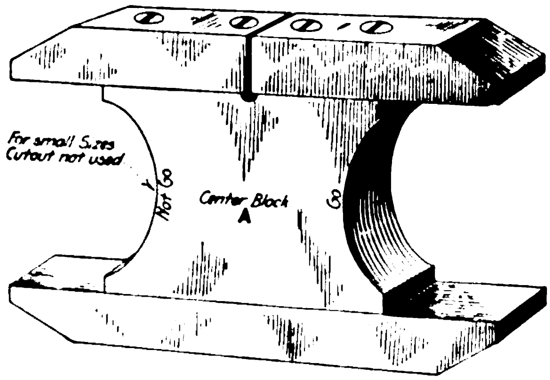
It sometimes occurs, however, that the work of preparation is not permanent and cannot be used again, once the job is finished. Thus the work of preparing a machine, finding clamps and bolts, adjusting fixtures and "getting the job in mind" is usually repeated every time the job is repeated. A brief study of the curve *EF* will show that great gains can be made by doing as many pieces as possible at one preparation, particularly where the number is small. The diagram data were taken at random, but are probable, and the great gain shown by doing even two or three pieces instead of one at each setting is true of nearly all productive processes. The small manufacturer in particular can profit greatly by having a full knowledge of these relations.

Accurate treatment of the finance of special tools is greatly facilitated by the use of a plant ledger ruled especially for this purpose. As the costs of successive jobs are posted up, the allowance or charge for the use of the tool can be included in the costs and entered in the proper account in the cost ledger, thus depreciating the tool till paid for. The plant ledger shows readily also the amount that has been invested in such special tools and indicates what must be charged off as interest on this investment.

Adjustable Snap Gage

By M. S. Henry

The usual form of solid snap gage is expensive to manufacture as well as difficult to keep to size. The accompanying sketch shows a gage which I think has many



ADJUSTABLE SNAP GAGE

advantages. It is not new, but deserves to be better known.

The center block *A* is ground to the maximum and minimum dimensions, the step being on one edge only. The finger pieces are screwed securely to *A*. When the fingers become worn, they are removed and ground on the inner surface and replaced, making the gage again as good as new. The center *A* always retains its original size.

Experience with Shop Signals

By H. V. Haight

The following experience with shop signals may be of interest to readers of the *Machinist* who are considering the installation of devices of this kind:

In our shop we tried both automobile horns and an 8-in. electric gong, but did not find that either of them could be heard very well more than 100 ft. away. We got a good suggestion from the Canadian Pacific Ry. shops in Montreal, to the effect that they were using locomotive whistles with electrically operated valves controlled from the timekeeper's office. It was stated that these whistles could be heard distinctly all over the shop, which is over 1,200 ft. long. We found, however, that the electrically controlled valves were an expensive proposition and as an experiment put in a 1-in. pipe line direct from the power house with a 2½-in. short bell whistle at the end of it. There is a quick-opening valve in the power house. The whistle can be heard very plainly all over the shop, which is 200x325 ft. The whole equipment is very simple and satisfactory.

I have a theory that both the gong and the automobile horn make a noise so much like the ordinary noise of the machine shop that they cannot be readily distinguished. A similar experience with an alarm for a thread miller confirms this belief. The alarm was used to give warning before the spindle reached the end of the travel, to prevent a smash. I arranged a small, mechanically operated gong that made a great noise in the store where I bought it; but after it was installed in the shop, it could hardly be heard 10 ft. away. I think I will try a little compressed-air whistle on the next machine.

Turret-Lathe Fixtures for Textile-Machine Details

By Robert Mawson

SYNOPSIS—The fixtures here shown and described were designed and used on Jones & Lamson flat-turret lathes. They are somewhat simple in their construction, but produce parts accurately and quickly. In two of them an expanding arbor is used to locate and hold the pieces securely.

Herewith are illustrated some of the fixtures used by the Hemphill Manufacturing Co., Pawtucket, R. I., in machining textile-machine details. On page 852 other similar fixtures were shown and described. The fixtures are designed so that the parts may be easily placed in position and held quickly and rigidly. The tools are giving the best of satisfaction, producing parts quickly and accurately.

In the fixture used in performing the first machining operation on the stitch ring the rough casting is placed on three pins. Three setscrews are tightened against the casting to hold it securely.

The location pins may be slid into several positions afterward, being held by screws. This arrangement enables one fixture to take care of various diameters of stitch rings. When the casting is held securely in position, the inside is bored to size. For the second operation the stitch ring is placed on a turned arbor. The nut on the outside of the fixture is then tightened. The pressure exerted by the bolt forces out expansion jaws which, coming against the stitch ring, hold it securely. The various surfaces mentioned are then turned and faced.

The fixture used in machining the 26-tooth gears is provided with a tapered surface inside of which the casting is placed. A plate is put over the tapered surface, and by tightening the three screws shown the plate is forced down. As the pressure is applied, chuck jaws are forced in against the casting, thus locating it centrally and holding it securely for the machining operation.

In machining the fashion wheel the casting is located by a turned stud that fits into a previously bored hole. After the casting is in position, the washer and thumb-nut shown are tightened, holding the part in position. The surfaces mentioned are then machined.

The various fixtures are provided with a turned shoulder that fits accurately into a recess of the faceplate of the Jones & Lamson turret lathe. After the fixture has been placed in position, three setscrews tightened into tapped holes of the fixture hold it securely on the machine. It will be observed that the fixtures illustrated are somewhat simple in their construction, yet strong and rugged.

After the fixture is once in position on the machine, it is a comparatively simple operation to place the casting for the machining operation. Gages are used to test the machined surfaces, so that accurate results may be obtained. Good rates of production, given herewith, are obtained with these fixtures. Similar fixtures could be easily designed for and used on other types of tools.

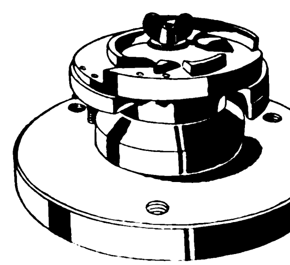


FIG. 8. FIXTURE FOR MACHINING FASHION WHEEL

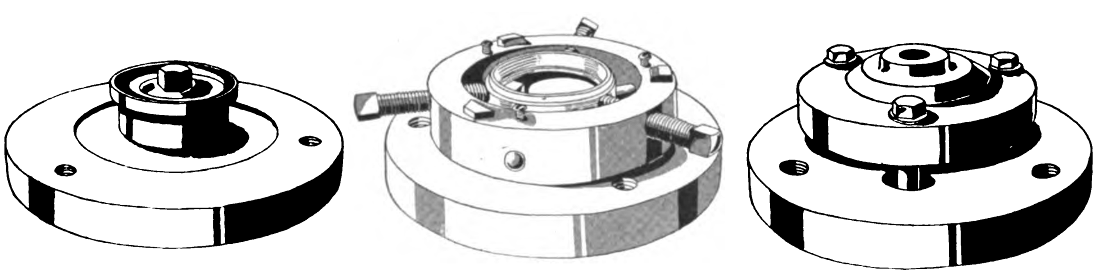


FIGS. 2, 4 AND 6. TURRET-LATHE FIXTURES FOR MAKING TEXTILE-MACHINE DETAILS

FIGS. 2 AND 2-A

Operation—Second machining of stitch ring, Fig. 1. The casting is placed on a turned arbor that fits into a previously bored hole. The center bolt is tightened, which expands the arbor, thus holding the piece securely.

Surfaces Machined—The outside turned, the edges faced and the beveled surface machined.

FIGS. 4 AND 4-A

Operation—First machining of stitch ring, Fig. 3. The rough casting is placed on three pins, and the setscrews, being tightened against the piece, hold it securely.

Surfaces Machined—Hole bored and recess faced.

FIGS. 6 AND 6-A

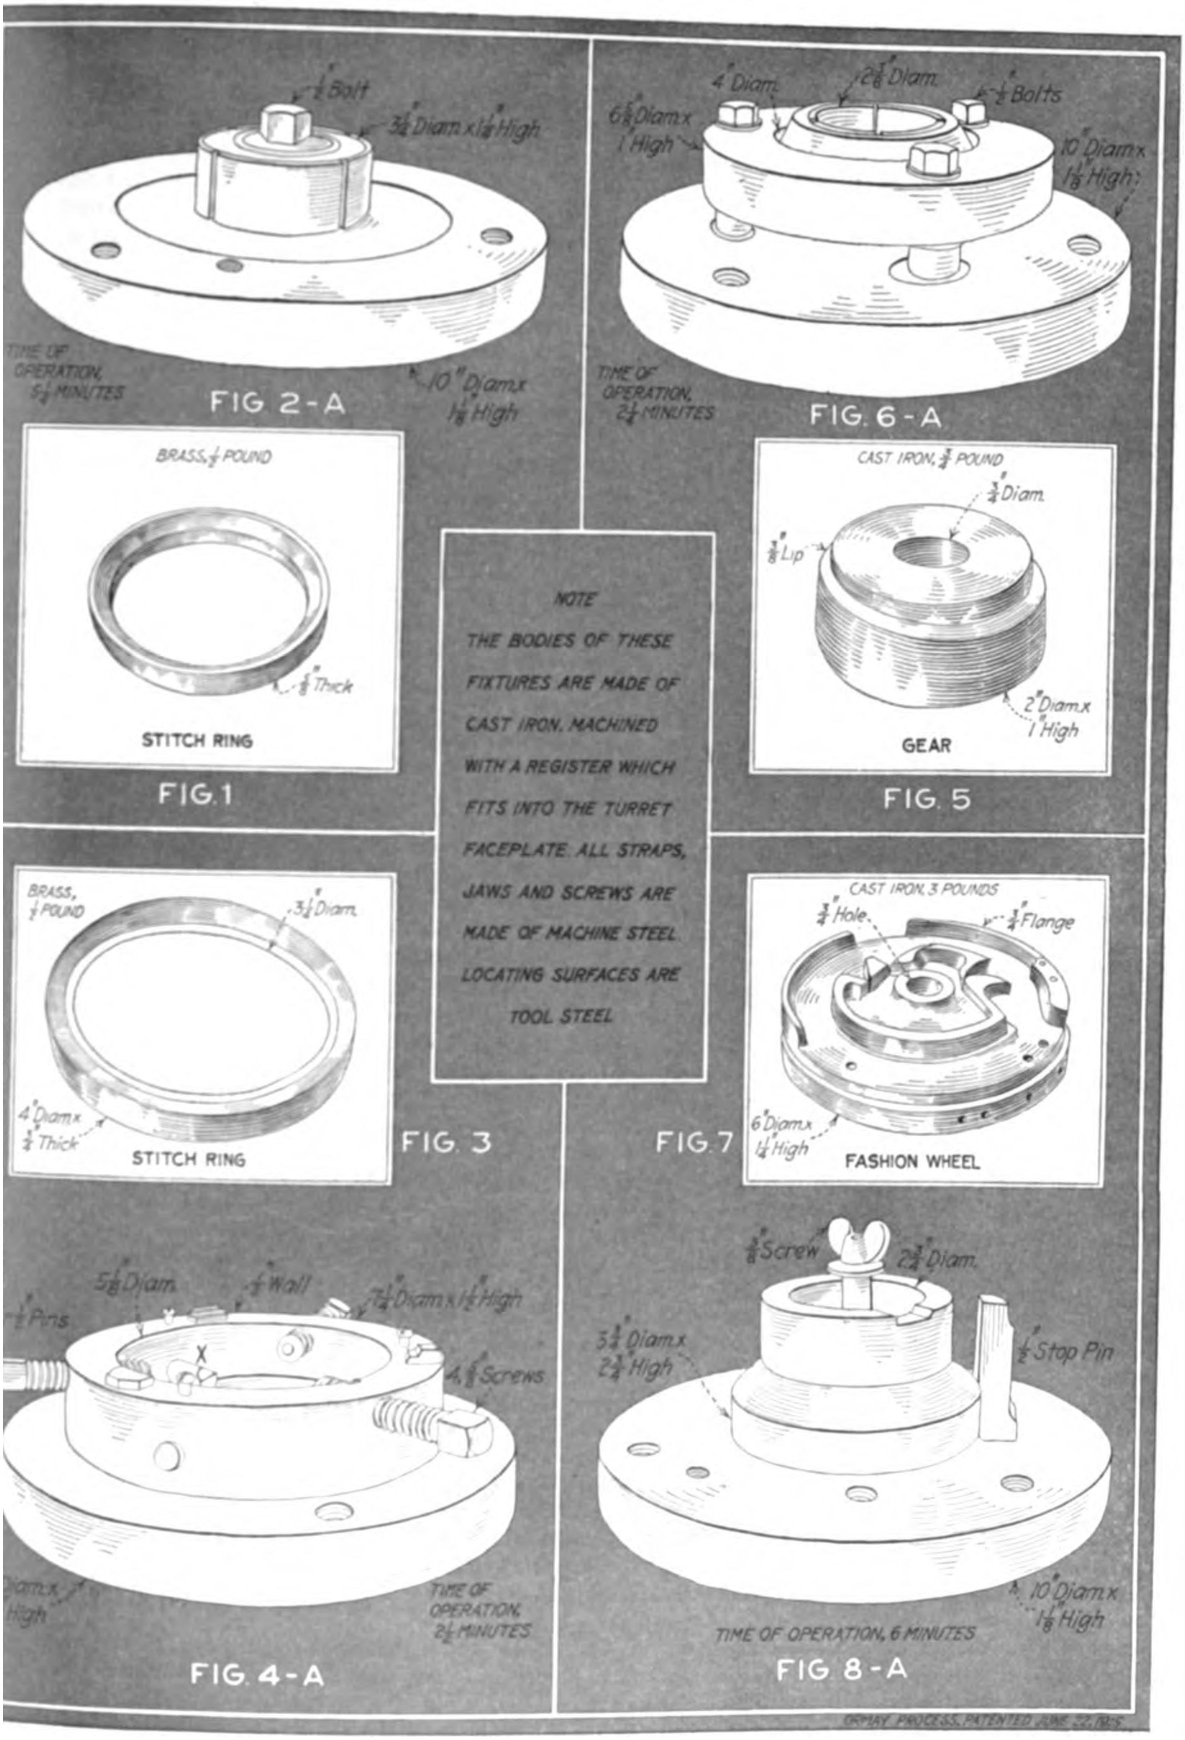
Operation—Machining 26-tooth gear, Fig. 5. The turned blank is slid into the fixture, and the three screws, being tightened, push down the plate on a tapered surface, forcing in the chuck jaws against the gear and holding it securely.

Surfaces Machined—Recess turned, shoulder faced and end surface turned.

FIGS. 8 AND 8-A

Operation—Machining fashion wheel, Fig. 7. The casting is located on a stud that fits into a previously bored hole. The washer and thumb-nut, being tightened against the piece, hold it securely.

Surfaces Machined—Outside turned and shoulder faced.



TURRET-LATHE FIXTURES FOR TEXTILE-MACHINE PARTS

Russian Trade After the War

By R. Martens*

Russia after the war is going to be a far different country, and the trading with that country after the war is going to be far different, owing principally to the fact that the Russian populace, by tens of millions, have received an extraordinary education. The Russian peasants have been drawn far from their home surroundings by the war, which have been unchanged for generations. They have had the opportunity of seeing new sections of Russia, new conditions and new cities. They have seen trench diggers, motor cars, field kitchens, machinery, tools and all sorts of appliances which are used in modern warfare.

The Russian prisoners in Germany and Austria, it is understood, are utilized by those respective governments in building railroads, bridges and canals, and in the construction of towns. The large number of German and Austrian prisoners which are detained in concentration camps at some points, or which, in the case of those in Siberia, are allowed considerable freedom, out of sheer monotony are inclined to teach the Russian peasants the latest methods of cultivating the soil and obtaining the greatest results from the vast but dormant possibilities of the Russian farm land. Hundreds of thousands of wounded have been taken care of in the cities, and when convalescent have had the opportunity of seeing railroads, modern shops, sanitation systems and all of the latest improvements and devices which are a part of a highly civilized community, all of which, before the war, they had never even heard of. These things have left a lasting impression on their minds, for the mind of the Russian peasant is a mind that has extraordinary powers of observation, assimilation and imitation.

It should be further remembered that the sale of vodka has been abolished in Russia and that hundreds of millions of dollars have thereby been saved which would otherwise have been wasted. At the same time, the working capacity of the people has accordingly increased, from the standpoints of efficiency, quality and output. Furthermore, a considerably larger number have been employed in factories and in other constructive work at very good wages, in fact, at wages ranging from two to ten times as high as they have ever received before, with the result that more money is in circulation than has been the case for almost a generation. The populace at large has grown to be richer and the increased wealth is shown by the extraordinary rate of increase in the deposits in the savings banks.

The people are accordingly in a position to purchase small machinery, tools and various comforts which before the war they did not know existed or could not afford to buy. Therefore, it is my contention that the trade after the war will be entirely different from the trade before the war. For every one buyer we had before the war, we will have a hundred buyers after the war. Before the war, there were only certain classes of people who were in a position to buy. For the first time in history a large proportion has a considerable spending capacity.

The war has undoubtedly cost the Russian government a vast sum, but considering that just before the war the national indebtedness of the country was hardly \$25 a head and that it is computed that if the war should last until the end of the year the indebtedness would be only \$50 a head, it will be seen that the debt imposed upon the populace by the war is trivial when compared with the greatly increased buying capacity and with the enormous natural wealth of this vast empire. The spending capacity of the people has not only been increased, but they have at the same time been educated and have learned how to make the land yield more wealth than it has ever yielded before.

Another important difference which will be seen between the trade during the war and the trade after the war is this: The business which is being done now is of a destructive and not of a constructive nature. After the war all this will be changed. Therefore, you business men of America must not consider that the enormous export business which is being done now is genuine business. The product you are now exporting is for purposes of destruction and not of construction, and I want to make this point very strong. Before the war you scarcely heard of Russia, except, perhaps, that the bears walked about in the streets in that country. The war has brought Russia to the front through the millions of dollars which American manufacturers have made on the manufacture of munitions of war.

I want to bring to your attention the fact that this business is financed by the Russian government, and that the product you are shipping is for the use of the government and in very few instances for the use of the populace. I warn you to consider this point very carefully. You talk in this country about preparedness. I agree with you that preparedness is wise, but it is the preparedness for trade which is one of the strongest assets of any nation. By preparedness for trade I mean not immediate selling but the studying of the people where you are going to trade, of their languages, characteristics and the climatic conditions. I want you to realize that Russia has climates ranging from the climate of Greenland to the climate of Cuba and that the trading conditions in the various intermediate climates are different in each case. This vast empire is five times as big as the United States and the trading conditions which must be met are very wide.

Again, I ask you to specialize. Machinery of all kinds is becoming more and more complicated and requires specialists in every line. If you are a manufacturer of motor cars or a manufacturer of wood-working machinery, you select a man to represent you, as a salesman or engineer, who has the best knowledge of the talking points of the machine you have to offer. How far more important it is that you should do the same in an undeveloped country like Russia! You must remember that there will be hundreds of men, representing all countries, who have machines similar to yours to sell, and that the man who is going to get the business is the man who can best talk and demonstrate the selling points of his machine. You must specialize, because there the classes of merchandise are kept much more distinct, and an engineer in Russia will not buy machinery from a firm that sells also watches or typewriters.

Do not offend the Russian buyer by adopting methods of trade that would not be successful in this country. The Russian buyer must not be confused with the buyers in certain parts of the far East where merchandise can be sold regardless of fitness or quality. Russia, especially among the engineering classies, is highly civilized.

*Address before the National Export and Import Association, Chicago.

Automatic Manufacturing Miller with Receding Table

SYNOPSIS—In the development of the machine described in this article an intimate knowledge of the requirements of gun-part and similar manufacture was brought to bear. The proportioning of the parts takes care of an extra-large factor of safety, and there is provided a flexible automatic control of the table through the feed unit. The distinctive feature is the receding table, through which cutter marring of the work on the return travel has been eliminated.

The illustrations show front and rear views of the new Pratt & Whitney automatic miller. The story of the development and marketing of this machine is probably the most remarkable and interesting one of its kind the world has ever known. Some time in the early summer of 1914, a foreign representative of the Pratt & Whitney Co. cabled to Mr. Hanson somewhat to this effect: "Please let me have some talking points which will enable me to persuade buyers to pay from one to two hundred dollars more for a Pratt & Whitney Lincoln miller than they have to pay for copies of it made here." As externally the competing machines were duplicates of the Pratt & Whitney Lincoln miller, it was no easy matter to supply "talking points" which would weigh from "one to two hundred dollars" in favor of the genuine machine. Obviously the only thing to do was to furnish a machine which would produce the same work or more in such a manner and at an operating cost that would make comparison with other machines the deciding factor in its favor. At the time he received the cablegram Mr. Hanson, by a peculiar coincidence, happened to be scheming out the preliminary requirements of the automatic miller, but nothing in the way of a complete drawing or even sketch had so far been made.

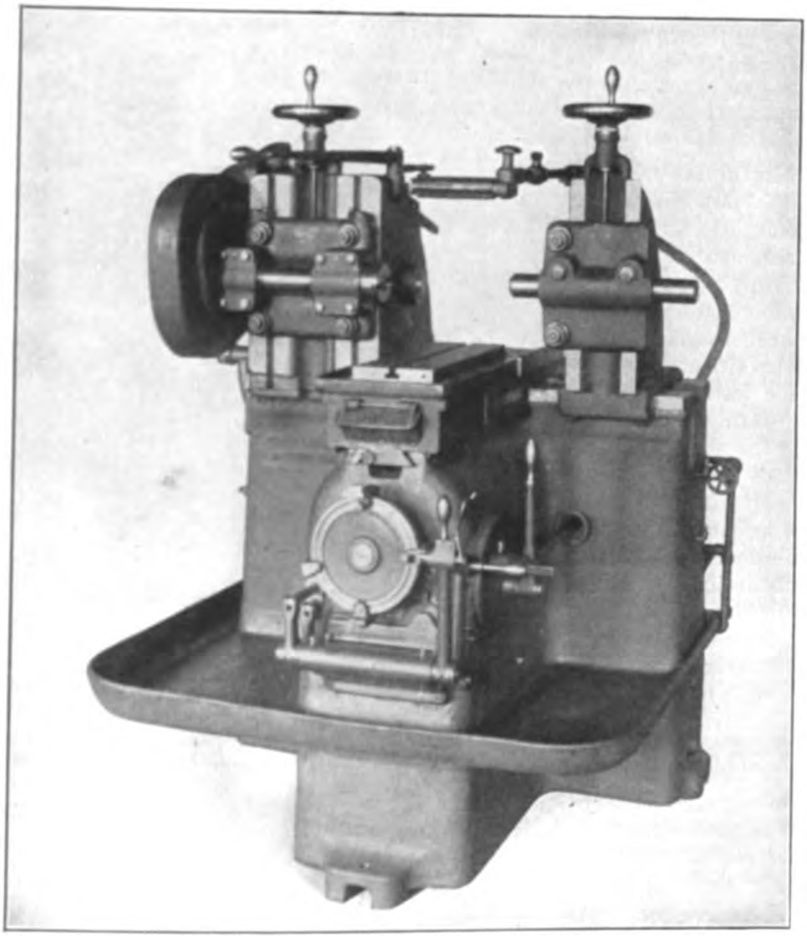


FIG. 1. FRONT VIEW OF AUTOMATIC MILLING MACHINE WITH RECEDING TABLE

With an intimate knowledge of the requirements necessary for gun parts and similar manufacture, preliminary sketches were quickly made of the mechanisms necessary to carry and rotate the spindle, actuate the table and so forth. With these completed, it was a comparatively simple matter to sketch out the approximate external appearance of a machine necessary to house these components. From this sketch a drawing was made which, after slight correction and alteration here and there, furnished the basis for a wash drawing. Photographs of this were then prepared and forwarded, together with specifications.

The foregoing, except as an illustration of rapid thought and work, is nothing remarkable. The remarkable part is that the photographs of a wash drawing of a thought, when reinforced by the Pratt & Whitney reputation, were the means of selling over a thousand automatic millers before even the model machine was completed. Except for a few minor changes the machines being built today are duplicates of the first one which left the factory in Hartford, Conn., early in November, 1914. At this writing, just one year and a half after the first machine was completed, there are 3,000 of these automatic millers at work producing parts of firearms and milled work of a similar character. In the development of the machine the object has been to produce a distinctive manufacturing tool, better adapted to the diversified requirements of manufacturing milling than any machine that has hitherto been available for this purpose.

The automatic miller is of massive construction throughout. In proportioning the various components a margin of safety has been adopted far in excess of what

has been previously considered necessary for a machine to handle work of this type.

The table has a working surface $6\frac{1}{2}$ in. wide by 18 in. long. It is traveled directly in the bed, thus eliminating the additional saddle joint which has proved so destructive to the stability of millers in general.

The table and bed bearing surfaces are of equal length, which is inducive of uniform wear. Proper relation between these bearing surfaces is easily maintained by means of a taper gib.

The travel of the table is 12 in. In addition to a wide range of working feeds the table is provided with rapid traverse in either direction. The rapid traverse is constant. The regular feed variations are obtained through change gearing and are independent of the spindle speeds. The rapid traverse, as well as the regular feeds, is actuated through a feeding mechanism of an entirely new construction, in which a heavily proportioned and powerfully driven cam is utilized. The feed unit is of substantial design throughout, and the movable members that are subject to wear are submerged in oil.

The automatic control of the table through the feed unit is very flexible. The regular feeds, as well as the rapid traverse, are automatically engaged by means of trip dogs. The dog plate upon which the dogs are carried is directly in front of the machine in a most accessible position. Provision is also made for traversing the table by hand when setting the machine.

With the feed control in operation, the work approaches the cutter on the forward rapid traverse, the regular working feed being automatically engaged, as the cutter is about to begin its work. After the milling operation has been performed, the return rapid traverse becomes automatically operative and the table is quickly removed to the original position for reloading. The return travel is such as to eliminate the possibility of the operator's being injured by coming into contact with the cutter. When the cut is intermittent—that is to say, not continuous—the rapid traverse is utilized for quickly passing over the noncutting space, the regular working feed being engaged as the cut is again approached. It can readily be seen that the table thus controlled reduces the nonoperating time of the machine to a minimum and that by doing away with the usual hand-operated return the machines are run with the least physical exertion by the operator. Practically the only function of the operator is to place and remove the work from the machine. Experience has demonstrated that one man can take care of from six to eight machines, depending on the character of the work.

The receding table is an entirely new device by means of which the objectionable feature of the cutter marring the work on the return travel has been completely eliminated. This device is so constructed that, after the milling operation has been performed, the table recedes or drops away from the cutter, thus permitting the work to clear the cutter on the return travel. As the table approaches the end of the return stroke where the work is clear of the cutter, the table is again elevated to its former position—the working height.

The functions of the table in this particular are automatically controlled. While this table has the advantage of not marring the work on the return stroke, the construction is such that this feature has been obtained without sacrificing the accuracy or rigidity of the nonreceding table.

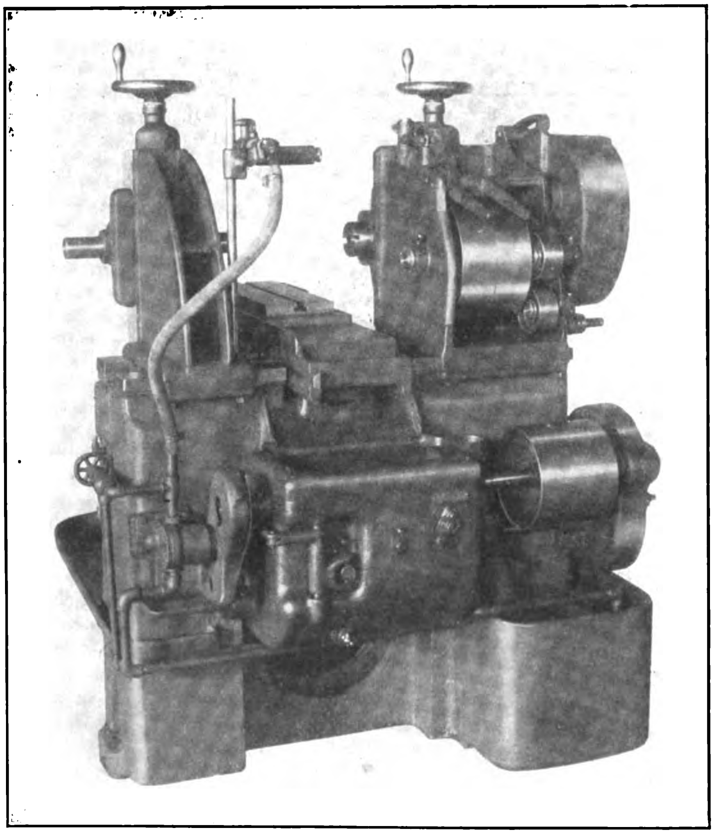

FIG. 2. REAR VIEW OF THE AUTOMATIC MILLING MACHINE SHOWING DRIVING MECHANISM

For longitudinal adjustment the head unit is traveled directly on the bed, while for vertical adjustment the head proper is traveled upon the head column. These adjustments are accurately controlled through precision screws and observation dials. Powerful binders are provided for rigidly clamping the movable members after the required adjustments have been made. The spindle is liberally proportioned so as to obtain the necessary stability. Its bearing surfaces are throughout cylindrical. Bronze bearings are used, of a type that has proved satisfactory for this class of machine.

The greatest distance from the center of the table to the end of the spindle is $8\frac{1}{4}$ in.; the least is 3 in. The greatest distance from the center of the spindle to the

table top is $8\frac{7}{8}$ in.; the least is $1\frac{7}{8}$ in. From head spindle to foot-stock spindle the greatest distance is 17 in.

The spindle drive is by means of a single, constant-speed pulley, through gearing. Variations of spindle speeds are obtained by means of change gears. In order to eliminate the objectionable counter-shaft problem, a loose pulley, clearly shown in the rear view of the machine, enters into the construction of the spindle drive. This permits the machine to be belted direct to the line shaft. A belt shifter is provided, operated by a lever from the front of the machine.

An outboard support for the arbor also enters into the construction of the machine. The end of the spindle of the support is furnished with a hardened and ground bushing for the reception of the arbor end. Longitudinal adjustment is obtained by traveling the support directly on the bed. The vertical adjustment is accurately controlled through a precision screw and observation dial. Powerful binders are provided for clamping the movable members after adjustments have been made.

The proper lubrication of the cutter is well taken care of by a pump that delivers an abundance of lubricant. The pump is gear driven at a constant speed; thus the amount of lubricant delivered does not vary. For distributing the fluid onto the cutter, there is a nozzle that permits the width of the stream to be varied to suit the work in hand. A large pan section surrounds the lower portion of the bed for collecting the lubricant and chips. This pan, as well as the fluid tank, is cast integral with the bed proper. The tank is located in an accessible position where it can be easily cleaned. The fluid is strained and passed through settling chambers in the tank before being returned through the pump. In this way it is freed from foreign matter that is so destructive to pumps.

The operator is protected, as there are no exposed gears or dangerous members that may cause him injury. In this connection it may be well to emphasize that inclosing the gear units through which the spindle and feed changes are obtained prevents their manipulation by the operator. The intention is that the supervisor shall determine the correct speeds and feeds, after which they should remain undisturbed by the operator. Once the speeds and feeds are correctly determined, the machine has, barring accidents, a definite output per unit of time.

The miller weighs 3,750 lb. and occupies a floor space 54 in. square.

Future Machine-Tool Exports

By Carl Gebuhr

What influence will the European War have in the more distant future upon the exportation of American machine tools? This question is being asked by many. It seems to be the general opinion that Europe, after the war, will be in need of many things, and that the United States of America, being the only country to supply them, will continue to experience the present prosperity for some time after peace has been declared. This will undoubtedly prove to be true.

Immense values have been destroyed. They will have to be reconstructed. Whole armies will have to be reequipped, giving work to the arsenals and allied industries for probably many years to come. All railroads have suffered a great deal, and many machine tools will be required to rebuild the ships lost. Almost all the lathes in Europe and other tools that can be used for making war material have been running for the last two years on shell work, probably resulting in the ruin of many of them. As a matter of fact, whole countries will have to be reëquipped; and while all this demand naturally will influence the exportation of American machine tools until such time as Europe has somewhat regained its breath, what will be the outlook for the more distant future?

To understand thoroughly my reasons for not seeing any too bright a future ahead for the exporter of American tools, it will be necessary to recall the underlying force that has always kept this country ahead of all other nations in the construction of machine tools, particularly labor-saving machinery and devices. It was the law of necessity. Years back, the scarcity of labor forced upon this country its predominance in the construction of machine tools, while in succeeding years the ever-increasing wages and cost of production have also been a great factor in the further development of the labor-saving devices.

No such impetus ever existed for overcrowded Europe, with plentiful cheap labor. The great change that the present war probably will bring about and the great danger for the future of the American exporter of machine tools may be that after things have been readjusted the old world will find itself in the same position as this country in being forced by law of necessity into America's essential field. Undoubtedly, one of the reasons that has always allowed this country to find a market for its high-priced machine tools in Europe was the fact that it was practically without competition. Will it be the same after the war?

Three reasons may be advanced for predicting a change in Europe's machine industry—the loss in human labor suffered by all belligerent countries, the strong competition that will set in right after peace has been declared and the tremendous national debts accumulated.

While it is possible that the loss of labor will be felt to some extent in the machine-tool industries of the belligerent countries, it will hardly be as great as is commonly accepted. Of the three reasons given, it will probably turn out to be the one of least importance. Aside from the fact that the losses of human lives shown in the daily newspapers are greatly exaggerated, it should not be forgotten that all countries now at war of necessity had to keep their mechanics at home, so as not to cripple their factories. This is particularly true of the central powers, which are cut off from the rest of the world and have to produce their own war material.

It seems to be only reasonable to assume that all men not easily replaced and necessary for the smooth running of the industrial machine were not drawn, and only those whose places can be taken by unskilled labor had to join the colors. Apparently where most people seem to make a mistake is that, from the general losses suffered by all belligerent nations, they conclude that the machinery industry must have suffered proportionately. If, for instance, the central powers had drawn their men without regard to the efficient working of their factories, could they have supplied all by themselves the immense amount of war material required by the present struggle? Would it not have meant a death blow to their chances if they had crippled their means of keeping up the struggle by reducing the efficiency of their factories?

As the present war is showing, an efficient machinery industry constitutes part of the national defense, and to cripple it, particularly at the time the fight is on, would mean the battle lost. The truth of this statement would seem to be borne out by the fact that several of the allied countries were forced to create special munition ministries to organize the production of war material. All this would seem to allow the conclusion that of all industries in the belligerent countries (except Belgium) the machine industry has suffered the least, since it forms the backbone of the national defense and to break or even cripple it would have disastrous effects; hence, the aërial raids.

The far greater influence upon the future shaping of the exportation of American machine tools will be the extreme competition in the markets of the world, which may be expected after the war, and the tremendous national debts accumulated by all European nations. Those two reasons may force upon Europe that law of necessity which brought to this country its predominance in the construction of labor-saving machinery and devices. Competition will force all countries more than ever before to bring up their industries to the highest point of efficiency, which in view of the higher production costs that may be expected on account of the tremendous national debts can only be accomplished by using more labor-saving machinery. While for some time to come Europe may be forced to buy such machines here, it nevertheless would seem unreasonable to expect the other side to continue buying in this country at considerable prices what they may produce themselves at a much lower figure. It will not be very long before Europe will start in to build up its own labor-saving machinery industry, because the ever increasing demand for such devices will force upon the European machine-tool manufacturer that same duty which made the American manufacturer predominant in the construction of machine tools.

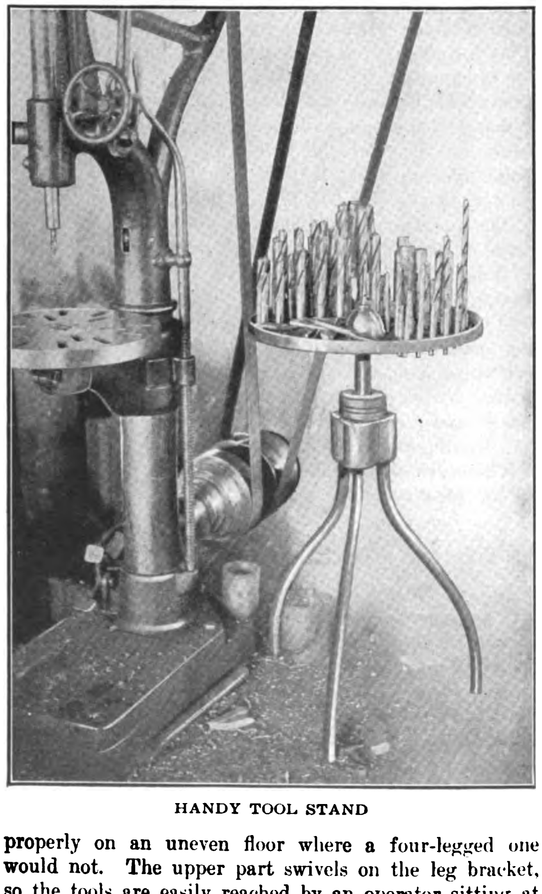
Of course, this does not hold true for all European countries. It will be many years before Russia, for instance, can supply her needs in machine tools, much less enter the markets of the world as a serious competitor. For a few years to come Russia will still represent a good field for the American machine-tool exporter; but as soon as the other European nations become able to enter the competition, it will not be surprising to see this country driven out of the field by a competition that can sell a product of the same quality and capacity at a price that impoverished Russia is in a better position to pay. After this war it will be the duty of all European governments to give the greatest possible aid to their machine industry, since this industry is a part of the national defense. While all this makes the outlook for the American manufacturer rather bright for the immediate future, there may be just so much greater a loss to him later. Apparently the present war has been of great benefit to this country's machine-tool industry, and one may claim that it will continue to be so. However, a closer investigation would show that the longer the war lasts the greater will be the industry loss in the future, because the more the national debts of Europe accumulate the greater will finally be the impetus for the developing of labor-saving machine industry on the other side.

While all appearances tend to point toward a booming business right after the war, there are nevertheless signs that indicate otherwise. It should not be forgotten that Europe within the last two years has bought more machinery than it would have bought in normal times within six years. Although it is claimed that through incessant use almost all those machine tools have been ruined, yet it remains to be seen how far impoverished Europe will go in replacing them with new machines. All governments will lend their aid to the quick reëstablishment of their machine industries, and it may very well be possible that Europe will help itself with what it has and wait for its own factories to resume deliveries rather than continue paying money to this country.

In any case no matter what the immediate future will bring, it seems that the hurtful effect the European War will have on the exportation of American machine tools will be to force upon Europe the necessity of building up its own labor-saving machine industry. While this does not mean that this country will entirely lose Europe as a customer of machine tools, it nevertheless may accelerate what in the normal course it would have taken many a year to accomplish—the final loss of Europe as the main field of export.

Handy Tool Stand

The tool stand shown is used in the shop of the Western Foundry and Machine Works, Topeka, Kan., principally for holding the larger sizes of drills. It is very simple and easily made, and the three legs make it rest



HANDY TOOL STAND

properly on an uneven floor where a four-legged one would not. The upper part swivels on the leg bracket, so the tools are easily reached by an operator sitting at a machine.

Making 3-In. Russian Shrapnel in a Pump Shop

By Ethan Viall

SYNOPSIS—The machines and tools described in this article were nearly all made in the works where they are used, expressly for manufacturing shells. They show what a first-class American plant can do in fitting up for work, even if it is somewhat out of the regular line. The turret lathes were made in the shop—from patterns to the complete machines. With the advantage of not having to do the best possible with a lot of made-over machines, there is little lost motion anywhere.

A large majority of the shops doing shell work of whatever character have either bought machines or have fitted up those already on hand. At the time the Hill Pump Co., Anderson, Ind., decided to do shell work, it was found that machines suitable for its purposes were of both very high price and uncertain delivery. On this account and because it has a large, well-fitted shop and

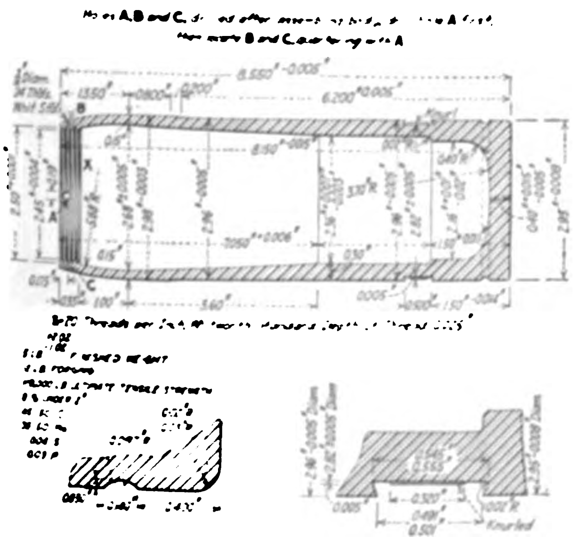


FIG. 1. DETAILS OF 3-IN. SHELL

foundry of its own, this company decided to make for itself whatever equipment was necessary. In consequence two sizes of turret lathes were designed and built, together with all the needed tools and special attachments.

For this reason there is nothing spectacular about the shell work, but it represents good American shop practice. The turret lathes were built in sufficient numbers to supply not only the Hill company's own needs, but those of several others doing the same class of work. These lathes have already been described in detail in these columns, and in this article the shell work done on them, as well as on others specially fitted, will be presented.

At the time the material for this article was obtained a majority of the machines were at work on 3-in. Russian shrapnel shells. The forgings, in the form of cylinders with one closed end, are received from a steel mill. These forgings, as delivered, weigh about 7 lb. 13½ oz. each, and the work done in this shop reduces them to a minimum of 5 lb. 7 oz. or a maximum of 5 lb. 10 oz. The shell is shown in section, Fig. 1, together with the various

measurements and specifications. Some of the lots of forgings have to be pickled before machining, but often this is not needed.

Disregarding for the time being several inspections, the shop operations proceed in the following order:

1. Pickling (if needed)
2. Cutting off in lathe
3. Machining for centering in drilling machine
4. Centering in drilling machine
5. Scoring for driver in air press
6. Rough-turning
7. Facing base
8. Rough taper boring
9. Roughing out diaphragm chamber and seat
10. Rough - drilling powder pocket
11. Heat-treated
12. Finish taper bored
13. Second roughing of diaphragm chamber and the seat
14. Roughing out powder pocket
15. Finishing powder pocket, diaphragm chamber and seat
16. Finish facing base
17. Nosing
18. Rough-boring and facing open end
19. Finish-boring end
20. Tapping
21. Profiling
22. Grooving for rotating band and crimping seat
23. Dovetailing
24. Knurling
25. Grinding two diameters
26. Grinding end of base
27. Inspection all over
28. Banding

See page 943 for graphical representation of operations.

Several number-stamping operations and the screwing in of a special centering plug after the tapping operation have been purposely omitted from the list. A too detailed account of the various operations will not be given, as many of them have been fully covered previously.

The shell-machining shop is well lighted and well arranged for its single purpose. A good concrete floor makes the trucking an easy matter. The forgings are stacked in double pyramidal piles on wooden truck platforms, Fig. 2. Lift trucks of the type shown are used to move the work from place to place. Both the forgings and a large part of the machined work are thus moved.

rod is made to slide in the holding bracket *B*, and when in gaging position may be locked by a pin that fits into an offset slot at *C*. A trimmed shell is shown at *D*. As

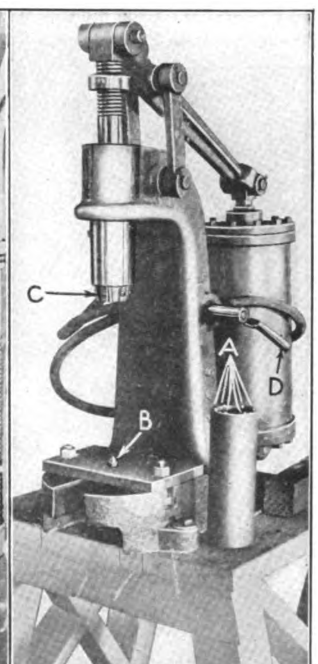

FIG. 6. SCORING FOR DRIVER

Machine Used—Hannifin air press, 100 lb. pressure.
Fixtures Used—Baseplate with center, six-blade scoring tool.
Gages—None.
Production—10 to 15 per min.
Lubricant—None.
Reference—Fig. 6-A.

The first machining operation is to trim or cut off the forging to a length of $8\frac{3}{16}$ in., measuring from the inside. This is done in a Hill motor-driven lathe, Fig. 3. The forging is chucked in a universal, three-jawed chuck. The right setting is obtained by a setting rod *A*, the end of which butts against the inside end of the work. This soon as the work is set and the chuck jaws are tightened, the gaging rod is pulled back out of the way.

After being cut off, the forging goes to the drilling-machine fixture, Fig. 4, and the plug on the bottom, or "button," is machined off to a definite distance from the inside end. One of the forgings is shown at *A*. It is

slipped down over the expanding mandrel *B* until the inside end rests on the stop *C*. After the shell is on the mandrel, it is swung up under the bushing yoke and locked by the knurled-head pin *D*, which slides in the hole *E* and enters a corresponding bushed hole in the carrier. The expanding jaws of the mandrel consist of two sets, of three each, like those at *F*. They are moved in or out by a sliding taper pin in the center of the mandrel, which is operated by a cam movement and by the hand and foot levers *G* and *H*. The expanding-mandrel jaws are held in contact with the taper center pin by band springs *I*, which are snapped into recesses milled in the jaw ends.

The drill J works through a steel bushing in the top of the yoke and is ground almost straight on the cutting end. Just enough lip angle is ground on it to leave a slightly hollowed spot for the center drill to operate in.

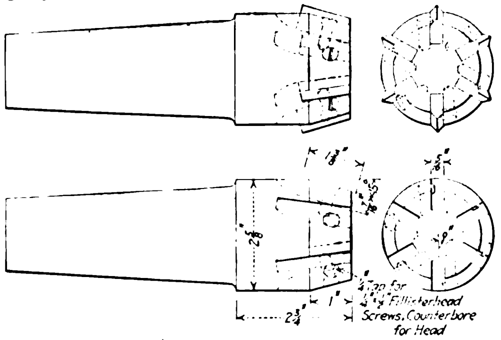

FIG. 8. DETAILS OF SIX-POINT WORK DRIVER

The centering is done with a combination center drill and countersink, using the fixture seen in Fig. 5. This is very similar to the one just shown, except that there is no hand or foot lever used. The action of swinging

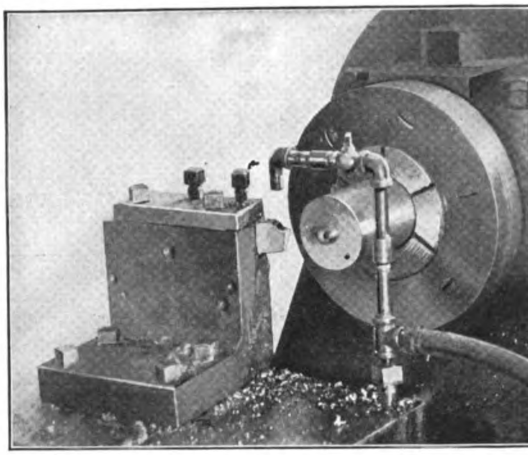

FIG. 9. FACING BASE

Machine Used—Hill No. 3 motor-driven lathe.
Fixtures Used—Regular expanding chuck and tool block.
Gages—One chuck and two carriage stops, go and not go gage for length.
Production—31 per hr.
Lubricant—Soapwater.
Reference—Fig. 9-A.

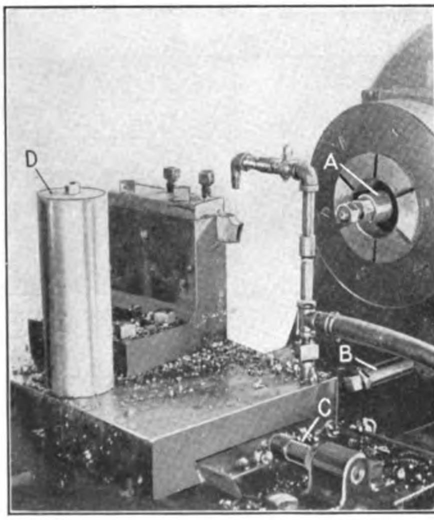

FIG. 10. BASE-FACING LATHE, SHOWING STOP

Machine Used—Hill No. 3 motor-driven lathe.
Fixtures Used—Same as shown in Fig. 9.
Gages—One chuck and two carriage stops, go and not go gage for length.
Production—31 per hr.
Lubricant—Soapwater.

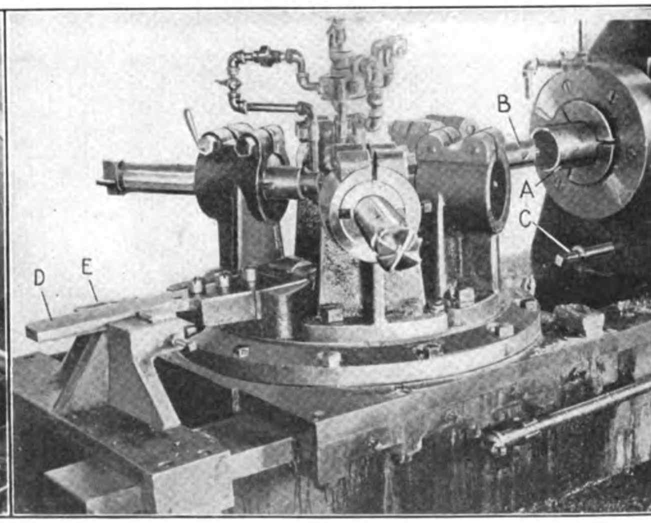

FIG. 11. ROUGH TAPER BORING

Machine Used—Hill No. 3 turret lathe.
Fixtures Used—Profiling attachment for turret, single-point boring tool.
Gages—One chuck and one carriage stop, plug and taper-plug.
Production—21 per hr.
Lubricant—Soapwater.
Reference—Fig. 11-A.

the carrier up under the yoke slides the lower end of the taper pin over a cam underneath and causes the jaws to expand and grip the shell. The carrier is locked in place by a sliding pin A exactly as in the other fixture. As the carrier is pulled toward the operator after the work is drilled, the action automatically releases the jaws, and the shell may be easily lifted off the mandrel.

For the roughing outside work the shell is held between a tail center and a six-point driver in the lathe spindle. To make it easy for the lathe operators to set the shells, the driving points are scored into the open end of the shells in the air press, Fig. 6. One of the shells is shown with the scored points indicated at A. In doing the work the shell is set with its center hole over the locating center B. The scoring tool C is then brought down by operating the valve lever D.

Next comes a lathe operation, which consists in roughing off the outside. The shell is held, as in Fig. 7, between the tail center A and the six-point driver B, shown in detail in Fig. 8. Except for some minor features it is the same as the scoring tool of the previous operation. About $\frac{9}{32}$ in. of metal is removed from the diameter of the forging in this roughing operation, using a No. 2 stellite tool in an Armstrong holder.

For facing the base the shell is chucked as in Fig. 9. In order quickly to set the shells a uniform distance into

the chuck jaws, a special stop A, Fig. 10, is used. Another stop B is provided to butt the carriage against, and the stop C gives the correct distance for feeding in the cross-slide. A shell roughed all over the outside may be seen at D.

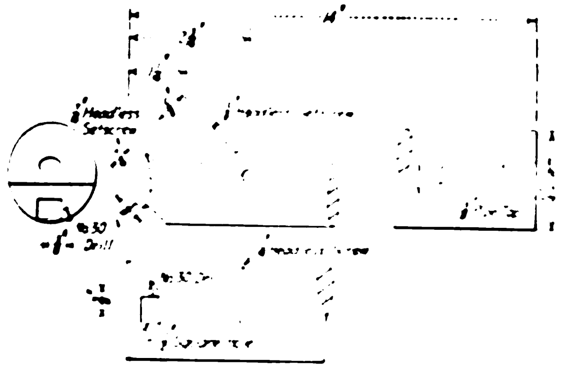

FIG. 12. DETAILS OF TAPER FORMING TOOL

The first machine operation on the inside is to rough taper bore, Fig. 11. The bore is not a straight taper, but from the outside end the shell is bored straight for 1.631 in., then taper for 3.60 in. and straight again for 1.850 in. The shell is held in the lathe chuck, as at A. The boring is done with a single-point tool B, which is shown in detail in Fig. 12. A stop C regulates the carriage travel. The taper boring is really a profile operation, controlled by a master D on the back of the turret.

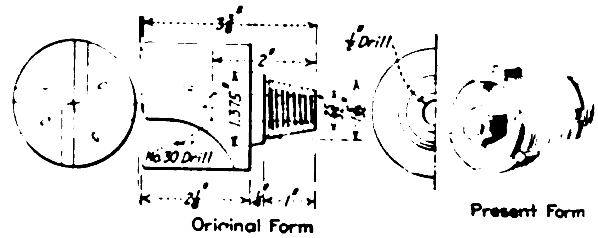

FIG. 15. DETAILS OF ROUGHING TOOL FOR DIAPHRAGM CHAMBER AND SEAT

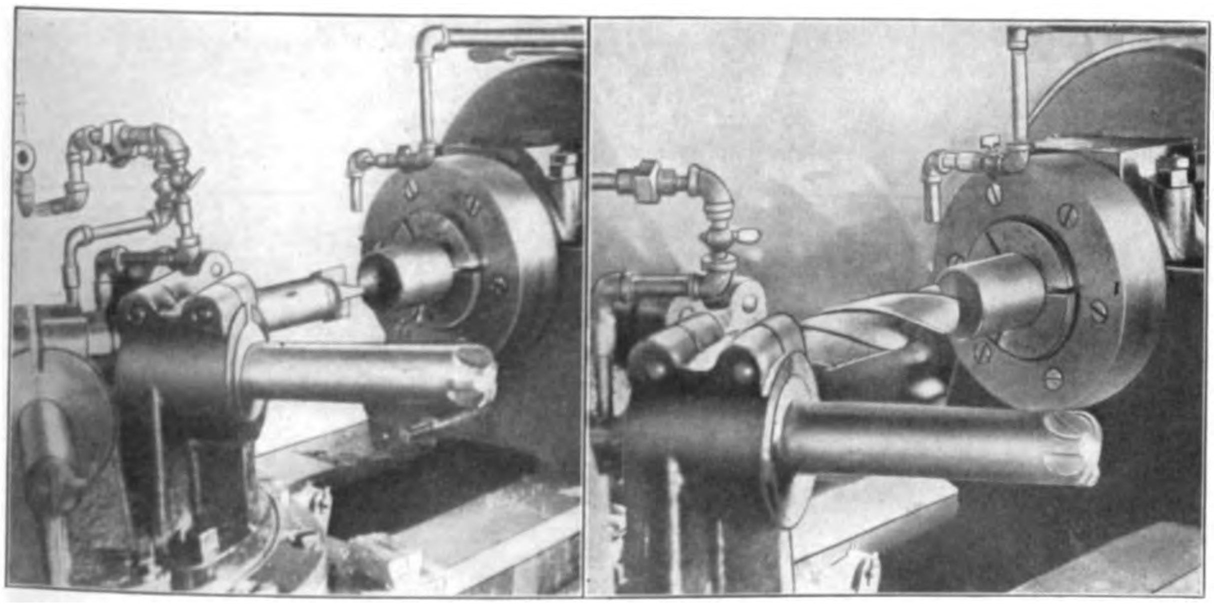
This master slides between guides in the bracket E, which is bolted to the lathe bed. When other operations are being performed, the master is raised up out of the guides and is carried by the turret, to which it is hinged. Details of this attachment, and the way it is placed on the turret, are given in Fig. 13.

In some cases the taper boring and the next two operations are performed on the same machine; in others the last



FIGS. 14 AND 16. ROUGHING OUT DIAPHRAGM CHAMBER AND SEAT AND ROUGH-DRILLING POWDER POCKET (TWO OPERATIONS)

Machine Used—Bell No. 3 turret lathe. Fixtures Used—One special boring tool and one round cornered drill. Gages—One chuck and one carriage stop, flat steel, double end, go and not go. Production—15 per hr. Lubricant—Soapwater. References—Figs. 14-A and 16-A.

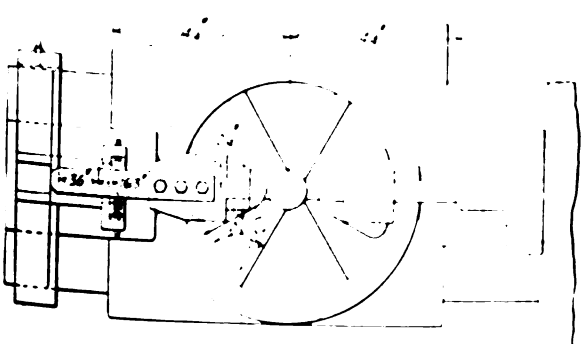


FIG. 13. DETAILS OF TAPER-TURNING ATTACHMENT

two are done on another machine, which accounts for some apparent discrepancies in the set-ups shown. This is also true of some of the finishing operations. However, for convenience we will consider the taper boring as a separate operation and the two operations of roughing out the diaphragm chamber and seat and rough drilling the powder pocket as done on another machine.

Following the taper boring, the diaphragm chamber and seat are roughed out with the tool seen in Fig. 14 and again, in detail, in Fig. 15. When the photograph was taken, a tool similar to an endmill was used; but since then a three-cutter head has been substituted and found to give better results. The latter is also shown.

The rough-drilling of the powder pocket is accomplished with a round-cornered drill, Fig. 16, which is $2\frac{1}{8}$ in. in diameter and is run in to a depth of $8\frac{3}{16}$ in.

The shells have now been roughed outside and inside and are sent to be heat-treated. The heat-treating room is conveniently arranged, as can be seen from Fig. 17. The heating furnace is shown more in detail in Fig. 18. Above, the preheater is full of shells. The shells are preheated to 800 deg. and are then placed in the heating bath in front and heated to 1,500 deg.; 50 deg. is allowed for removal from the bath to the quenching tank. Houghton's quenching oil at 1,450 deg. is used in the tank.

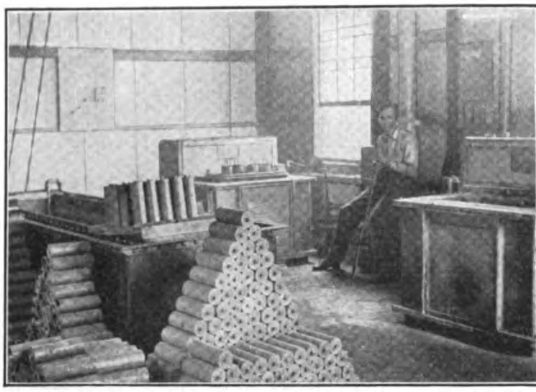

FIG. 17. THE HEAT-TREATING ROOM AND APPARATUS

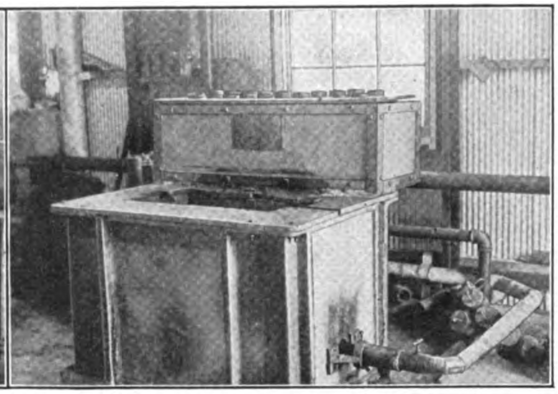

FIG. 18. THE PREHEATING AND HEATING FURNACE

Furnace Used—Tate-Jones.
Special Apparatus—Handling tongs and handled weights, pyrometers and alarm bells for timing.
Production—1 per min., heated 8 min. each.

The drawing is performed in the heater in Fig. 19. The shells are placed in the lead bath and held down by the handled weights, shown. They are drawn to 1,050 or 1,100 deg. and allowed to cool in the air. The degrees of heating and drawing vary somewhat with the different lots of steel, and each lot has to be tested separately and treated accordingly. A chart on the wall shows the operator what treatment to give certain numbered lots.

From the heat-treating the shells are trucked back to the machine shop, where the first machining operations are done on the inside of the shells. The inside finishing work closely approximates the roughing work, and very similar tools are used.

The first operation is finish taper boring, the machine and tools being the same as previously shown. Oil, however, now serves as a lubricant, and the production is 15 per hr.

The diaphragm chamber and seat are semifinished with a tool similar to the roughing tool. The powder pocket is rough-tooled out, as may be seen in Fig. 20 and

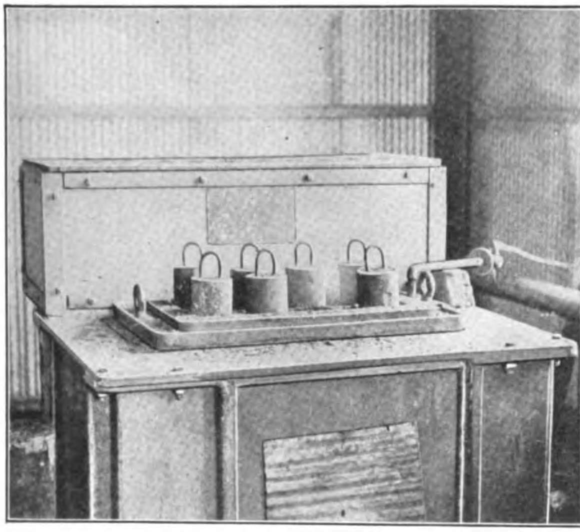

FIG. 19. DRAWING FURNACE AND LEAD BATH APPLIED PRIOR TO FINISHING CUTS

Furnace Used—Tate-Jones.
Special Apparatus—Handling tongs and handled weights, pyrometers and alarm bells for timing.
Production—1 every 2 min., heated 16 min. each.
Note—Drawing temperatures vary with different lots of steel. The variations are charted.

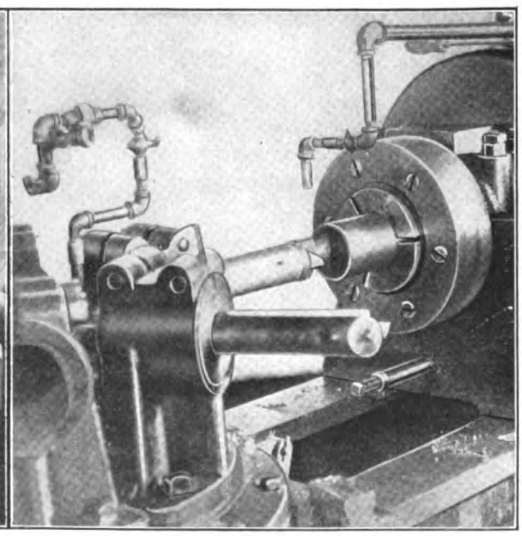

FIG. 20. FINISHING DIAPHRAGM CHAMBER AND SEAT AND POWDER POCKET

Machine Used—Hill No. 3 turret lathe.
Fixtures Used—Special head cutters.
Gages—Plug and flat double end, go and not go.
Production (three operations)—12 per hr.
Lubricant—Oil.
Reference—Fig. 20-A.

in detail in Fig. 21. These two tools are followed by a combination finishing tool, Fig. 22, illustrated in detail in Fig. 23. This tool finishes the diaphragm chamber,

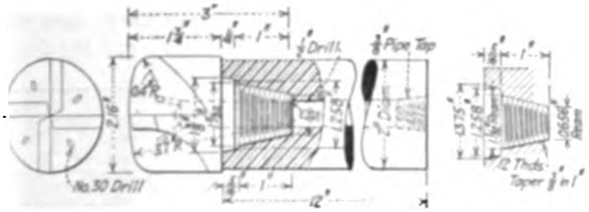

FIG. 21 DETAILS OF POWDER-POCKET ROUGHING TOOL

the seat and the powder pocket all at once. The base is finish-faced, as in the roughing operation, the production being 10 per hr. The heat number is then restamped on the base, and the shell is ready for nosing.

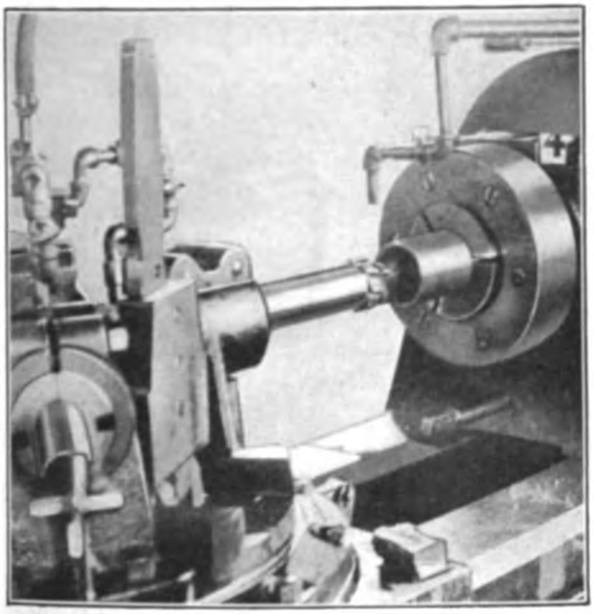

FIG. 22 FINISHING DIAPHRAGM CHAMBER AND SEAT AND POWDER POCKET

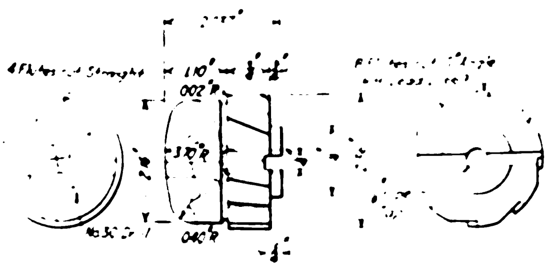

FIG. 23 DETAILS OF TOOL FOR FINISHING DIAPHRAGM CHAMBER AND SEAT AND POWDER POCKET

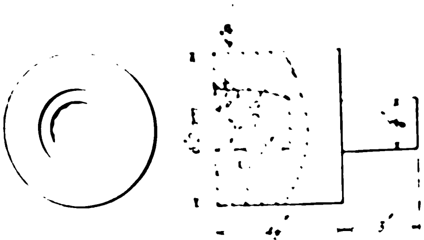

FIG. 25 DETAILS OF NOSING DIE

The nosing operation consists of closing in the open end of the shell, Fig. 24. This is done cold, using a little lard oil to lubricate the closing die. The end is closed in to about $2^{21}/_{64}$ in., the main body of the shell being 3.01 in. in diameter. The closing-in extends back about

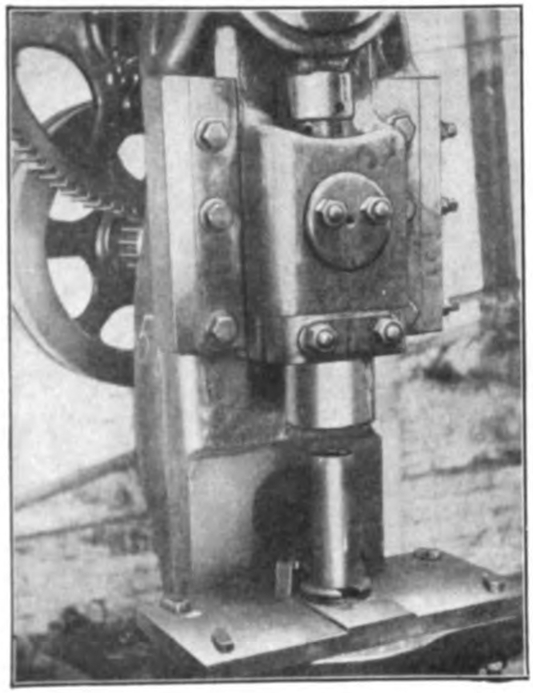

FIG. 24 NOSING

Machine Used—Punch press.
Fixtures Used—Closing die and slotted bed block.
Gages—Two setting stops at back of holder.
Production—300 per hr.
Lubricant—Lard oil.
Reference—Fig. 24-A.

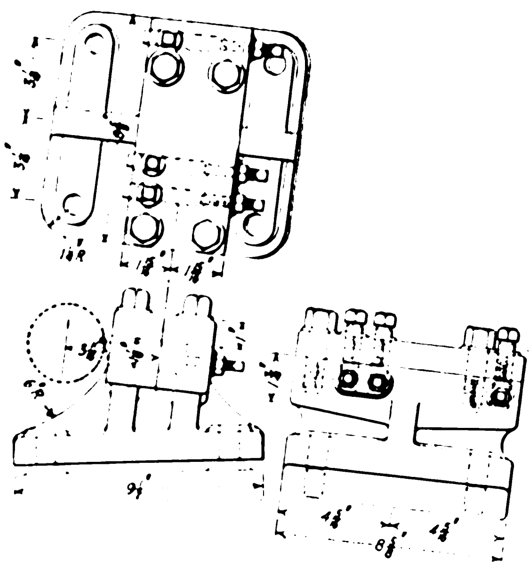

FIG. 27 DETAILS OF PROFILING TOOL BLOCK

$1\frac{3}{16}$ in., the measurements being outside and only approximate. Details of the nosing die are shown in Fig. 25.

The next three operations are completed on the same lathe. The shell is chucked as in Fig. 26, and the nose is rough-bored and faced. It is then finish-bored and tapped. For this work No. 1 lard oil is employed, with about 5 per cent. kerosene in it to make it run right.

A centering plug with a crosshandle for driving purposes is screwed into the shell, giving it two center holes to locate it between centers. It is then placed in a lathe fitted with a heavy tool block carrying three cutting tools that profile the shell as they are fed along parallel to it, turning the shell to three different diameters in different sections of its length. Details of the tool block used are given in Fig. 27. The production is 27 per hr., with soapwater as a lubricant.

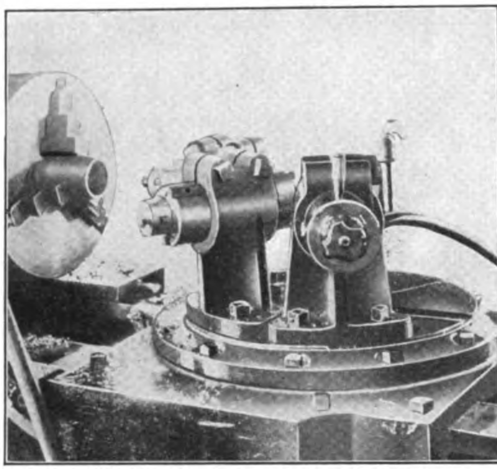

FIG. 26. BORING AND TAPPING NOSE
Machine Used—Hill No. 3 turret lathe.
Fixtures Used—Two single-point boring tools and Murchey collapsing tap.
Gages—Stop back of chuck, carrier stop, plug thread gage.
Production (three operations)—25 per hr.
Lubricant—No. 1 lard oil with 5 per cent. kerosene.
Reference—Fig. 26-A.

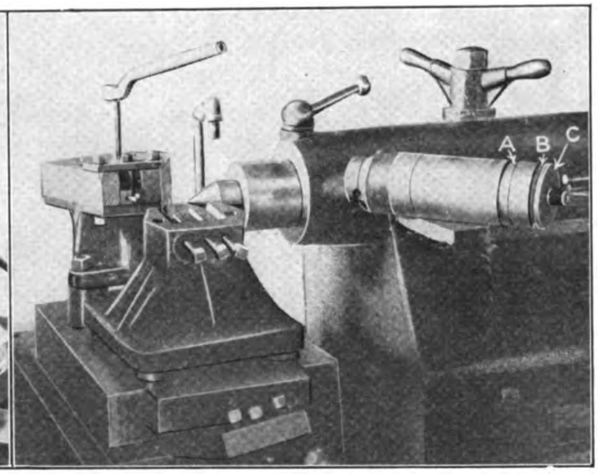

FIG. 28. GROOVING AND DOVETAILING
Machine Used—Lathe.
Fixtures Used—Special three-cutter tool block, special dovetail cutting device.
Gages—Three carriage stops, groove snap gage, dovetail gage.
Production—31 per hr.
Lubricant—Soapwater.
Reference—Fig. 28-A.

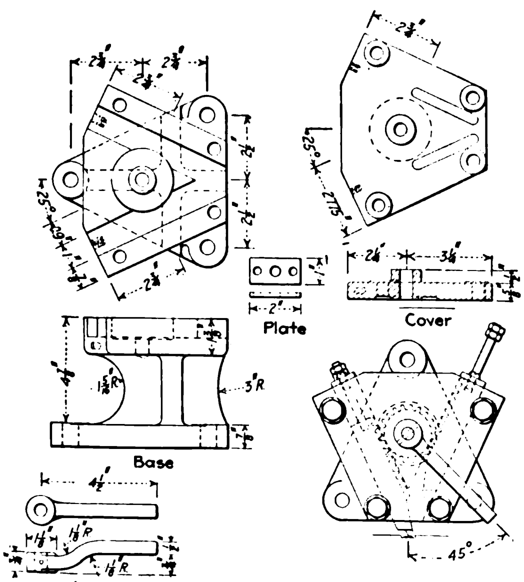

FIG. 29. DETAILS OF THE DOVETAILING TOOL

The grooving and dovetailing for the rotating band are done in the machine in Fig. 28. Besides the band groove, a groove is also cut for crimping in the edges of the cup that holds the propelling charge. Besides these two grooves, the base edge is chamfered. The two grooves and the chamfer are cut with three tools at once, set in the block on the front of the carriage. The clamping top is removed from this block in order to show the position of the three cutters. The grooves and the chamfer are indicated on the shell at *A*, *B* and *C*. The dovetailing is cut with the special crosstool device on the rear of the carriage. This device is shown in detail in Fig. 29. The operation of the dovetailing cutters leaves a slight ridge in the center of the groove for the knurling operation.

From the grooving lathe the shells go to the lathe illustrated in Fig. 30, where the bottom of the rotating-

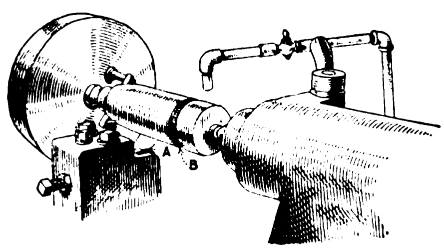

FIG. 30. KNURLING
Machine Used—Lathe.
Fixtures Used—Tool block to hold knurl.
Gages—Snap gage.
Production—60 per hr.
Lubricant—Soapwater.
Reference—Fig. 30-A.

band groove is knurled. The knurl is seen at *A* and the work at *B*.

The shells are ground on two diameters in front of the band groove, Fig. 31. Next, they go to the grinder, Fig. 32, where the buttons are ground off the bases. A shell with the center button still in place is shown at *A* and a ground one at *B*. The grinding fixture is simple and consists of two V-blocks and an adjustable end stop. A

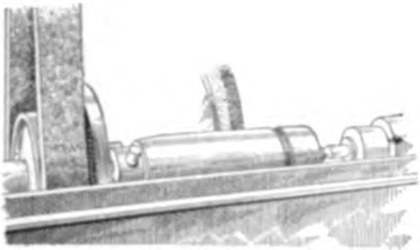

FIG. 31. GRINDING -TWO DIAMETERS

Machine Used Landis grinder
Fixtures Used—None.
Gages—Snap go and not go.
Production—10 per hr.
Reference—Fig. 31-A.

screw clamp holds the shell in place as the operator swings the work back and forth past the wheel.

After this last grinding the shells are thoroughly inspected all over. Careful check is kept in the shop also by inspectors as the shells pass from one machine to another. In addition to this the machine operators have gages to use where needed. Some of the rough and shop gages are shown in Fig. 33 and some of the finish gages in Fig. 34. A few of these are given in detail in Fig. 36, but on account of the large number of similar gages that have already been illustrated in our columns it has not been thought advisable to attempt to show more. The gages illustrated represent the types provided in this shop.

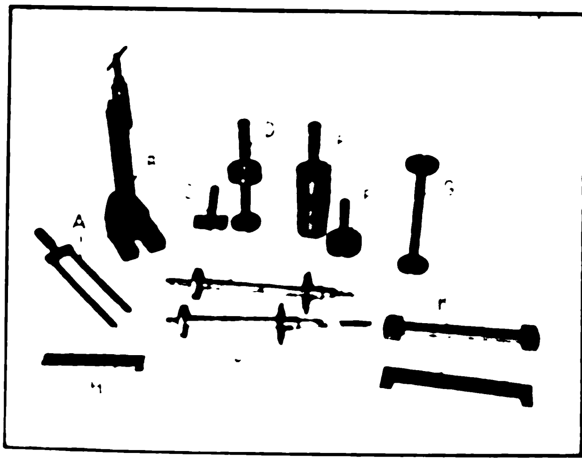

FIG. 33. ROUGH OR SHOP GAGES

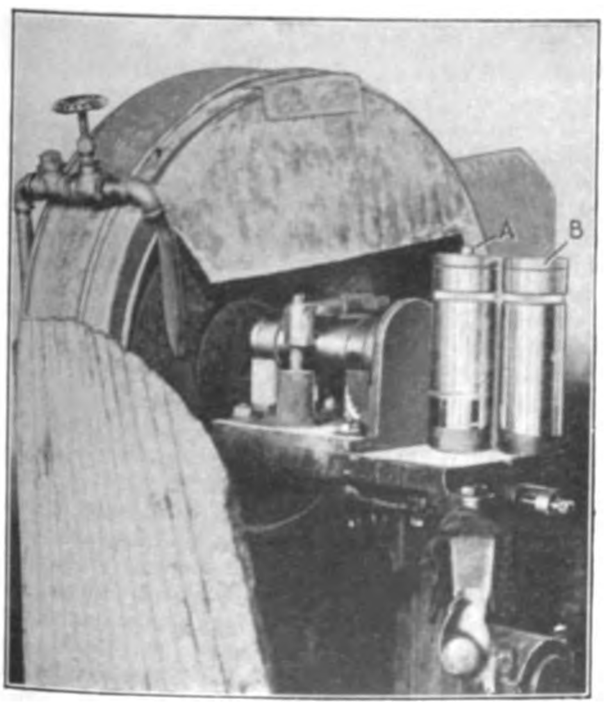

FIG. 32. GRINDING OFF CENTER BUTTONS

Machine Used—Gardner disk grinder.
Fixture Used—Special holder on swing carrier.
Gages Used—Overall.
Reference—Fig. 32-A.

The copper rotating bands are received all ready to slip down over the shell. This work is done by hand, or sometimes the bands need to be lightly tapped down. The shell with a band in place is set into a West banding machine at the rate of 95 per hr. The holder is just high enough to guide the copper band into the groove as the jaws close in around it. An expanding plug or mandrel is placed inside the shell to prevent any possibility of

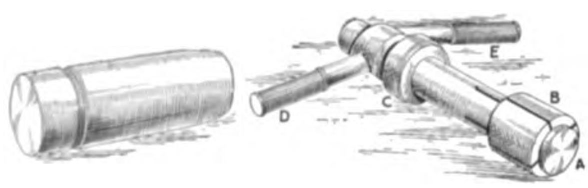

FIG. 35. THE EXPANDING MANDREL

distortion or crushing. This mandrel is shown in detail in Fig. 35. Here the taper center *A* is seen projecting slightly from the end of the expanding sleeve *B*. The mandrel is dropped into the shell until the shoulder *C* rests on the nose. The handle *D* is then held with one hand and the handle *E* turned with the other. This action draws in the taper center expanding the sleeve and supports the inside of the shell just under the band groove, effectually preventing the groove from bulging inward.

This is the last operation in this shop, as the rest of the work is done elsewhere. After the final inspection the shells are shipped out.

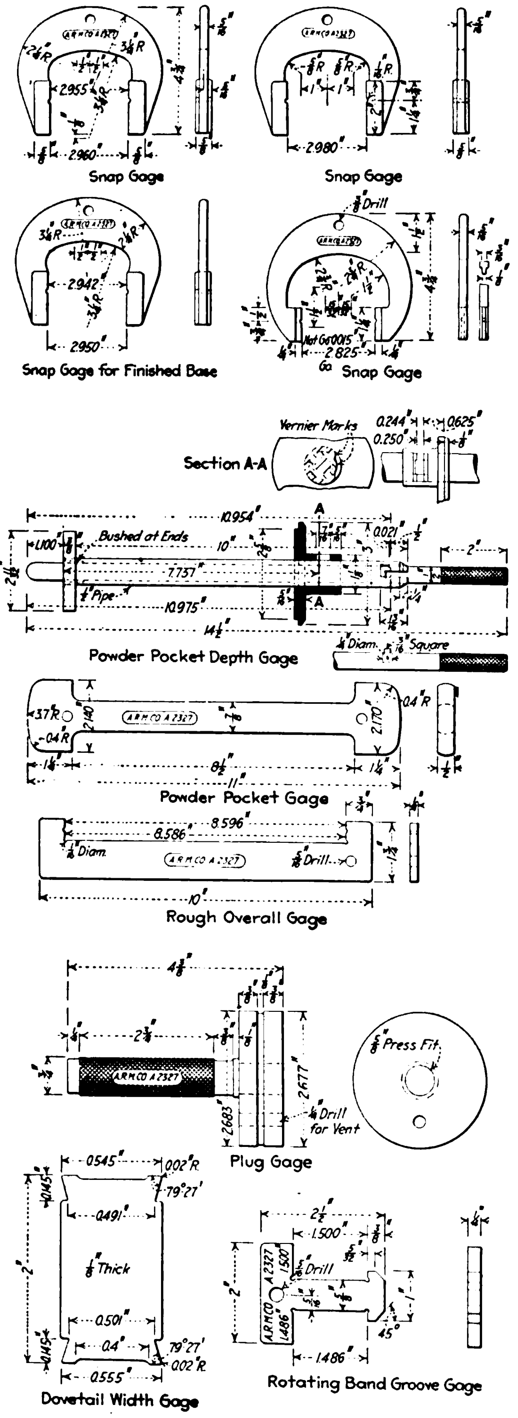

FIG. 36. DETAILS OF A FEW OF THE GAGES, SHOWING TYPES USED

In the foregoing article it was intended to cover the general methods only, inasmuch as the details of the manufacture of the 3-in. Russian shrapnel have been covered in previous articles.

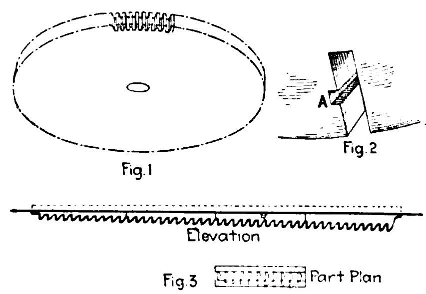
Broaching Special Slots in Turbine Drums

By H. B. McDermid

In manufacturing one type of Parsons turbines the problem of cutting a large number of special slots in connection with the blading work was put up to the boss tool maker for solution. The stock was brass or bronze in the form of disks about 1/4 in. thick, averaging perhaps 30 in. in diameter. Each disk contained a large number of slots; and as there were quantities of the disks to be machined, it was important to devise some method that would permit rapid production.

Fig. 1 shows the design of the piece, and Fig. 2 is an enlarged view of the special slots to be cut. The disk was mounted on a heavy disk or jig of a diameter enough smaller so that the supporting jig or fixture just cleared the bottoms of the slots of the finished piece.

The whole contrivance was then mounted upon the crossrail of a planer, and a spacing device was connected to the regular planer feed system so that with each stroke



BROACHING SPECIAL SLOTS IN TURBINE DRUMS WITH MULTIPLE-TOOTH BROACH

of the planer platen the work was revolved through an angle equal to the spacing of the slots and rigidly held in place during the cutting stroke.

The multiple-toothed broach, Fig. 3, was clamped in place on the planer bed. This broach was made in sections, the first tooth being the shortest and the line of the points of the others forming an acute angle with the planer platen, so that each tooth would remove a chip from the stock and the last one would finish the slot to the desired depth. The section *A* of the tool had side points parallel to the planer bed, for cutting the side notch *A* in the slot, Fig. 2. Its first tooth started the slot, and its last completed the work to finished size. Thus with every stroke of the planer a slot was completed to size, the tool withdrawn, the piece revolved by the feed mechanism through the proper angle, and another cycle of operations started.

The work, being mounted on a tool head, could quickly be adjusted both horizontally and vertically; and once set at the proper height with its vertical center line over the tool, the work could be completed very rapidly, the changing of blanks necessitating the only pause in the job.

It will be noticed that the small side slot complicated this tool problem somewhat, as for a plain slot several other methods might have been used. In this instance only one block was machined at a time, but with a more rigid fixture several might be machined.

Some Recent Developments in Tool-Steel Testing

By R. Poliakoff*

On page 419 the beginning of Mr. Herbert's article, "Some Recent Developments in Tool-Steel Testing," is published. In this article the author refers (p. 421) to my experiments with finishing-operation cuts and reproduces two of my curves. About the work itself he says that it has been published in the Russian language only and expresses the hope that I may be "persuaded to make it available to readers in English." In connection with this I may mention that my "Experiments with Lathe Finishing Tools" was made also the subject of a paper presented to the Manchester Association of Engineers (England), and this paper has been published in the "Transactions" of the association. Following is an abstract:

Considerable attention has been given to the variation in durability with change in the cutting speed when taking roughing cuts with carbon-steel and high-speed steel tools, but very little experimental evidence has been published on the durability of these steels when taking extremely fine or finishing cuts. The paper read by E. G. Herbert before the Iron and Steel Institute in 1910 deals with fine cuts, but these were obtained in trials made in his special tool testing machine and not in a lathe. The experiments referred to in this paper were made in an ordinary lathe and under conditions identical to those prevailing in the workshop. The tests were made with the object of showing the relation between the length or surface machined and the cutting speed for a prescribed degree of tool wear.

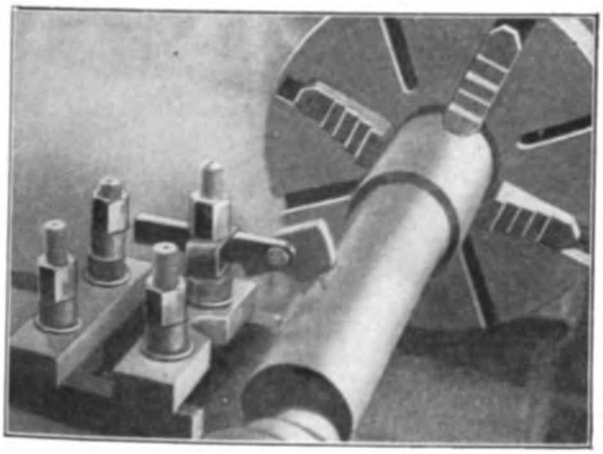


FIG. 1. INDICATOR IN POSITION FOR MEASURING WEAR

To carry out these tests a short piece of steel (part of a locomotive axle containing about 0.38 per cent. carbon) about 1½ in. in diameter was selected in order to give the necessary rigidity, and cutting was continued until the tool reached a predetermined bluntness. To measure the durability after the manner adopted for roughing tools—that is, to continue cutting until the edge of the tools breaks down—was found to be impractical and to judge from the appearance of the bar lacked definiteness. The bluntness was therefore observed as the trial progressed by means of an indicator fixed in the rest immediately behind the tool (see Fig. 1). The indicator was set to zero at the commencement of the cut and pressed against the bar so that as the tool became blunt and lost its cut the radius of the bar increased by a like amount and this was shown by the indicator. The indicator was graduated in two-thousandths of an inch, and the degree of tool bluntness decided upon for these tests was 0.003 in.—that is, about 25 per cent. of the depth of cut. The lathe, however, was not stopped when the indicator attained this figure, but allowed to cut until the gage indicated 0.002 in. As the exact degree of bluntness is difficult to measure when the tool is cutting, the indicator, on the tool being withdrawn, was brought back to the starting point and the bar carefully measured as the saddle was slowly traversed by hand.

The distance from the beginning of the cut to the spot where the indicator showed an increase of 0.003 in. was carefully measured. The indicator was then brought back to the starting point, the bar moved through 90 deg. and

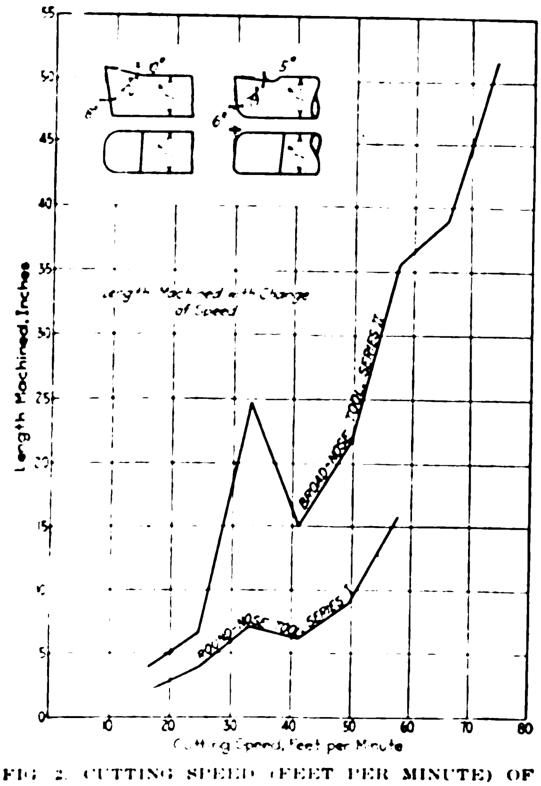

FIG. 2. CUTTING SPEED (FEET PER MINUTE) OF CARBON-STEEL TOOLS

Length machined with change in cutting speed

the foregoing operation repeated. Similarly the distance traversed for the indicator to show an increase of 0.003 in. was observed at 180 and 270 deg. to the first observation. There was very little difference between the four measurements, and the average of these was taken to represent the length machined by the tool ere it attained the prescribed bluntness. A lubricant of soap and water was used in all the tests.

After each test the tool was reground in a universal tool grinder and an oil stone was drawn lightly across the cutting edge to slightly round off the feather edge and prevent crumbling at the commencement of the cut.

Tests with Carbon-Steel Tools—Series I and II were made when taking a cut $^1/_{150}$ in. deep by $^1/_{72}$ in. traverse. The former were carried out with a round-nosed tool having a cutting angle of 80 deg. and at speeds between

*Assistant professor of mechanical technology, Imperial Technical Institute, Moscow, Russia

16 and 57 ft. per min., while the latter series was made with a broad-nosed tool having a cutting angle of 85 deg. and at various speeds between 16 to 74 ft. per min.

The results of these trials are shown in Fig. 2 with the cutting speed as ordinate and the length machined as abscissa.

As the diameter of the bar (4.6 in.) was practically the same for both series of trials, the surface machined is

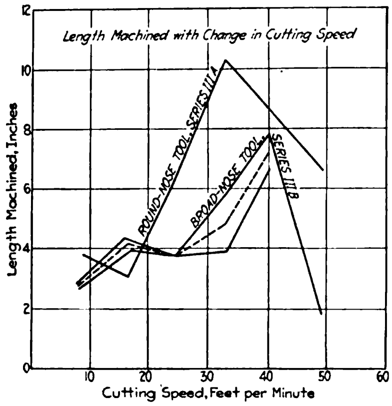

FIG. 3. CUTTING SPEED (FEET PER MINUTE) OF HIGH-SPEED STEEL TOOLS

Length machined with change in cutting speed

directly proportional to the length machined and both sets are comparable.

Tests with High-Speed Steel—Series IIIa and IIIb, also IVa and IVb, were made with tools having a cutting angle of 75 deg. on a bar (same as used in the carbon-steel trials) about 4.2 in. in diameter. The tools used in trials IIIa and IVa were of the broad-nosed type, while the tools used in trials IIIb and IVb were of the round-nosed type (for sketch of tools see Fig. 2). The results obtained

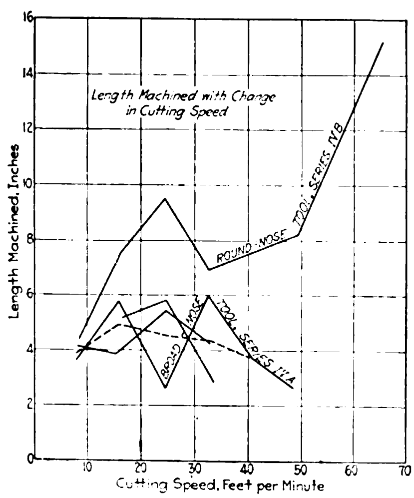

FIG. 4. CUTTING SPEED (FEET PER MINUTE) OF HIGH-SPEED STEEL TOOLS

Length machined with change in cutting speed

in the foregoing tests are shown in Figs. 3 and 4, where the cutting speed is plotted against the length machined. Lines connect the observations of the different sets, and the latter are marked with their series number. The dotted line represents the mean of the observations for the several sets with broad-nosed tools.

If the quality of the finish at different speeds as shown by photographs (not here reproduced) could be represented on a diagram, the latter would take a form very similar to that given for the relation between the cutting speed and surface machined. The number of trials, however, is insufficient to enable any definite conclusions being arrived at, but so far as they go they generally indicate:

1. That carbon-steel tools on the cuts taken are more durable and capable of machining a greater surface than high-speed steel tools (compare Figs. 2, 3 and 4).

2. That the surface machined (for a prescribed degree of bluntness), particularly in the case of high-speed steel tools, is not constant for all speeds, but varies irregularly with the speed (see Figs. 3 and 4).

3. That the quality of the finish improves as the cutting speed decreases. At high speeds the tool appears to pluck and tear the surface, and instead of the cuttings being sharp they are frayed at the edge. This conclusion is supported by an examination of the photographs of the surface of the bar, micro-photographs of the same and photographs of the chips themselves.

4. That the broad-nose carbon-steel tool gives consistently better results than the round-nose tool, whereas in the high-speed steel tests the reverse is the case; that is, the best results are obtained with the round-nosed tool. Below 36 ft. per min. the round-nose high-speed steel tool is generally better than the round-nose carbon-steel tool, but above that speed the latter tool gives the best performance. At all speeds the broad-nose carbon-steel tool machines a greater area of surface than any of the high-speed steel tools.

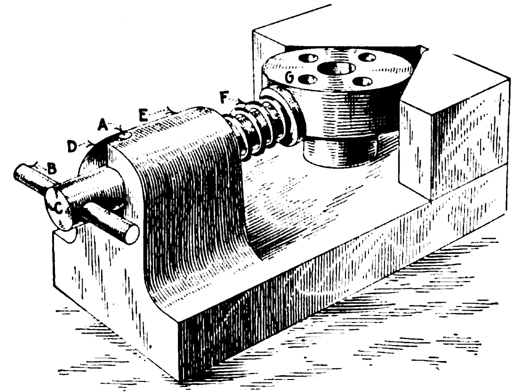
The chemical composition (percentages) of the high-speed steel tool used in these trials is as follows:

C	Si	Mn	S	P	Cr	Wo	Ni
0.61	0.10	Traces	0.01	0.023	4.49	14.45	0.31

Cam Release for Spring Plunger

By W. Burr Bennett

Occasionally, all that is necessary in a jig to hold the work in place is a spring plunger with a heavy spring, as illustrated by the piece G, in which the four small



CAM RELEASE FOR A SPRING PLUNGER

holes are drilled with a multiple-spindle drill head. However, it is somewhat awkward to operate, and considerable strength is required to compress a spring such as that shown at F. The release of the plunger C may be made comparatively easy by milling the inclined plane or cam surface D on the end of bearing E so that the pin A will follow up as the handle B is revolved. Turning the handle back to the limit will lock the plunger against forward movement.

Letters from Practical Men

Locomotive Superheater Flue Testing Machine

The superheater flues are a vital part of the modern locomotive, and in order to test them thoroughly before putting them into the boiler for service the Soo line built a testing machine on a somewhat peculiar design at its Shoreham shops.

This machine was designed by the boiler-shop foreman, M. Seraske. Its outstanding feature is that the flues are tested under actual working conditions by having the pressure applied on the outside. The general

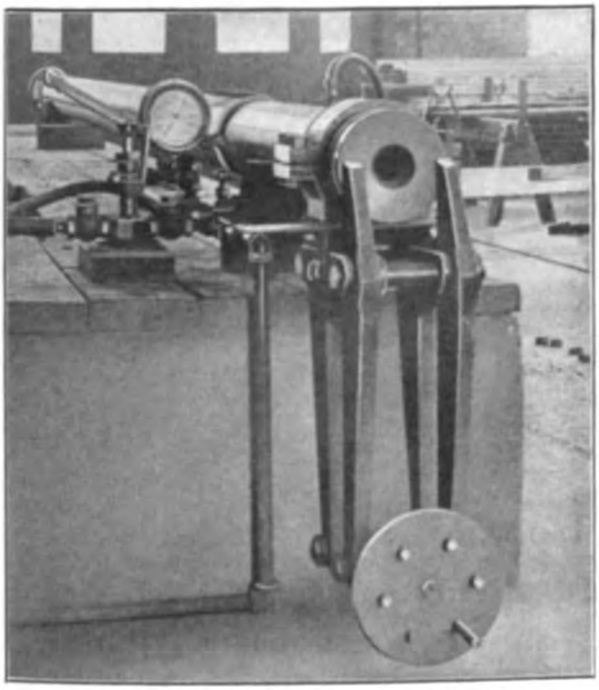


FIG. 1. FRONT END VIEW OF FLUE TESTER

appearance of the machine is shown in Fig. 1, which is a view of the front end from which the flues are inserted.

The cylinder is made of a length of 7-in. double extra-heavy pipe 25 ft. 6 in. long, the inside of which is bored out to $7\frac{1}{4}$ in. in diameter in order to provide a good finished surface for the hydraulic leather packed piston. The front end of the cylinder is closed by a removable cap that is tightened up by a substantial clamp arrangement operated by a screw and handwheel shown at the bottom of Fig. 1. The piston in the back end of the cylinder can be fitted to extension pieces of suitable length, so as to take care of flues from 12 ft. to 25 ft. long. The ends of the flue and also the front end of the cylinder are sealed water-tight by hard rubber rings that are inserted in the cylinder cap and the piston.

After a flue is placed in the cylinder and properly tightened up, the space around the flue is filled with water by simply opening the cock shown on top at the front end of the cylinder. After the cylinder is filled, the pressure is run up by the little hand pump on the left in Fig. 1. The flues are tested at a pressure of about 450 to 500 lb. per sq.in. With this pressure on, the inside of the flue is inspected for leaks through the opening in the cap. An electric light is fastened in a similar opening in the piston on the other end of the flue, Fig. 2. In this manner any leak is readily discovered and welded afterward by the acetylene method.

This machine paid for itself in a short time. Three men can test a set of 34 flues in about $2\frac{1}{2}$ hr. In an old set of flues where numerous pit marks have been welded it is necessary to test the soundness of the welds, as even with the greatest care a flaw is sometimes developed near the point of welding. If these flues are set into the boiler without being tested, it often happens

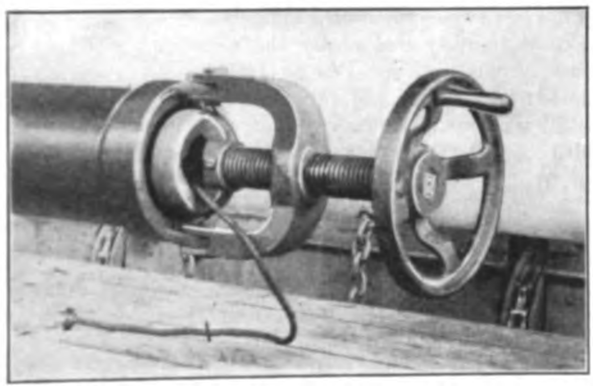

FIG. 2. REAR END WITH LIGHT CORD

that from one to six or more flues have to be removed on account of leaks. The cost of removing and replacing one leaky flue in a boiler is greater than the cost of testing the whole set in the machine described.

Minneapolis, Minn. WILLIAM SEELERT.

The Story of the Berry Baskets

This story teaches the zeal with which Dr. Stratton seizes every opportunity to foist the metric system on the people of this country and the devious methods to which he is prepared to resort in order to accomplish his purpose.

Several Northern states have laws making the dry quart the legal measure for berries and small fruits, the offering of such commodities in baskets of other capacity being illegal, and those so offering them subject to a fine. Some of the Southern states have no such laws, and early strawberries are hence shipped to Northern markets in baskets of smaller capacity, which baskets, while legal at the point of shipment, are illegal at the point of consumption. To remedy this anomalous and troublesome situation, a committee of

produce dealers endeavored to obtain the passage of a law at Washington making the dry quart the only unit of measure for small fruits and berries throughout the country. Upon applying to the authorities at Washington, they were referred to the Bureau of Standards, whose officials framed for them a bill which was subsequently introduced by Senator Lodge of Massachusetts. On cursory reading, this bill seems to be framed to accomplish its intended purpose, but closer examination shows the following little joker within it, due to action of the Bureau of Standards:

Provided that nothing in this act shall prevent the sale of such small fruits and berries by weight or by the liter, half liter, quarter liter, or multiples of the liter.

Not many of our readers will recognize the manner in which the bill, if it were to become a law, would act, but when it is recalled that the liter is about 10 per cent. smaller than the dry quart, it will be seen at once that, since no dealer could afford to use a large quart while others were using a small one, the effect would be to make the liter the actual standard. In other words, while the ostensible purpose of the bill was to make the dry quart the standard, its actual effect would be to make the liter the standard.

In explaining the matter the associate physicist of the Bureau frankly stated: "We would not care to frame a bill that would in any way interfere with the metric system," and, since no weights-and-measures bill can get past the Committee on Coinage, Weights and Measures without Dr. Stratton's approval, that was equivalent to telling the country that no weights-and-measures reform which does not bear the metric label is possible. In this case a most sensible and much needed reform was blocked by the attitude of the Bureau. They have shown themselves willing to legalize the confusion of a double standard if they can accomplish their object, which, first, last and all the time, is to get the metric system in. The grotesque legalizing of two units of measure for the same purpose and the legalizing of the liter for a single purpose shows their professed aim of "uniformity" to be a sham.

F. A. Halsey.

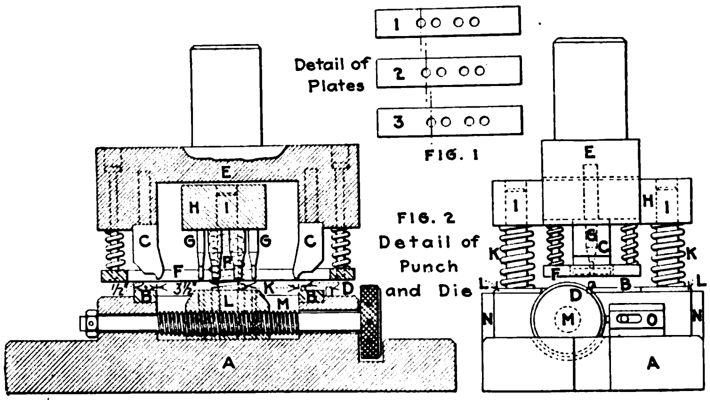
New York City.

Combination of a Press and a Subpress

In punching very accurate plates in which some holes or grooves move up a few thousandths of an inch for each following plate, as shown in Fig. 1, it has been customary to divide the job into two operations. A more recent method was to provide the die block and holder with the punches for the shifting holes, with screws to displace them; but as it stands to reason that the boy who runs the press will forget, once in a while, to turn both screws, the mechanism was often out of repair. The latest method is a union of the two previous ones, by combining two dies, the movable one being the subpress of the fixed part, as will be seen in the illustration, Fig. 2.

The bedplate *A* carries the shear blocks *B*, which in this particular case were ½ in. wide and 3½ in. apart. The parting punches *C* are shaped so that they can be turned the other way to cut on the outside of the blocks, making it possible to blank 3½-, 4- and 4½-in. plates without extra expense.

The parting punch is for trimming the material on the stop side. The disappearing stops *D* are to prevent too much waste, but the accuracy of the piece does not require them. The trimming is an insurance against any mistakes. Besides the parting punches the punch holder *E* also carries the stripper *F*, which flattens the thin material. The slot in the center of the stripper is so shaped that it allows free passage to the punches *G*. The holder *H* of the movable punches is kept in



COMBINATION OF A PRESS AND SUBPRESS

position by two pins *I*, over which the holder can slide up and down, the holes being a close working fit. Two stout springs *K* press the holder *H* against the main punch holder *E*. The guide pins *I* are rigidly placed in the movable die block *L*, which can be moved by the screw *M* between the guide plates *N*. The screw has its bearings in the bedplate. The head of the screw is divided, and turning is prevented by a snap-catch.

To safeguard against mistakes in assembling, the moving punch holder is furnished with a numbering stamp *P*, which makes only an impression in the punchings. The stamp has to be changed for each new lot of punchings.

Jan Spaander.

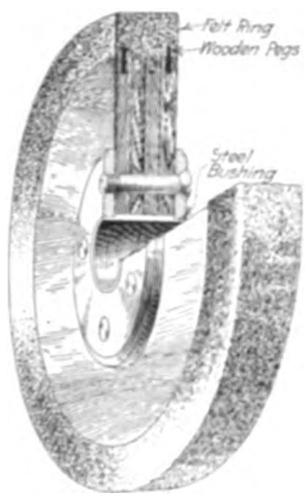
Brooklyn, N. Y.

Felt Polishing Wheel

The illustration shows a type of polishing wheel that has many advantages over the ordinary leather-faced kind, the most important being that it will cut faster and retain its emery coating longer than the ordinary wheel, and it will not glaze as easily. It was originally designed for finishing aluminum and other soft-metal castings, and for this work it is superior to every other type of wheel. It will, however, give excellent results on all kinds of metal, and most workmen prefer it to the leather-faced wheel.

As will be seen from the illustration, this wheel has a thick felt ring mounted on a wooden wheel body. The felt ring must be continuous and should be made of

rather hard hair felt. The body is formed by several thicknesses of wood glued together and so arranged that adjacent layers have the grain running in different directions. To prevent the hole from wearing out of true, it is provided with an iron or steel bushing. The bushing is held in place by a pair of iron disks, which also serve to strengthen the wheel and prevent the clamping nuts from digging into the wood. To mount the felt ring satisfactorily, the wheel body should be made large enough to require the ring to be forced on. Before the ring is put in place, the cylindrical face of the wheel body and the inner face of the ring should be coated with hot glue. The ring should then be put on as quickly as possible. To aid in holding the felt ring in position, steel wire brads may be driven through the felt into the wood, or holes may be drilled and wooden pegs driven in. The brads or pegs should not penetrate more than one-quarter inch into the felt ring.



A FELT WHEEL WILL NOT GLAZE EASILY

Before the emery coating is applied, the wheel should be trued. This may be done in a lathe, the wheel being placed on a mandrel and the high spots on the felt ring removed by a coarse file. The emery coating is then applied in the same manner as in the case of a leather-faced wheel.

The most convenient size of the wheel is 15 in. in diameter, the diameter of the body being 12 in. and the thickness of the felt ring $1\frac{1}{2}$ in. The wheel may be of any width required, and the felt ring may be rectangular, triangular, or half circular in cross-section, as desired. The proper cutting speed for a polishing wheel is 6,000 to 7,000 ft. per min., or 1,500 to 1,800 r.p.m. for a wheel 15 in. in diameter. G. A. ANDERSON.

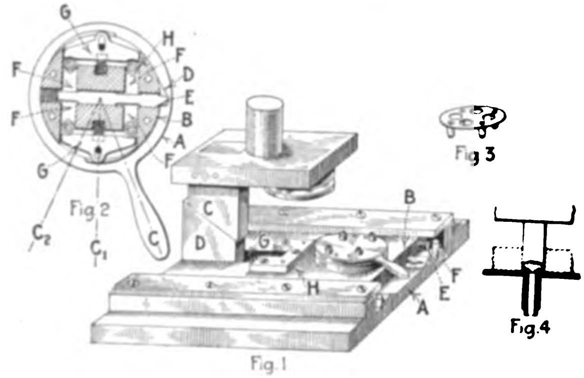
Buffalo, N. Y.

Riveting Studs in a Plate with Safety Dies

The accompanying illustrations are views of a safety riveting die for the piece shown assembled in Fig. 3. In the design of this die two things were kept in mind—the safety of the operator and preventing the parts to be riveted from sticking in the die after the operation.

The assembly of the die is shown in Fig. 1, which clearly brings out all the parts in their respective places. In this illustration *A* is the base plate, in which the die plate *B* works as a slide through the beveled fingers *C* and *D*. With the punch descending, the die plate is made to move under the punch, carrying with it the piece to be riveted. With the upward motion of the punch the finger *D* is released, and the springs *E*, fastened to studs *F*, draw the die plate back to its original position. Finger *C*, by moving into the slot *G* and guide *H*, serves also as a lever pin for the die.

The fixture for the die is shown in Fig. 2. A ring *A* is mounted on the pad *B*. By bringing handle *C* into position C_1 the cam *D* moves the gage pin *E*, which gets the jaws *F* into proper position. By moving the handle into position C_2 the clamps *G* press upon studs *H*, thereby holding them in place during the operation. Moving the handle back to the position *C* releases the studs and enables the riveted piece to be taken out without trouble.



DETAILS OF A SAFETY RIVETING DIE

The studs and the round plate are so held during the operation that after the work of the punch the swaged bushings cannot stick in the die. A. O. ALEXAY.

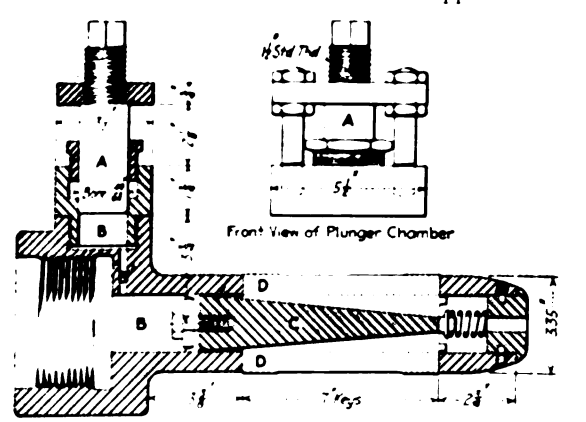
Avenel, N. J.

Hydraulic Expanding Mandrel for 4.5-In. Shells

The accompanying drawing shows a mandrel for holding the 4.5-in. British high-explosive shells while machining the outside. This mandrel will be found useful when the air-operated mandrel cannot be used on account of the lathe not having a hollow spindle.

The operation of the mandrel is obvious from the drawing. The ram *A*, when screwed down on the oil in the chamber *B*, forces the taper member *C* forward, expanding the blades *D*.

The idea of using hydraulic pressure on an expanding mandrel is a new one to me and would appear to have



HYDRAULIC EXPANDING MANDREL

a large range of usefulness for work otherwise difficult to hold.

I am also using a similar mandrel with steel balls instead of oil for the pressure-transmitting medium. The reason for substituting the balls in this case is that

the lathe spindle is of such a design that it is nearly impossible to get an oil-tight joint between the mandrel and the lathe spindle. In order to use the steel balls it will usually be necessary to increase the total length of the mandrel. This makes a longer overhang of the work, so that the oil is the best where it can be utilized.

New Glasgow, N. S. JOHN S. WATTS.

Efficiency in the Pattern Shop

We hear a great deal about ways and means of reducing costs and increasing production in the machine shop or foundry. These plans are continually being brought to the attention of the management of enterprising concerns, but seldom is anything said of the savings that could be effected in the pattern department. Few managers realize the unnecessary expense and delays in production that are caused in the pattern department by not having it in closer touch with the drafting room and the foundry. Costs mount up in the pattern shop for several reasons, but under better conditions could be greatly reduced.

In the first place too little consideration is given in the drawing room to the design of machine parts that are to be cast. Very often the construction of the pattern could be simplified, thereby reducing costs and in a great many cases further decreasing the expense in the foundry without affecting the design of the machine or part.

Frequently machine parts are designed with pockets, projections or undercut portions that make it necessary for the pattern maker to core out under these parts in order to get a casting true to the drawing. This means extra work in the pattern shop and foundry and produces a rough casting, because the drawing room does not consider or does not understand that the design means extra work in patterns and foundry.

Sometimes a drawing goes to the pattern shop for work that is still in the experimental stage. Unless orders pertaining to it are given, the shop makes up the pattern in first-class manner when a much cheaper pattern could have been made to give the casting wanted.

Too often the foreman of the pattern shop thinks that he knows the best way to mold patterns and makes up some complicated work without talking the matter over with the foundry foreman. When the work is received, the foundry foreman refuses to accept it until it has been changed to suit him, and these alterations entail extra costs and delay. Often a pattern is made for a broken part of a machine, when the piece itself could have been sent to the foundry and used for making a mold without further cost.

An example of how these things sometimes get by and run into money recently happened in a fair-sized shop. The machine foreman in rigging up an old lathe for a special job found that the faceplate, which was of cast iron, was cracked on one side. Instead of sending it to a near-by shop to be acetylene welded, he took it into the drawing room to have a sketch made for a pattern. The foreman of the drafting room gave it to one of the boys, who made a standard-sized tracing, all lettered. A blueprint was taken and the pattern ordered. The pattern shop upon receiving the blueprint and order made up a first-class pattern which in a couple of days was sent to the foundry with an order for one casting. The pattern was supposed to be for production, and three castings were made. A week's delay and an excess in costs in all departments that handled this part were incurred because the piece was too small to have much thought given to it.

Thousands of dollars could be saved yearly in large concerns by having an efficiency man—a practical patternmaker—work with the drawing room, pattern shop and foundry, to help them to coöperate. He would show the drafting room the needs of the pattern shop and the foundry, so that the designs might be simplified where possible. He would see that proper patterns were ordered and would consult with the foundry regarding the best method of making patterns. With such a system the work would be carried through with the least delay and the lowest costs. JOHN J. EYRE.

Boston, Mass.

New York Preparedness Parade

The greatest parade in the history of the country, if not the world, was reviewed in New York, May 13, by Mayor Mitchel, Major General Wood and Admiral Usher. The parade was composed of civilians representing 64 trades or professions. It started at 9:30 in the morning, and the last platoon passed the reviewing stand at 9:40 in the evening. At no time was there a break in the line of more than three minutes' duration.

A careful compilation of the number of marchers, made with indicators by representatives of the New York *Times,* fixed the total at 125,683, made up as follows:

Male civilians (excluding bandsmen)	105,674
Women	3,287
National Guardsmen	7,994
Spanish War Veterans	728
Bandsmen	8,000
Total	125,683

This exceeded by 45,000 the largest parade that had ever been given previously, the Sound Money Parade of 1886, and exceeded by 50,000 the Business Men's Parade in 1908. Over 60,000 men had to be refused enrollment because of the inability to pass more than the above number by the reviewing officers within the alloted time.

There were no uniforms, no wheeled vehicles, and no horses except in the National Guard and those used by the Grand Marshal and his staff. But although civilian clothes were worn, almost every marcher carried an American flag, which, besides the battalion colors, made a sight impressive beyond mere superlatives.

The purpose of the parade was to impress upon the country at large, and to the pifflefists in Congress in particular, the overwhelming sentiment for preparedness.

There were 7,000 engineers in line, marching in platoons of 20, each platoon with a leader, and they without any doubt presented the finest appearance of any body of men in line and earned many plaudits from the 1,000,000 spectators who lined Fifth Ave. during the entire 12 hours.

They were led by the Naval Consulting Board, composed wholly of engineers from the national engineering societies. Then followed the delegation from the Engineers' Club; then the other engineers.

It was the first time the engineers of New York ever appeared in a body, and it was a most significant event in many ways. When W. L. Saunders, Thomas A. Edison, and many others will march afoot in the ranks of such a demonstration, it betokens a depth and weight of public opinion which ought to have an effect even on a Congressman.

Discussion of Previous Question

The Suggestion System

On page 561 I noticed with special interest the points raised by J. H. Davis on the suggestion system. I have had experience with suggestion schemes and am strongly in accord with his views. I think every practical man must be in agreement regarding adequate compensation to workmen for suggestions that are accepted by the employer. Also, I agree that, when any individual workman is frequently introducing ideas, he is undoubtedly "worth watching." Sometimes this type of man receives compensation for his ingenuity by being promoted to an official position. Unfortunately the new place is not always so remunerative as the old job. Consequently, this method of compensation has a tendency to make some operators withhold some of their ideas. Many consider the present time only instead of looking to the future, when sooner or later they would have a chance at a bigger job with more money.

Of course, there are some men who take into consideration the title that goes with an official position. But my experience with the average operator is that titles are not usually desired. They do not pay the various household bills.

With regard to suggestion schemes for the small firm, they should be encouraged as much as in a large plant. Instances could be cited where the small shop has aroused itself from the go-as-you-please-way to that of an "up-to-the-minute-shop" through the introduction of an efficient suggestion system. In fact, the system is often of most value when it is adopted in connection with a small firm, because the men pull together and everyone does his best to turn out work efficiently and smartly when his ideas are readily accepted and put into operation. The small-shop foreman, however, must always be ready and willing to listen to the men and should solicit suggestions, because by so doing he will create a spirit of cooperation that is so essential.

A. Eyles.

Manchester, England.

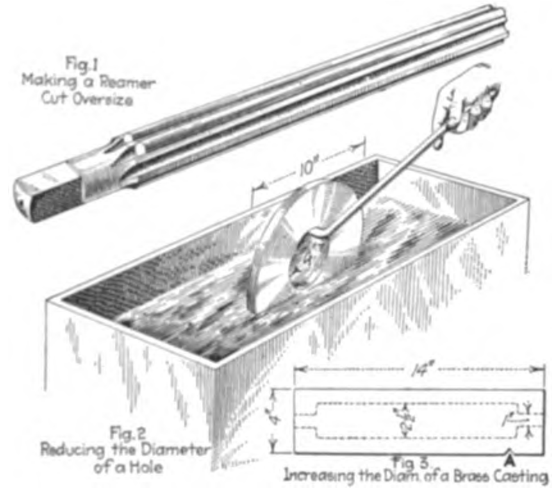
From a Small-Shop Notebook

I have read with interest J. H. Van Deventer's "From a Small-Shop Notebook," on page 588, and would like to submit a few kinks that may also be helpful to small-shop mechanics.

There is another way than the one shown to make a reamer cut larger. This method is to take one piece or, better, two pieces of steel wire, solder one end of each to the top end of the reamer, leaving the other ends free. The size of the wire is governed by the size and number of flutes. It should be chosen to fill the space between the flute and the wall of the hole to be reamed, and adjustment can be had by shimming under the wire with paper.

At one time I had some large steel washers cut from ¾-in. boiler plate, as shown in Fig. 2. By mistake they were made 0.010 in. too large in the bore. Instead of throwing them away I put them into the furnace, heated them to a bright red and then dipped them into cold water, as shown in the illustration, cooling the outside edge first by turning the disk around quickly and leaving a ring of hot metal on the inside next to the hole. The result was that this hole decreased in size sufficiently for us to rebore it.

Mistakes are made as frequently in small shops as in large ones, if not oftener, and Fig. 3 shows a brass



HELPFUL SMALL-SHOP KINKS

casting in which during the finishing cut on the outside diameter the tool dug in as at *A*. The piece had not been faced to length, so by putting it under a hydraulic press and squeezing it endwise we were able to swell it enough to grind the diameter and get rid of the gouge.

Holyoke, Mass. JOSEPH G. NOBLE.

Truing a Lathe Center Without a Center Grinder

On page 821 is shown a method of truing lathe centers without a center grinder. This method is open to criticism. I tried it some 12 years ago and found it wanting. Roughing a center by hand so that it will run within $\frac{1}{64}$ in. of true is a delicate job indeed. Then lapping it with a piece of worn-down emery wheel is some task, if the center runs out true, and also takes a lot of time. It will be anything but round if the wheel is held as shown. It will also be scored unless the wheel is moved to and fro parallel to the horizontal axis of center. This can only be accomplished by setting the compound rest at a proper angle, on lathes that have one.

It does not make much difference if the dead center is sprung a little in hardening, for any error can be compensated for by adjusting the tailstock.

Ours is one of many shops that do not possess a center grinder. We use two live centers. One is hardened and used during the roughing operation. Then the hardened

one is removed and the soft center, which is turned true, is inserted for the finishing operation. I have followed this method for several years, and it leaves nothing to be desired. G. STROM.

Brooklyn, N. Y.

Proposal to Standardize Machine Tools

I was much interested in the report of the discussion at New Orleans of Mr. Miller's paper on "Industrial Preparedness." The point that interested me most was Mr. Alford's suggestion of standardizing machine-tool designs and the resolution to have a committee to consider this feature.

I understand that the idea is to prepare standard designs of machine tools (which would be principally lathes) for the manufacture of munitions and to publish these standard designs and specifications. This looks to me like a most excellent idea because shell lathes, if properly designed, are really simple things to build, and with standard designs available, they could be produced by practically any machine shop, so that even from a standing start they could be turned out in almost unlimited quantities within a few months. This would leave the regular machine-tool concerns free to produce their standard machines, which would be needed in large quantities by the machine shops that were building the shell lathes, both for making the lathes and for toolroom equipment.

I am also satisfied from experience that this would result in a great saving in cost. This is particularly true of the larger shells. We are making 8-in. shells and were offered for this work 30-in. and 36-in. engine lathes having 12-ft. and 14-ft. beds and costing from $2,000 to $4,000, equipped with regular overhead countershafts and regular engine-lathe features. The lathes we are building for ourselves are 24-in. swing with 7-ft. and 8-ft. 6-in. beds and should be produced for about $1,000.

We have done something ourselves toward standardizing shell-lathe construction. We have a standard cross-section of bed which we make in four different lengths, and we find this equally satisfactory for 3.3-in. and for 8-in. shells. We have four or five different designs of headstocks for this bed and some variations of each design adapted to different operations and various sizes of shells, but any headstock can be put on any bed. Right here I might say that all of these headstocks have cast-iron spindles with driving gear cast integral. I think the first thing the committee ought to do is to cut out any business of "hammered high-carbon steel spindles bored from the solid" and also eliminate steel gears and "semi-steel," which after all is only a polite way of saying cast iron. We also have a lot of different designs of saddles for different operations, but all having the same size of dovetails take a cross-slide. Most of these saddles take the one standard apron, which is very simple and cheap to build.

For feed we are using belt feed exclusively, and it is quite strong enough to pull two heavy cuts on the 8-in. shell, reducing it at once from forging size down to ⅛ in. over finishing size. We use standard split steel pulleys on the spindle and a rod for driving the feed, so that we can readily experiment until we get the exact feed that suits best. We use two feeds with jaw clutch between, so that we can have a roughing and a finishing feed.

We are also making thread millers that take the same design of headstock and bed as the lathes. These are double-spindle machines, so that we can true up the counterbore at the same time we mill the thread.

I certainly think that a good move is being made in suggesting the preparation of standard designs of machine tools for shell manufacture. If the Government adopts the proposition to let small contracts for munitions in times of peace, I should think it would be a good plan to arrange so that some of the large shops would make up their own machine-tool equipment for making these peace-time orders. This would insure that a number of shops throughout the country had drawings, patterns, equipment and experience for making the machine tools necessary to produce munitions.

It should be added that before this committee can get very far in their labors they will need to have before them standard designs and specifications of the shells that are to be produced, and as has been pointed out several times in the *American Machinst,* there is room for a good deal of improvement in the design of shells to make them economical to manufacture. It would therefore seem desirable to first secure the coöperation of the War Department in simplifying and standardizing the designs. H. V. HAIGHT.

Sherbrooke, Que., Canada.

Sizes of Tap Drills for Varying Conditions of Work

Perhaps the last sentence in my article on page 775 should be qualified so as to prevent any misunderstanding. Tap action is as follows: A sharp tap tends to throw up what may be termed a slight burr on either side of the cutting point as it cuts the thread in the hole, thereby slightly increasing the amount of thread contact of the screw. With a dull tap this "burr" will be more pronounced as the tap is forced through the hole, which still further increases the amount of thread contact for the screw, especially in the softer metals.

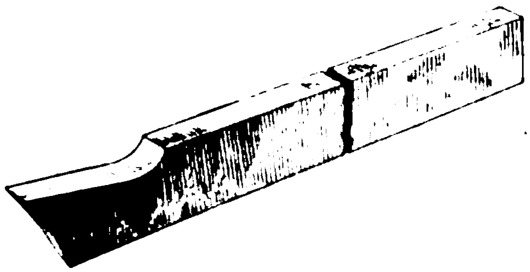
Indianapolis, Ind. O. R. KLEPPER.

Curved-Lip Parting Tool for Planer or Shaper

On page 284 Mr. Roberts illustrates a novel form of parting tool, which he has used with good results on cast iron. Equal results in either cast iron or mild steel are obtained by rounding the face of the tool as shown by the accompanying illustration. This shape has the effect of causing the chips to curl in the direction of their width and thus become narrower than the groove cut by the tool, and they will therefore clear themselves freely. It is usually recognized that the metal in the chips occupies more space than it did before being cut, with the result that, when parting with a square-faced tool, the cuttings wedge themselves in the groove, causing the frequent breakage of parting tools.

A large fillet should always be left at the root of the cutting face. Otherwise, this is the weakest part of the tool, and in the event of breakage the whole end of the tool is lost.

The remarks of Mr. Groocock on tool lubrication—page 296—are very interesting as showing the effect of different lubricants for different materials and operations. For producing a highly finished surface in relieving tool-steel gear cutters a mixture of lard oil and



PARTING TOOL FOR STEEL OR CAST IRON

turpentine may be relied upon when other lubricants fail. This mixture has also proved very successful in producing a smooth thread on tool-steel screws.

Glasgow, Scotland. JOHN HOLDING.

Glass-Cutting Experience

Referring to the article on glass cutting, on page 516, does not Mr. Little give a wrong impression as to the value of the diamond for cutting glass? The diamond as cut for finger-ring settings is about as suitable for glass cutting as the ball peen of a machinist's hammer is for use as a scriber!

My experience has taught me that there is everything in favor of a diamond glass cutter except the two facts that the diamond cutter costs more and that it is more likely to break if drawn sidewise across the glass.

The diamond chips that are mounted in the commercial glass cutters that I have used have all been small thin pieces presenting a knife-like edge to the glass. When carefully handled, they have shown a long life and have given the best of results, cutting a much smoother line than any steel-disk cutter. MYRON E. EDDY.

Rockton, Ill.

Preparing for Manufacturing Munitions in the U. S.

The letter on page 908, by A. B. Chester, has much to commend it. My only criticism is with the second paragraph. The making of munitions for foreign countries has two bad features: It supplies our possible enemies with war material to use against us, and it introduces the temptation to foment the national rivalry between countries in order to sell munitions at a large profit. The country can much better afford to pay a heavy bonus on material it needs for itself rather than have such scandals as were traced to the Krupp and other works a few years ago. Then, too, I fear Mr. Chester lays too much stress on the need for the trained mechanic on much of the work.

The making of heavy and machine guns probably requires skilled men for the most part, but this is not true in the case of shell and similar work, which forms the great bulk of war supplies in the modern battles. The majority of workers on shells in plants that are turning out the largest quantities never saw a shell before. And many of them never saw the inside of a shop before. Modern manufacturing utilizes skillfully designed machines that can be run by inexperienced men.

One great need is to study carefully the designs of shell and fuse parts in order that they may be manufactured rapidly and at minimum cost. This means paying particular attention to tolerances, to prevent their being made any finer than is absolutely necessary to have the part function properly.

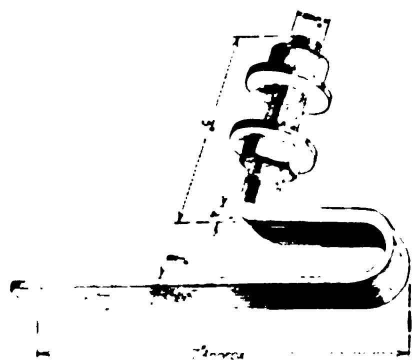
Mr. Chester's plea for the opening of the arsenals for the education of those who must make munitions in time of war is along the right line. Widespread information is of far more value than any secrecy can possibly be.

New York City. FRANK C. HUDSON.

Device To Hold Center Work to Faceplate

The accompanying illustration shows a "hold back" that is much better than the ordinary strap or belt lace. To me it appears better than two devices recently shown, one on page 188 and the other on page 203 of Vol. 44.

In using this device the $\frac{5}{8}$-in. threaded shank is inserted through a hole in the faceplate and adjusted so that the long flat spring end will have just the proper tension to hold the work in place when it is sprung over the tail of the dog. This arrangement is



A SPRING-TAILED "HOLD BACK"

very useful on production work, as the faceplate does not have to be screwed back and forth on the spindle for each piece, and it will fit any ordinary faceplate or lathe dog.

These spring dogs may be made larger or smaller, but the one shown is suitable for use on lathes of from 14- to 20-in. swing.

In removing work from the lathe it is only necessary to swing this spring dog around until it clears the tail of the lathe dog, so the faceplate does not have to be loosened. HERBERT M. DARLING.

Greenfield, Mass.

Fractions, Decimals and Millimeters

The equivalent table on page 172 suggests that perhaps my practice in handling data of this description may prove interesting.

When scrapping catalogs, I take out all data or tables and put between the covers of an old catalog the clippings

that I am likely to want immediately. These data sheets are trimmed to a standard size of 4x7½ in., the cover being about 4¼x7¾ in. The sheets are entirely loose; an elastic band around the covers keeps them together.

Should I go to another shop, perhaps I should need different data. The data sheets that I do not immediately use I keep in stock in an envelope. If I have the matter there, I can remove from the book any data that I do not require, put the sheets back in the envelope and insert new data in the book.

By this method I can locate your table of equivalents of metric and English units in a few seconds.

Wembley, England. J. H. Davis.

Side Shield for Emery Wheels

On page 606 is a query about the objection to the use of the side of emery wheels. The chief reason is that the nature of the material and the shape of the wheel do not enable it to withstand much pressure in this direction with safety, as the wheel is placed under bending strains. When the face is used, the wheel is under compression, to which it is more suited.

As the popularity of the side of the wheel is due to the same reason as that of the disk grinder—the ease of obtaining a fairly true surface without exercising great skill—it follows that the side is used chiefly for the larger surfaces. Now in order to save time and get the same unit pressure a workman will employ greater total pressure than he would on the face, which is just the reverse of what ought to occur.

I have seen wheels worn down nearly to a V-edge by this practice, spoiling the face for most uses. The thing to do is to install a disk grinder—even a small one using 9-in. emery cloth will be found a remarkably handy tool.

As the side of a wheel seldom gets a truing-up, articles ground on it are likely to appear flat when they are not, since the wheel shows a bearing all over the work.

Rochester, N. Y. S. E. Cory.

Blueprints Without Tracing

Mr. Spalding, on page 803 of the *American Machinist*, writes about making blueprints without tracing. I, too, have taken advantage of the fact that very good blueprints can be obtained from drawings made on bond paper with a soft pencil. Light-weight but very tough bond paper was selected. The scheme was found to have disadvantages as well as advantages. The lines rub off very easily, since a soft pencil must be used; and if the drawing is handled very much, it soon becomes smeary and dirty. Such drawings cannot be cleaned with art gum, as can ink tracings.

These pencil drawings are good and economical for such work as jigs and fixtures, where only a few blueprints will be made. The method is also satisfactory where an experimental model of a mechanism or machine is to be made. The drawings can readily be modified as the work of experimenting and testing reveals necessary changes and alterations. Notes can be written upon these drawings; and when the final mechanism or machine to be manufactured is decided upon, they can be used as a guide to make the permanent tracings, after which the pencil drawings are discarded.

Mr. Spalding also states that the usual method of making drawings to be reproduced by blueprinting is to transfer a pencil drawing on heavy paper to tracing cloth or paper, but such has not been my experience. I have designed a number of small, although rather complicated, mechanisms, but have never found it necessary to make pencil drawings of the details before making the final drawings on cloth. An assembly drawing was accurately made on heavy paper with a hard pencil. When the details were to be made, a few light guide lines were made on the tracing cloth with a soft pencil and the drawings made immediately in ink. I have found that such work does not require the service of a draftsman who is exceptional or out of the ordinary.

Middletown, Ohio. W. E. Sharkey.

Sponges That Only Absorb

The article on page 759 is fortunately true of only a small portion of the mechanical fraternity. One of the greatest pleasures in life is telling the other fellow how you thought out some little kink or saved time in doing a job. What a poor place this world would be if there were no chance to tell what you have done or if none of the wise ones could get together and talk over or publish their experiences for the benefit of the rest!

Where would the mechanical world be today, if men like dear old Professor Sweet, or Taylor, or hundreds of others had kept their knowledge to themselves? I imagine that our Eastern friend mentioned by Mr. Godfrey could have given Mr. Middle West a few more valuable hints on how to make munitions, had he but walked through the shop to see how the work was being done.

In all my experience in shop and factory I have never refused to tell a man what I knew about the work he was doing. This has never cost me a cent; but on the other hand, I feel sure that I have gained fully as much as I have given. It all broadens the mind, improves the capacity to think, brings out other ideas, makes friends, helps the other fellow and brings back to you information that you would not otherwise receive. Our Eastern friend has my congratulations on the way he handed it to Mr. Middle West, who I hope will profit by the experience. George G. Little.

Rochester, Minn.

Lapping Holes in Steel

On page 778 N. J. Miano tells his experiences in lapping out casehardened steel bushings. A lead lap is a poor tool with the best of lapping compounds, and with turpentine it is almost impossible to do good work, as this combination produces a sticky, black mass with poor cutting qualities. Even with brass a quick wearing away of the lap material is usually found.

Far better results can be obtained with a coarse-grained, soft, gray-iron lap with a suitable expanding device, using No. 1-F carborundum mixed with a good grade of lard oil to the consistency of a thin paste. The lap should have a number of grooves running longitudinally to retain the lapping medium.

New Britain, Conn. William C. Betz.

Editorials

Changes and Future of Russia

For many years Americans have ignored most foreign markets in favor of the excellent one at home. But the war has brought to our manufacturers a realization of the extent of the oversea opportunities, and headway has already been made in reaching out for foreign trade, particularly in South America.

The Russian market also offers great opportunities to American machinery builders, but is a field that requires careful handling and close study. Interest in its condition and possibilities is rapidly increasing among manufacturers.

The Empire of Russia comprises one-seventh of the land area of the globe; its population is about 170,000,000, the density being about 20 per square mile. (The density in the United States is 33 per square mile.) In 1861 the 20,000,000 Russian serfs were emancipated, which was the first great step toward democracy.

Since that time measures have been taken to place the peasants in the position of independent producers, principally of agricultural products. Russia's industrial advance has been impeded by the religious fervor of the masses, most of whom looked askance at Western industrial development as bringing in its wake all the evils of which their rural life was particularly free. In spite of this the influence and prestige of the manufacturing classes continued to gain headway, until just prior to the war Russia's imports amounted to $700,000,000 per year, or a per capita of about $4.

While Russian tastes are simple, as is commonly the case in communities that are largely rural, the war has effected and is effecting tremendous changes, not only in wants, but also in character and education. The war has brought to Russia many German and Austrian prisoners who, to while away the time, have eagerly grasped the opportunity for manual labor and have taught the rude peasant some of the modern ways of doing things. Similarly, Russian prisoners in Germany have been employed in all kinds of skilled and unskilled labor. Here they have learned the advantages of systematic order from the world's most successful organizers and have gained knowledge that will have its effect on Russia in the years to come.

It is impossible to belittle the marvelous change that this enforced education of the Russian masses will cause in the needs for manufactured articles of these 170,000,000 people. Familiarity with the conveniences of a higher civilization has invariably caused a desire for, and determination to continue to enjoy, such conveniences. The sentiment behind the remark of a high Russian official, to wit, "We ought to make the Kaiser a saint in our church, on account of the blessings this war has brought to Russia," can be easily understood.

At the beginning of the war Russia spent $500,000,000 for vodka, the national drink. An imperial manifesto ordering prohibition has given Russia increased buying capacity to this amount in addition to a marked increase in personal efficiency and output of labor, with its consequent further increase in purchasing power.

There is a strong economic resemblance between Russia and the United States, and the historic friendship between the two nations should prove of valuable assistance in the efforts of American manufacturers to get their proper share of Russia's foreign trade. As has been stated, Russia now imports about $700,000,000 worth yearly. These imports may some day reach $3,500,000,000 yearly, based on the American imports under similar conditions.

The main feature of the Russian market lies in newly acquired tastes of a virile, energetic population. The prospect is indeed alluring.

Reasons for Strict Government Inspections

There are so many phases to the problem of inspection that it becomes a most complicated question. It is difficult when we must guard against accidental or unintentional mistake only; but when we are obliged to draw specifications so as to cover all attempts to "put over" inferior work or material, it is not only more difficult, but inflicts hardships on those who have no intention of being dishonest. This penalty, unfortunately, occurs with almost all rules and laws—those innocent of intent too often suffer with the guilty.

This maxim is particularly true in the case of government specifications. Without excusing many of the hardships imposed upon innocent parties by the inflexible inspection and penalties for delays, we must not overlook the fact that these rulings are the direct result of dishonest dealings in the past. It is unfortunately part of the shameful history of every country that unscrupulous men have not only supplied inferior material for profit, but by their cupidity and greed have sacrificed thousands of lives which were being given to defend their very property. So the many suffer by rigid rules because of the baseness of the few.

Government inspection, as with all other inspection, must be strict, so far as the inspector is concerned. Any discretion leaves him open to influence of one kind or another. There should, however, be a man higher up, with sufficient judgment and authority to say what are allowable variations from standard. Such a man should have authority to remit unjust penalties, just as would be done by a reputable concern in private business. This function cannot, however, be intrusted to a $1,200-a-year clerk or to a political appointee, but must be given to a man with due sense of his responsibility, receiving a salary that removes ordinary temptation.

We all know the faults and frailties of government inspection, specifications and employees. But we too often forget that, in the United States, we, as private citizens and as business men, are the responsible parties. When we come to realize that "the Government" is not a thing apart, with all kinds of money to spend and a

legitimate prey for all, but that it is our Government, that we as individuals pay every cent that it spends, we will come nearer to having it run as it should be. Then, and not till then, shall we have rational inspection and penalties. Then can red tape be laid away and quick action and results be secured.

There are many who have had unpleasant and unprofitable experiences with Government contracts, owing to a variety of causes. Many are naturally resentful and refuse to bid on Government orders. Some even go so far as to say that the Government can go hang before they will supply any more machines for the arsenals. But these men do not realize that the Government's use of those machines is for their protection; that we are so bound together that the injury to one concerns all.

It is of no use to try to imagine that the Government is run perfectly. No government ever has been, and probably none ever will be. But it is our Government. We are a part and parcel of it. We pay the freight, and it is up to us to try to make it better instead of saying we do not want to play the game.

We must remember that the Government is not a political party, no matter who happens to be steering it at the moment. It is the mechanism we have constructed so that we can attend to the business of earning a living. If the mechanism is faulty, let us redesign and rebuild it.

A Criterion of Honesty

A number of years ago the leading financier of the country made the statement before a Congressional committee that money is loaned on character and not on collateral. While we should not expect a Federal bank examiner to be governed literally by this dictum, any banker will agree that the best security for a loan is the integrity of the borrower.

The most important rule of conduct for the business of life is taught every child as an exercise in penmanship—"Honesty is the best policy." It is in fact taught so early that the words mean very little when they are first learned. As children we take for granted that honesty is the best policy. It seems rather unnecessary to make so much fuss over such an obvious statement. Honesty at that age means not to lie for gain, not to steal and not to murder. Being honest looks easy. It is only after we have been in the hurly-burly of competing for a living that some of the maxims learned early in life are revealed in their true meaning. Honesty becomes a new word, not so susceptible of exact definition as we thought. The problem of choosing the honest course of action is sometimes very complex. Only the finest line may separate the honest from the dishonest course.

The young man is fortunate whose powers of discrimination are naturally keen (it is often only a good sense of values that leads to the right decision where the question is complex, and not necessarily superior moral integrity) or who has good advisors to guide him in solving his early perplexing problems. Each correct decision helps, however, to weave the fabric that eventually becomes the habitual garment of the man of character. The cynic will say that strict honesty demands sacrifice of self-interest and is therefore not compatible with material success. This is the saddest bit of sophistry of all. The statement to which we have alluded bears witness to that.

There is no truer criterion of the honesty of an employee than unswerving loyalty to his employer. This is an application of the policy of honesty which young men sometimes fail to make. Loyalty and whole-hearted allegiance to the cause in which we are engaged are the factors that very largely determine our ultimate success.

The Tavenner bill in Congress, to prohibit time study and payment of bonus in all Government plants, is not likely to pass. But the danger from the attempt has by no means gone. The next attack may be expected in the nature of riders to the four great appropriation bills—army, navy, postal and fortifications. These riders when offered, following the precedent of last year, will prohibit any money appropriated in the bills from being used for time study and bonus payment.

Of course, the next step is easily foreshadowed. It will be an attempt to establish the same prohibitions on all Government work done in private plants. Such Congressional action will also be pointed to as proof of the iniquity of the great movement for industrial progress.

The Bureau of Foreign and Domestic Commerce in a press notice quotes approvingly from its special agent, J. A. Massel, as follows: "It is evident that, if one excepts agricultural machinery and possibly a few other lines of minor importance, the American manufacturer has thus far had virtually no market in Argentina for his products in general and for machine tools in particular." That is, ". . . . if one excepts agricultural machinery . . . the American manufacturer has . . . no market in Argentina . . . for machine tools. . . ."

American machine-tool builders will be pleased indeed to know that "agricultural machinery" is machine tools. And what will they think of the reliability of the reports of a "special agent" who writes such an impossible opinion?

As a matter of fact, 40 per cent. of the machine tools in South America were made in the United States. Ninety-nine per cent. of the machines in the largest machine shop in that great continent—the Tafi Viejo shops of the Argentine State Railways, with 5,000 employees—are North American.

A correspondent of the *American Machinist* called attention to the trouble of his agent in Uruguay over some descriptive literature sent down from the United States. The difficulty arose because the weights and measures given were in English units and the origin of the matter was not stated. A letter from the Uruguayan consul in New York clears up the law in the matter. It reads:

"In answer to your communication of the 21st inst., I beg to inform you that according to a Decree signed by the Minister of Industries of Uruguay on Sept. 25, 1915, the law of Oct. 2, 1894, making unlawful the circulation in Uruguay of catalogs and other printed matter where weights and measures other than those expressed in the decimal-metrical system are mentioned has no bearing and does not apply to catalogs and other literature printed by foreign firms in foreign countries."

The point to remember is that catalogs and other printed matter intended for circulation in Uruguay and containing matter expressed in English measures must also state that they were prepared and printed by foreign firms.

Shop Equipment News

Screw Header Supplied with Friction Feed

The primary advantage of the friction feed on the header shown in Fig. 1 is that exact length of stock can be fed at each stroke of the feed lever. This is not possible with the ratchet feed, as the surface of the ratchet cannot be spaced to suit all different lengths of blanks, which results in a waste of stock in imperfect blanks. The friction device, shown in Fig. 2, enables the feed to be regulated, while the machine is running, to give just the amount of stock necessary to make a perfect head without fin or flash, provided, of course, that the punches and dies are in good condition.

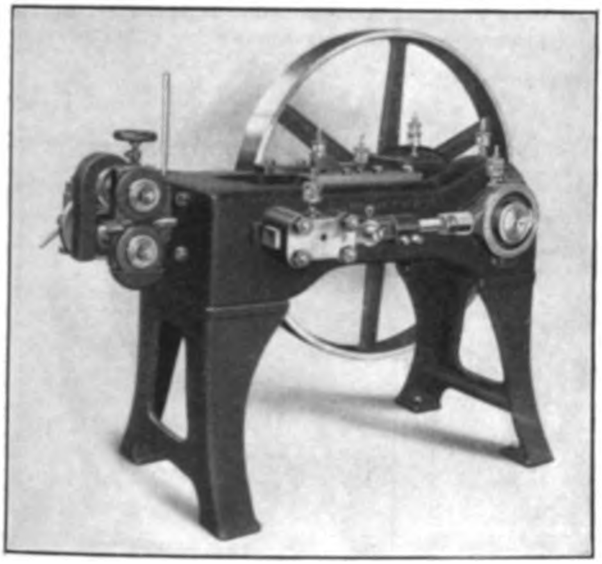


FIG. 1 SCREW HEADER

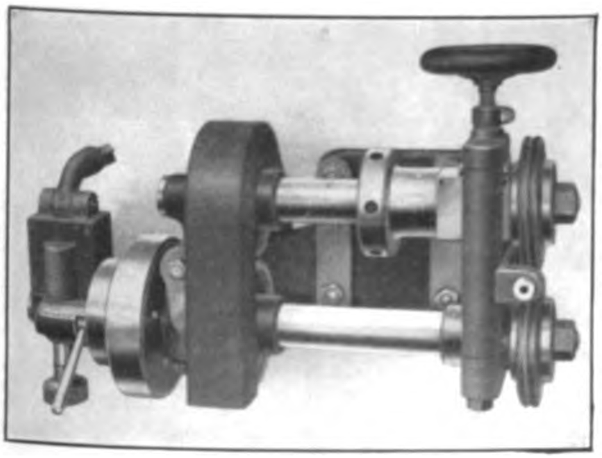

FIG. 2. FRICTION FEED OF HEADER

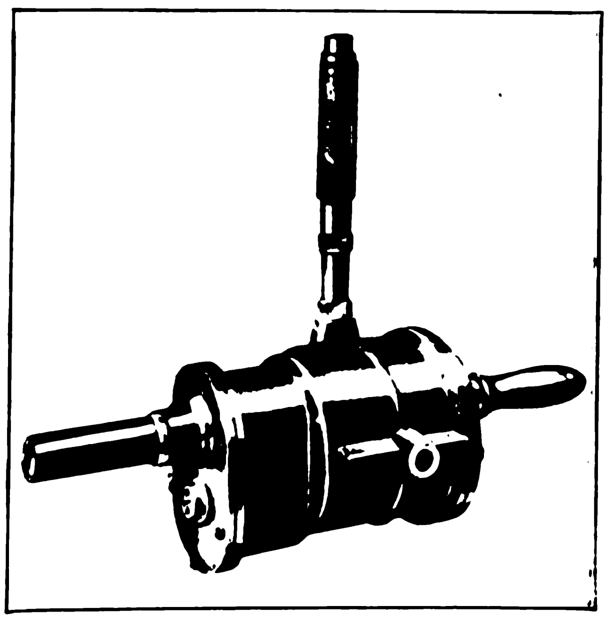
Using just the right amount of metal instead of a surplus, as is customary to insure full heads, relieves the pressure on punch and die and increases their life. It also relieves the stresses on the machine. The operator can start and stop the feed as well on the back stroke of the feed arm, doing away with the making of shorts on bung heads. The friction is adjusted to slip with unusual strain, avoiding breakage in case the blank sticks in the dies.

There is no stop on this machine. This saves wear on the feed rolls, caused by setting the stop to feed too much wire and then letting it slip, soon wearing the rolls out of round and necessitating frequent replacements. The cutoff is so constructed that it does not operate as long as there is any pressure on the punch. This arrangement saves the wear from excessive friction, which is more than many seem to realize.

These headers are made by the Asa S. Cook Co., 605 Franklin Ave., Hartford, Conn., which makes five sizes of both solid- and open-die, single-blow, cold-heading machines.

Portable Pneumatic Tapping and Drilling Machine

The machine shown was designed for tapping holes for stay-bolts and screwing bolts into place in all kinds of firebox work. It may also be used for drilling and reaming holes in other work up to $1\frac{1}{4}$ in. in diameter.



PNEUMATIC TAPPING AND DRILLING MACHINE

With a working pressure of 100 lb. it runs at a speed of 175 r.p.m. and develops $2\frac{1}{2}$ hp. When used for rolling boiler tubes, it will roll out a complete set of

three hundred $2\frac{1}{4}$-in. boiler tubes, including both ends, in 6 hr. It is composed of but nine parts—gears, throttle handle and all. The total weight in working order is 28 lb., and it is made by the Baird Pneumatic Tool Co., Topeka, Kan.

Special Shell Equipment

The illustrations herewith represent a line of special shell-making machinery developed by Horne, Dale, Brown Co., Chicago, Ill. In addition to the machines shown there are incorporated in the complete line a cutting-off machine, a banding machine and stamp rolls, thus providing complete machining equipment for shells ranging in size from 3 to 12 in.

It will be observed that the machines are of the single-purpose type and heavily proportioned. The designs were worked out in a large munition-manufacturing plant and were adopted as marketable products only after meeting the exacting requirements of shell production.

The roughing lathe, Fig. 1, has a long hollow spindle and powerful driving mechanism. The tailstock has a double spindle, one operated by a double-pitch screw for fast travel and the other by a five-pitch screw for tightening. The machine has three traverse feeds and three crossfeeds. Provision is made for hand feeding in both directions. All gears in the apron are of steel, except the worm gear, which is of bronze.

Two roughing lathes are used. The first roughing lathe, shown, rough-turns the diameter and rough-faces. The second roughing lathe, not shown, takes the second roughing cut on the diameter, finish-turns up to the end of the band groove and finish-faces the end.

The only difference in the two lathes is that the first roughing lathe has gear reduction on the spindle and has a drive pulley and pinion running on a stationary bearing, while the second roughing lathe is driven direct by a pulley on the spindle.

The grooving machine, Fig. 2, grooves, undercuts, waves and forms the radius on the end of the shell. The machine is driven direct from the lineshaft and is started and stopped by a jaw clutch on the main-drive pulley. Two tools are used, one in front and one in back of the tool carriage. The operator can use either power or hand feed when grooving, and the front tool waves and forms the radius. Stops enable the operator to get all distances exact without the use of hand gages. A swinging stop located on the tool carriage locates the base end of the shell. A double swinging stop located on the bed of the machine locates the grooving tool and also the waving tool. When the waving tool is located, the tool carriage is automatically reciprocated. The re-

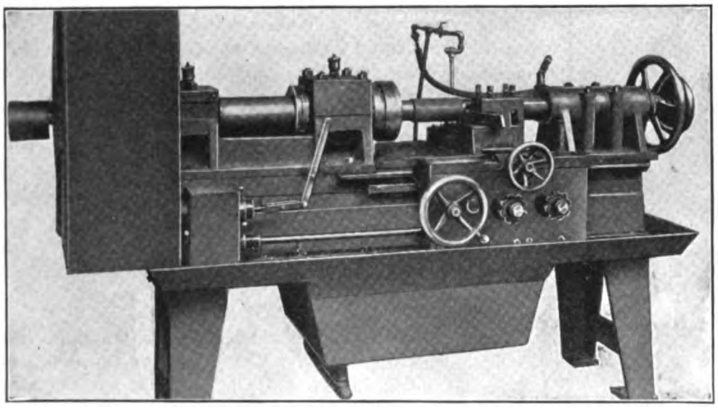


FIG. 1. SHELL-ROUGHING LATHE

Swing over bed, 16 in.; swing over tool-post slide, 7 in.; distance between centers, 24 in.; driving pulley, $19 \times 5\frac{1}{4}$ in.; floor space, 41x84 in.; weight, 3,200 lb.

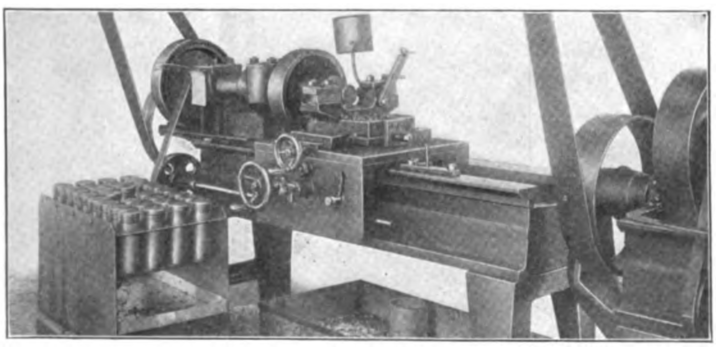

FIG. 2. GROOVING LATHE

Swing over bed, 20 in.; swing over tool-post slide, $4\frac{1}{2}$ in.; cutting tool, 10 in. over bed; distance from spindle to extreme travel of carriage, 17 in.; distance between ways, 8 in.; width of bed, 16 in.; driving pulley, $20 \times 5\frac{1}{4}$ in.; hole in spindle, $1\frac{3}{4}$ in.; floor space, 2 ft. 6 in. by 7 ft. 4 in.; weight, 3,200 lb.

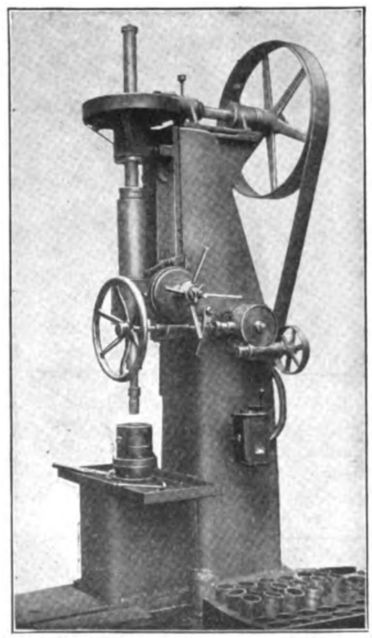

FIG. 3. SINGLE-SPINDLE DRILLING MACHINE

Distance from table to end of spindle, when up, 30 in.; travel of spindle, 20 in.; power feed per revolution of spindle, 0.012 in.; large diameter, $3\frac{11}{16}$ in.; small diameter, $3\frac{1}{4}$ in.; diameter of sleeve, 7 in.; driving pulley, $31 \times 6\frac{1}{4}$ in.; pulley speed, 170 r.p.m.; height overall with spindle up, 11 ft. 8 in.; floor space, 28x50 in.; approximate weight, 6,200 lb.

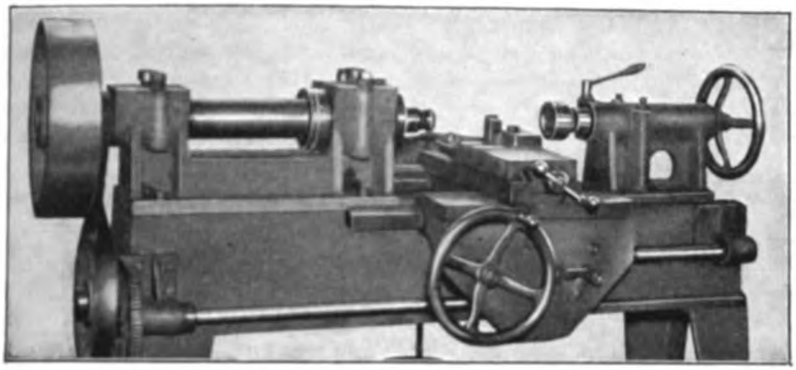

FIG. 4 SHELL-FINISHING LATHE

Swing, 18 in.; width of ways on bed, 17 in.; height from floor to center of spindle, 44 in.; driving pulley, 20x5⅝ in.; floor space, 3 ft. 4 in. by 6 ft. 8 in.; approximate weight, 3,000 lb.

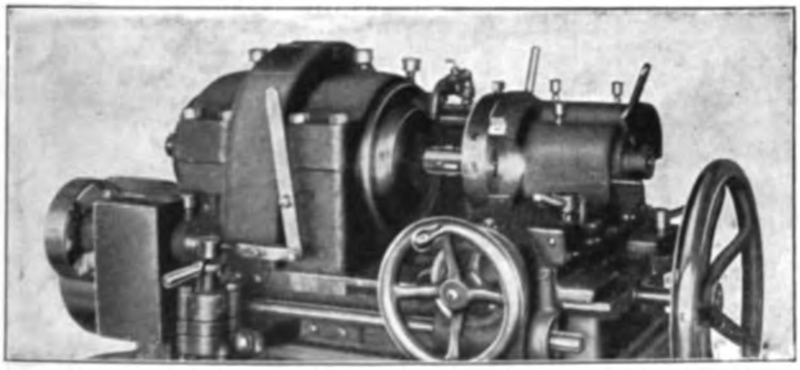

FIG. 5 SHELL-NOSING LATHE FOR 3.3-IN. SHRAPNEL

Swing, 14½ in.; width of ways, 17⅝ in.; height without legs, 2 ft. 5 in.; driving pulley, 14x3⅝ in.; spindle, 5½ in. in diameter by 19⅝ in. long; floor space, 2 ft. 9 in. by 5 ft.

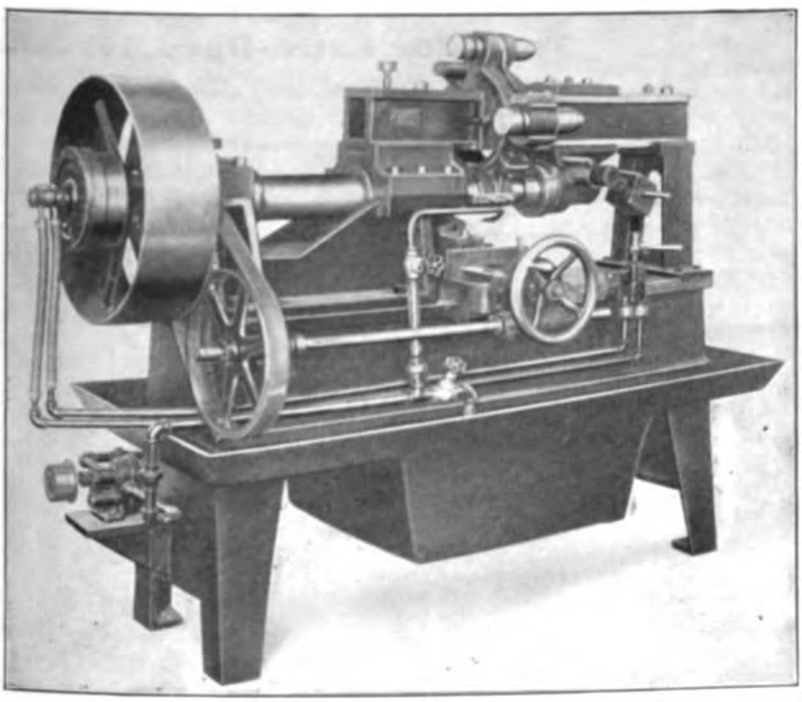

FIG. 6 COPPER-BAND TURNING LATHE

Distance between ways, 16 in.; driving pulley, 24x7⅛ in.; height from floor to center line of spindle, 44 in.; large diameter of spindle, [illegible] in.; small diameter of spindle, 4 in.; diameter of front spindle bearing, [illegible]; diameter of rear spindle bearing, 4 in.; height overall, 61 in.; floor space, 2 ft. 5 in. by 7 ft. 6 in.; weight, 3,[illegible]50 lb.

ciprocating motion for waving is accomplished by a hardened tool-steel roller contacting by spring pressure on a chilled cast-iron wave ring. The machine may be equipped with either air-operated or mechanically operated chucks.

The single-spindle drilling machine, Fig. 3, is designed to be sufficiently rigid to maintain alignment. The column is of one-piece construction. The machine is equipped for hand and power feed. The power feed is of the friction type and quickly engaged and released. An automatic feed trip is also used for releasing the feed. For hand feeding, a large handwheel is provided.

The lathe shown in Fig. 4 is intended for finish-turning the nose and diameter. A heavy pulley on the end of the spindle acts as a flywheel and aids in eliminating tool chatter. The nose end of the shell is screwed to a hardened tool-steel threaded plug located in the end of the spindle. The base end of the shell is centered and held in a self-centering center of special design. Micrometer-screw adjustment facilitates setting the tool for diameter. The machine is equipped for hand and power feed.

A turret forms part of the cross-slide on the nosing lathe, Fig. 5. The turret indexes in three positions. When indexed in the first position the nose end of the shell is bored and faced; in the second position the inside radius is formed; in the third position the shell is tapped. The machine is equipped for hand and power feed. Large, heavy handwheels are furnished for hand feeding. Three feeds are provided for power feeding. The feed screw for longitudinal feed is located in the center of the carriage.

In the copper-band turning machine, Fig. 6, the shell is held on the base end in a double-acting air chuck provided with hardened tool-steel jaws. The chuck fits into a large high-carbon steel spindle running in babbitted bearings. The nose end of the shell is held in a centering device which is made of hardened and ground tool steel running in a large bronze-bushed bearing, tapered so as to take up for wear. The turning tool bottoms solidly in the tool holder, which has three adjustments—one for the approximate height of the tool, one micrometer adjustment for the exact height and a side adjuster.

The machine is equipped with an automatic indexing magazine holding four shells. The feed is thrown out automatically by an adjusting feed tr[illegible]

Crank-Driven Slotter and New Speed Gear Box

The special feature of the crank slotter shown in Fig. 1 is the swiveling cutter bar guide, which adjusts 5 deg. each side of the perpendicular. This swivel adjustment is designed to make the machine especially adapted to die shaping. When furnished for toolroom work or duplication of parts, positive turret duplicating stops are added to the cross and lateral table motions.

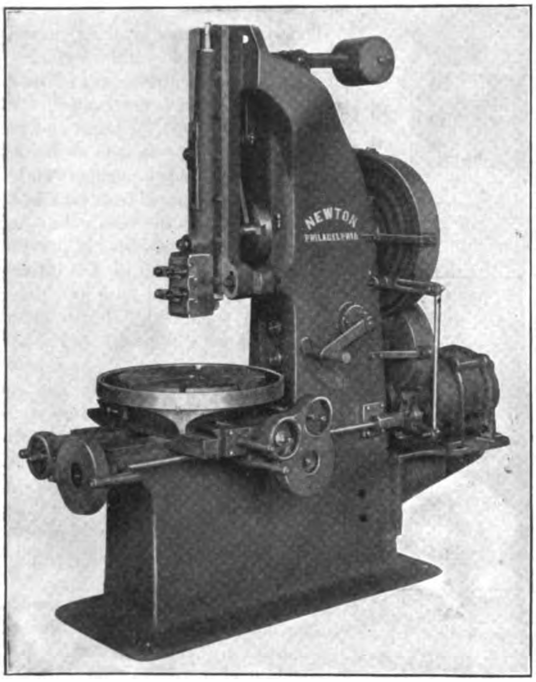

FIG. 1. CRANK-DRIVEN SLOTTER

The machine is driven by a 5-hp. 750-r.p.m. 50-cycle 3-phase 190-volt motor. To permit the use of a constant-speed motor on this machine and a number of its other types of machine tools the builders, Newton Machine-Tool Works, Philadelphia, Penn., have developed the oil-tight speed-change gear box shown in Fig. 2. This box is fitted with all steel or bronze gears, mounted on a sliding sleeve and controlled by latch levers fitted through the covers. The speed box is mounted within the upright.

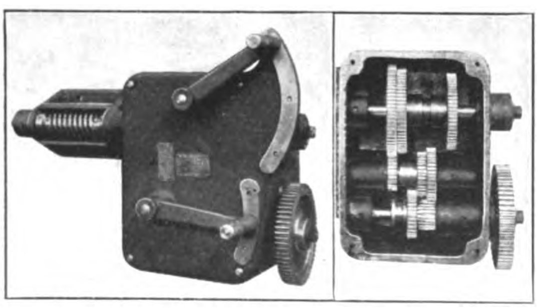

FIG. 2. OIL-TIGHT SPEED GEAR BOX

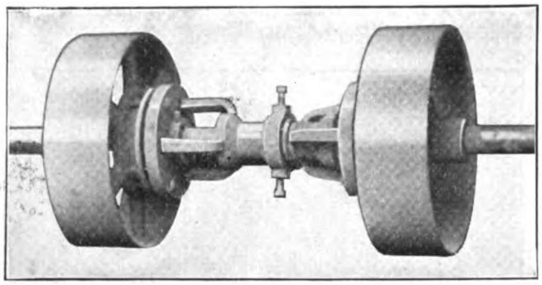
In order to dispense with belt shifting on belt-driven machines the speed box has been arranged to permit, when desired, the mounting of a single-step driving pulley on the opposite end of the shaft to that occupied by the driving gear as used on motor drives.

Pulley-Type Clutch

In the disk pulley-type clutch shown the wear is taken up by suitable lining which may be readily and economically renewed.

The clutch is so arranged that when released the clearance is sufficient to afford a clean release without drag. A large frictional surface is also provided. The engagement is gradual and the release instantaneous.

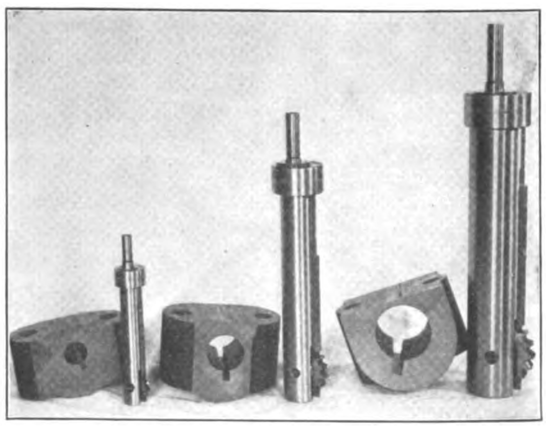


PULLEY-TYPE CLUTCH

The clutch pulley is supplied singly when the reverse is not used and is designed to be particularly adapted for machine-tool application. It is a recent product of the Porter Machine Co., Wooster, Ohio.

Tools for Extra-Deep Keyseats

While the tools shown closely resemble those previously made by the National Machine Tool Co., Cincinnati, Ohio, some changes were necessary in order to make them cut the extraordinary depth of keyseats required. As the figures will show, these keyseats are $1\frac{1}{2}$ times their width



TOOLS FOR EXTRA-DEEP KEYSEATS

Smallest size shown, $\frac{13}{16}$ in. in diameter, to cut keyseat $\frac{3}{16}$ in. wide by $\frac{9}{32}$ in. deep. Next size, $1\frac{5}{16}$ in. in diameter to cut $\frac{1}{4}$ in. wide by $\frac{3}{8}$ in. deep. Largest size, 2 in. in diameter, to cut $\frac{3}{8}$ in. wide by $\frac{9}{16}$ in. deep.

and would be difficult to cut in any other way and still obtain a slot true with the bore. These tools are intended for use in a drilling machine. The milling cutters are of high-speed steel, and the keyseats are finished at one cut.

Slip-Ring Induction Motors

A line of slip-ring induction motors, designed especially for heavy work, has been recently developed by the Westinghouse Electric and Manufacturing Co., Pittsburgh, Penn. The motors are furnished in sizes from 1½ to 200 hp. The frames of the smaller sizes are made up of steel laminations riveted between forged-steel end shields; in the larger sizes the frames are made of rolled steel.

PERSONALS

H. T. White, for a number of years tool superintendent of the Modern Tool Company, Erie, Penn., now represents the company in the Detroit territory.

D. M. Crossman has been appointed publicity manager of the Niles-Bement-Pond Co., succeeding H. M. Cleaver, who was recently transferred to the Plainfield works. Mr. Crossman was formerly assistant manager of publicity.

OBITUARY

Oliver B. Niedringhaus, superintendent of the National Enameling and Stamping Co., Granite City, Ill., died at his home in St. Louis, Mo., on May 2[illegible], after a long illness.

Fred Arnold Welles, inventor of the friction adjustment for calipers, died in Milwaukee, Wis., May 14. Mr. Welles was born in Milwaukee, June 9, 1863. After attending the public schools he entered the employ of the Edward P. Allis Reliance Works, where he learned the machinist's trade. From early youth he had shown great aptitude for things mechanical, and many steam engines, boilers and other machines were built in his father's gun shop. In this work as a boy and later as an apprentice, considerable experience was gained and he invented a cut-off and governor which bid fair to become a disturbing element in steam engineering. He also invented an adjustment for calipers and a type of surface gage having features not found on any others then made. In all he developed about one hundred different patentable tools, but never patented them owing to the continual barrier of ill health. After serving his apprenticeship he vacillated between the cut-off scheme and his tools and chose the latter, as the former seemed to him too gigantic a scheme to launch for his poor health, although it had proved very satisfactory experimentally. So he placed the Welles caliper on the market in 1889. In 1894 he became greatly interested in the gas engine and a number of different types of engines were built. He was among the first to enter the automobile field, and built a car having numerous original features, such as the planetary gear and cantilever spring as now used, the car in general being modeled after that of Leon Bollee, France. In 1905 he moved to Waukesha, Wis., where he also moved his tool business. Continual ill health forced him to dispose of this business to one of his friends and former employees.

BUSINESS ITEMS

Van Dorn & Dutton Co., Cleveland, Ohio, has removed its Denver, Colo., offices from the Ideal Building to 1633 Tremont St. C. H. Davidson, district sales manager.

To more adequately take care of its growing business in New England the Hoskins Manufacturing Company has opened a branch office in the Equity Bldg., Boston, Mass., of which J. E. Hines will be in charge.

The Modern Tool Company, Erie, Penn., have decided to devote their manufacturing facilities exclusively to their line of self-contained internal, plain and universal grinders, in pursuance of which policy they have disposed of their overhead countershaft line of grinders to Albert J. Ott, Chicago, Ill.

FORTHCOMING MEETINGS

Master Car Builders' Association. Annual meeting, June 14-17, Atlantic City, N. J. Joseph W. Taylor, secretary, Karpen Building, Chicago, Ill.

American Railway Master Mechanics' Association. Annual meeting, June 17-21, Atlantic City, N. J. Joseph W. Taylor, secretary, Karpen Building, Chicago, Ill.

American Society for Testing Materials. Annual meeting June 27 to July 1, 1916, Hotel Traymore, Atlantic City, N. J. Edgar Marburg, secretary, University of Pennsylvania, Philadelphia, Penn.

American Society of Mechanical Engineers. Monthly meeting first Tuesday. Calvin W. Rice, secretary, 29 West Thirty-ninth St., New York City.

Boston Branch National Metal Trades Association. Monthly meeting on first Wednesday of each month, Young's Hotel. W. W. Poole, secretary, 40 Central St., Boston, Mass.

Providence Association of Mechanical Engineers. Monthly meeting fourth Wednesday each month. J. A. Brooks, secretary, Brown University, Providence, R. I.

New England Foundrymen's Association. Regular meeting second Wednesday of each month. Exchange Club, Boston, Mass. Fred F. Stockwell, 205 Broadway, Cambridgeport, Mass.

Engineers' Society of Western Pennsylvania. Monthly meeting third Tuesday; section meeting, first Tuesday. Elmer K. Hiles, secretary, Oliver Building, Pittsburgh, Penn.

Rochester Society of Technical Draftsmen. Monthly meeting, first Thursday. O. L. Angevine, Jr., secretary, 857 Genesee St., Rochester, N. Y.

Superintendents' and Foremen's Club of Cleveland. Monthly meeting third Saturday. Philip Frankel, secretary, 310 New England Building, Cleveland, Ohio.

Western Society of Engineers, Chicago, Ill. Regular meeting first Wednesday evening of each month, excepting July and August. J. H. Warder, secretary, 1735 Monadnock Block, Chicago, Ill.

Philadelphia Foundrymen's Association. Meetings first Wednesday of each month. Manufacturers' Club, Philadelphia, Penn. Howard Evans, secretary, Pier 45 North, Philadelphia, Penn.

Technical League of America. Regular meeting second Friday of each month. Oscar S. Teale, secretary, 35 Broadway, New York, N. Y.

Prices--Materials and Supplies

IRON AND STEEL

Pig Iron—Quotations were current as follows at the points and dates indicated:

	June 1, 1916	One Month Ago	One Year Ago
No. 2 Southern Foundry, Birmingham	$15.00	$15.00	$9.50

The contract has been awarded for the construction of a 4-story addition to the plant of the Ajax Metal Co., Frankford Ave. and Richmond St., Philadelphia, Penn. Noted Apr. 20 and 27.

The E. P. Alexander Co., manufacturer of machinery, Philadelphia, Penn., has awarded the contract for several additions to its plant. Estimated cost, $54,000.

John W. De Long, Delmar Apts., Philadelphia, Penn., has awarded the contract for the construction of a 2-story garage at Chelton and Paulaski Ave. Estimated cost, $20,000.

The Leeds & Northrup Co., 4901 Stenton Ave., Philadelphia, Penn., is having plans prepared by Morris & Erskine, Arch., 1420 Chestnut St., Philadelphia, for a 4-story, 50x100-ft. factory for the manufacture of electrical instruments.

The Midvale Steel and Ordnance Co., Philadelphia, Penn., is in the market for a large number of cranes.

The Pennsylvania R.R., Philadelphia, Penn., is in the market for several cranes. A. C. Shand, Philadelphia, Ch. Engr.

Bids are being received by F. A. Rianhard, Arch., Masonic Bldg., Williamsport, Penn., for a 1-story assembling plant for the Lyvoming Foundry and Machine Co., Williamsport. Estimated cost, $20,000.

The Standard Car Manufacturing Co., Youngstown, Ohio, has awarded the contract for the construction of a steel-car plant near Sharon, Penn. Estimated cost, $300,000. C. H. Modd, 1512 Florencedale Ave., Youngstown, Ohio, Mgr.

The Baltimore Car and Foundry Co., Baltimore, Md., a branch of the Standard Steel Car Co., Pittsburgh Penn., is constructing a 40x90x780-ft. machine shop.

According to press reports the Baltimore & Ohio Railroad Co., Baltimore, Md., contemplates enlarging its shops at Cumberland, Md. F. L. Stuart, Baltimore, Ch. Engr.

SOUTHERN STATES

The International Steel and Plate Co., Munsey Trust Bldg., Washington, D. C., plans to construct a shipbuilding plant at Quantico, Va. About $30,000 worth of equipment will be required. H. M. Isaac, Secy.

The Wheeling Steel and Iron Co., Wheeling, W. Va., plans to construct additional mills at its plant at Yorkville, W. Va. (Glenhayes post office).

The Sloss-Sheffield Steel and Iron Co., Birmingham, Ala., plans to construct a byproduct plant at North Birmingham.

J. H. Talent, Dayton, Tenn., is in the market for machinery for the manufacture of plow handles.

The Ashland Iron and Mining Co., Ashland, Ky., plans to construct a new finishing mill.

MIDDLE WEST

The contract has been awarded for the construction of a factory at Canal Dover, Ohio, for the Penn Iron and Steel Co. Estimated cost, $25,000.

Bids will soon be received for the construction of a 1-story, 80x440-ft. factory for the J. G. Brill Car Co. at Cleveland, Ohio. S. M. Curven, Pres.

Bids are being received by F. Baird, Arch., 505 Bangor Bldg., Cleveland, Ohio, for the construction of a 1-story, 47x100-ft. garage for the County Club at Cleveland. Estimated cost, $12,000.

The contract has been awarded for the construction of a 1-story addition to the plant of the A. R. Davis Motor Co., at 2020 Euclid Ave., Cleveland, Ohio. Estimated cost, $20,000. Noted May 25.

We have been advised that the Northern Blower Co., 4515 Storer Ave., Cleveland, Ohio, is in the market for heavy power sheet metal working machinery. Noted May 11 and 25.

The contract has been awarded for the construction of a factory at Cleveland, Ohio, for Wilson S. Yerger, metal manufacturer, 1226 Howard St., Philadelphia, Penn. Estimated cost, $4,000.

The American Locomotive Co. plans to construct a plant at Elyria, Ohio. Estimated cost, $65,000. Harry Weil, Gen. Mgr.

Bids have been received for the construction of a foundry at Lorain, Ohio, for the American Shipbuilding Co. Estimated cost, $50,000. A. G. Smith is Gen. Mgr. Noted Apr. 6 and 20.

The Blackwood Steel Castings Co. is constructing a steel foundry at Springfield, Ohio. Noted May 18.

Bids are being received for the construction of a 1-story, 50x160-ft. garage at Toledo, Ohio, for W. T. Hubbard, 384 South Erie St., Toledo.

The contract has been awarded for the construction of a factory at Youngstown, Ohio, for the General Fireproofing Co., manufacturer of steel products. W. H. Foster, Pres. and Gen. Mgr.

The contract has been awarded for the construction of an addition to the factory of the Columbus Handle and Tool Co., at Columbus, Ind.

The contract has been awarded for the construction of an addition to the plant of the Maxwell Newcastle Manufacturing Co., manufacturer of automobile parts, at Newcastle, Ind. Noted May 4.

The Hoover Steel Ball Co. plans to construct a 40x400-ft. addition to its plant at Ann Arbor, Mich., by its engineering forces. L. J. Hoover, Vice-Pres. and Gen. Mgr.

The H. B. Sherman Manufacturing Co., manufacturer of brass goods, is constructing an addition to its plant at Barney and Kalamazoo St., Battle Creek, Mich.

The Roeller Foundry Co. plans to construct a plant at North Water and Trumbull St., Bay City, Mich.

The Celfor Tool Co. plans to construct an addition to its plant at Buchanan, Mich.

The Gold Valve Engine Co., Charlotte, Mich., recently incorporated with $40,000 capital stock, will construct a plant at Charlotte for the manufacture of gasoline engines. George M. Fenn is Pres.

Bids are being received by Harry S. Angell, Arch., 722 Free Press Bldg., Detroit, Mich., for the construction of a 2-story factory at Detroit for the Detroit Brass Works. Gordon C. Hall, 1322 Brooklyn Ave., Secy.

Plans are being prepared for a plant on West Fort St., Detroit, Mich., for the Detroit Seamless Steel Tube Co. Noted May 11.

Siewek Bros., manufacturer of tools, jigs and dies, has awarded the contract for the construction of an addition to its plant at 75 Baltimore Ave., Detroit, Mich.

Plans have been prepared for the construction of a 2-story, 95x150-ft. factory at Detroit, Mich., for the Wadsworth Manufacturing Co., manufacturer of automobile bodies. W. C. Rowling, 1256 East Jefferson Ave., Secy. Estimated cost, $40,000.

The contract has been awarded for the construction of a garage at Flint, Mich., for B. J. McDonald. Estimated cost, $30,000.

The contract has been awarded for the construction of a factory at Hamtramck, Mich., for the Hygeia Filter Co. Noted May 25.

The contract has been awarded for the construction of an addition to the plant of the Spenser-Smith Machine Co. at Howell, Mich.

Bids have been received for the construction of an addition to the factory of Werner & Pfleiderer Co., manufacturer of special machinery, at Saginaw, Mich.

The Michigan Crowned Fender Co. is constructing a factory at Ypsilanti, Mich.

The U. S. Pressed Steel Co. is constructing a plant at Ypsilanti, Mich.

Bids are being received for the construction of a 1-story, 100x160-ft. factory at Aurora, Ill., for the Lyon Metallic Manufacturing Co., manufacturer of metal lockers. Estimated cost, $15,000.

We have been advised that the Apex Appliance Co., manufacturer of washing machines, 3.21 West 5th St., Chicago, Ill., is in the market for lathes, drill presses and electric elevator. Noted May 18.

The Appleton Electric Co., manufacturer of electrical specialties, 224 North Jefferson St., Chicago, Ill., has purchased a site at Paulina and Wellington St. on the Chicago River, Chicago, on which it plans to construct a new plant.

N. Dinghey, 30 North Dearborn St., Chicago, Ill., will construct a garage at 7025 South Halsted St., Chicago.

The Jones Foundry and Machine Co., North Ave. and Noble St., Chicago, Ill., will construct a foundry and machine shop at 1200 South Kostner Ave., Chicago. Estimated cost, $[illegible],000.

The Ogren Motor Works is constructing a 3-story, mill construction building on Sacramento Blvd. between Chicago and Grand Ave., Chicago, Ill. Estimated cost, $85,000.

The contract has been awarded for the construction of a 2-story garage at 3720 Southport Ave., Chicago, Ill., for Matthew Schmidt. Estimated cost, $10,000. Noted May 18.

An addition is being built to the foundry of the Vermillion Malleable Iron Co., Hoopeston, Ill.

The contract has been awarded for the construction of a plant at Peoria, Ill., for the Keystone Steel and Wire Co. Estimated cost, $1,750,000. Noted May 4 and 25.

The contract has been awarded for the construction of a 1- and 2-story, 50x200-ft. foundry for the Malleable Iron Range Co., Beaver Dam, Wis. A. G. Hill is Pres.

The main building of the Hess Iron Works, Green Bay, Wis., has been purchased by the Green Bay Drive Calk Co., Green Bay, who will equip it for a drop forge plant for the manufacture of horse shoes and calks for horse shoes.

The Thomas B. Jeffery Co., manufacturer of automobiles, has awarded the contract for the construction of a foundry and manufacturing building at Kenosha, Wis.

The Aluminum Goods Manufacturing Co. is constructing a 50x300-ft. addition to its plant at Manitowoc, Wis.

The contract has been awarded for the construction of a 1-story garage at Milwaukee, Wis., for the Milwaukee Building Construction Co. Estimated cost, $10,000.

Bids have been received for the construction of a 1-story, 50x120-ft. garage at Osceola, Wis., for E. A. Zorn.

The contract has been awarded for the construction of a factory for the Continental Truck Manufacturing Co. at Superior, Wis. Estimated cost, $50,000.

WEST OF THE MISSISSIPPI

Fire recently destroyed the factory of Woods Bros. Silo and Manufacturing Co., 36th and Orchard St., Lincoln, Neb. Loss, $100,000.

Plans are being prepared by W. V. Kernan, Bee Bldg., Omaha, Neb., for the construction of a 100x132-ft. garage for the Blackstone Holding Co., Bee Bldg. Estimated cost, $25,000.

Plans are being prepared by C. A. Randall, Arch., Sheridan, Wyo., for the construction of a garage at Buffalo, Wyo., for I. E. Gilbert, Sheridan.

The Barks & Barstow Manufacturing Co., Valley Park, Mo., manufacturer of steel roofing and specialties, will build a factory adjacent to the plant of the Wrought Iron Range Co., St. Louis, Mo.

The Maxwell Motor Co. plans to construct an assembling plant at Dallas, Tex.

Plans are being prepared and bids will soon be received by L. H. Ruggles, Arch., 330 Robinson Bldg., Tulsa, Okla., for the construction of a 100x140-ft. garage for H. C. Stahl and M. A. Younkman, 1217 South Baltimore St. Estimated cost, $15,000.

WESTERN STATES

The Wilcox Auto Co. plans to rebuild its garage and machine shop at Burley, Idaho, which was recently destroyed by fire.

Higgs Bros. plans to construct a 50x140-ft. garage and machine shop at 2nd and Main St., Mansfield, Wash.

Plans are being prepared by W. W. DeVeaux, Arch., for the construction of a 50x140-ft. garage and machine shop at 3rd and Yakima St., North Yakima, Wash. Estimated cost, $10,000.

D. A. Connolly will construct a garage at 34 Broadway, Portland, Ore.

CANADA

The Canada Cycle and Motor Co. will construct a plant at Weston, Que. Estimated cost, $100,000.

The Board of Control of Ottawa, Ont., plans to construct a civic garage and repair shop. Norman H. Lett, City Clk.

Press reports state that the Rumely Tractor Co. plans to construct a garage at Calgary, Alta. Estimated cost, $30,000.

GENERAL MANUFACTURING

NEW ENGLAND STATES

The Cushman-Hollis Co., Auburn, Maine, manufacturer of shoes, will construct a 4-story, 143x164-ft. addition to its plant at Union and Court St.

Press reports state that the Savage Paper Co., Skowhegan, Maine, plans to reconstruct its paper mill.

The Costikyan Carpet Co., recently incorporated, plans to construct a plant at Lowell, Mass. M. W. Costikyan, Pres.

The West End Thread Co. has awarded the contract for the construction of a 3-story addition to its plant at Millbury, Mass.

The United Lace and Braid Co. will build an addition to its plant on Wellington Ave., Auburn, R. I. (Providence post office). Estimated cost, $50,000.

The Simons Braid Co., Dexter St., Providence, R. I., plans to construct a 2-story, 70x120-ft. addition to its plant at Providence.

Plans are being prepared for the construction of an 83x163-ft. mill building at Thomesville, Conn., for the Winchester Woolen Co. Estimated cost, $50,00. Noted Apr. 20.

MIDDLE ATLANTIC STATES

The contract has been awarded for the construction of a factory at Albany, N. Y., for B. & W. Bernstein, 96 South Pearl St., manufacturer of carpets. Estimated cost, $10,000.

Bids are being received by Benjamin Driesler, Arch., 153 Remsen St., New York, N. Y. (Borough of Brooklyn), for 3-story building on Ditmas Ave. for William Beckers Aniline and Chemical Works, Brooklyn. Estimated cost, $20,000. Noted Mar. 30.

Plans have been prepared for a 2-story factory in Elizabeth St. between Lake Ave. and Genesee River, Rochester, N. Y., for Rochester Folding Box Co. Estimated cost, $175,000.

Plans have been prepared by J. G. Elendt, Engr., Cutler Bldg., Rochester, N. Y., for a 2-story chemical cold-storage building at Ransomville, N. Y., for G. E. Hubble. Estimated cost, $75,000.

The Coats Manufacturing Co., Wellsville, N. Y., manufacturer of furniture, is building 2 additions to its plant.

The New Jersey Leather Co., Camden, N. J., has awarded the contract for the construction of a 2-story brick factory. Estimated cost, $55,000.

The Hopewell Valley Canning Co., Hopewell, N. J., will improve its plant and install new machinery.

The American Mono Service Co., Newark, N. J., manufacturer of paper containers, will enlarge and improve its plant on Verona Ave.

The Strong Rubber and Asbestos Co., Newark, N. J., will improve and enlarge its plant on Bigelow St.

H. Entin, Trenton, N. J., will build a factory on Commercial Ave. for the manufacture of burlap bags.

The Verona Chemical Co., Verona, N. J., will build a 2-story addition to its plant at Verona and Riverside Ave.

The Scott & Bowne Co., manufacturer of chemicals, has awarded the contract for the construction of a factory at Watsessing, N. J. (Bloomfield post office).

The Union Powder Co., 42 Broadway, New York, N. Y., plans to construct an addition to its plant at Emporium, Penn., to be used for the manufacture of nitric and sulphuric acid.

The Harbred Silk Co., Galeton, Penn., is constructing a silk mill.

J. S. Ward & Co., manufacturer of chemicals, care of Ward C. Haffner, Railroad St., Hanover, Penn., has awarded the contract for the construction of a 2-story addition to its plant. Estimated cost, $10,000.

The contract has been awarded for the construction of a 2-story addition to the plant of Charles P. Cochrane, Butler and N St., Philadelphia, Penn., manufacturer of carpet. Estimated cost, $16,500. Noted May 25.

The Belmont Packing and Rubber Co., Philadelphia, Penn., is having plans prepared by Carl P. Berger, South Penn Sq. Bldg., Philadelphia, for a 2-story factory at Seviva and Butler St. Noted May 18.

Plans have been prepared by J. Martsolf, Arch., House Bldg., Pittsburgh, Penn., for the reconstruction of the plant of the Beaver Refrigerator Co., New Brighton, Penn., recently destroyed by fire. Estimated cost between $18,000 and $35,000. H. S. Hawthorne, New Brighton, Mgr. Noted May 11.

The contract has been awarded for the construction of a 3-story optical factory on South 8th St., Reading, Penn., for the Pennsylvania Optical Co., Reading. Noted Dec. 16 and Apr. 20.

Bids are being received by I. C. Eberly, Oakbrook, Reading, Penn., for a 1-story factory to be leased by the Oakbrook Hosiery Co., Oakbrook.

SOUTHERN STATES

The E. I. du Pont de Nemours Powder Co., Wilmington, Del., plans to construct a dynamite plant at Williamsburg, Va.

The Paden City Glass Co., Paden City, W. Va., recently organized, plans to construct a factory at Paden City.

The Malines Knitting Mills, Winston Salem, N. C., will build an addition to its plant. Estimated cost, $4,000.

The Melrose Knitting Mills, Raleigh, N. C., plans to install new machinery in its plant.

The Asceptic Cotton Co. is building a new plant at Alton Park, Tenn.

The Kalbfleich Chemical Corporation, Chattanooga, Tenn., plans to construct a $75,000 plant at Chattanooga.

The Thatcher Spinning Mills, Chattanooga, Tenn., is building a 150x500-ft. plant. Noted Dec. 30.

The Kelly Handle Co., Memphis, Tenn., plans to establish a handle factory at New South Memphis. Estimated cost, $100,000. S. J. Weigel, Central Bank Bldg., Memphis, Arch.

The Memphis Furniture Manufacturing Co., Memphis, Tenn., will build a 2-story addition to its plant.

W. E. Goertz, 520 Stahlman Bldg., Nashville, Tenn., is in the market for machinery for the manufacture of pearl buttons.

The American Metallic Packing Co., Lexington, Ky., is in the market for a 10-ton locomotive crane, equipped for bucket, a 5- or 6-ton tamden steam road roller and a 10x10x10 steam air compressor, all second hand.

MIDDLE WEST

The B. F. Goodrich Co., manufacturer of rubber goods, has awarded the contract for the construction of a factory at Akron, Ohio. Estimated cost, $25,000.

The Pearce Tire and Rubber Co. is constructing a plant at Ashtabula, Ohio.

The American Puncture-Proof Tire Co. has purchased a site on Harvard Ave., Cleveland, Ohio, and will construct a factory. Estimated cost, $50,000.

The Forest City Engineering Co., Engr., 512 Hippodrome Bldg., Cleveland, Ohio, will soon award the contract for the construction of a factory at Cleveland, for the National Artificial Silk Co., 735 Central Ave. Estimated cost, $300,000. Noted May 18 and 25.

The McCoy-Nelson Sanitary and Stoneware Co. will construct a 2-story, 10x100-ft. addition to its plant at Roseville, Ohio.

Plans are being prepared by H. L. Bass & Co., 801 Hume Mansur Bldg., Indianapolis, Ind., for 1-story, 280x300-ft. factory for Western Cabinet Co., Indianapolis, Ind. Estimated cost, $40,000. O. K. Mahorney, Claypool Hotel, Indianapolis, is interested.

The contract has been awarded for the construction of an addition to the packing plant of the Sullivan Packing Co. at Beecher Ave. and Michigan Central R.R., Detroit, Mich. Estimated cost, $75,000.

The Welch Furniture Co. will construct a factory at Grand Rapids, Mich.

The August Carlson's Glove Manufacturing Co. contemplates enlarging its factory at Marquette, Mich. Estimated cost, $5,500.

The Kompass & Stoll Co., manufacturer of kitchen cabinets, is constructing a 2-story, 75x75-ft. addition to its factory at Niles, Mich.

The Monroe Body Co., manufacturer of carriages, etc., is constructing an addition to its factory at Pontiac, Mich. Noted May 11.

The Chicago Rawhide Co. has awarded the contract for the construction of a 1-story tannery at 1301 Elston Ave., Chicago, Ill. Estimated cost, $6,000.

WEST OF THE MISSISSIPPI

Fire recently destroyed the plant of the Montana Sash and Door Co., Billings, Mont. Loss, $150,000.

The Farmers Union, Swifton, Ark., plans to construct a cotton gin at Newport, Ark. Estimated cost, $12,000.

The Deport Oil Mill, Deport, Tex., will construct a cotton seed oil mill. Estimated cost, $35,000.

The Mexico Guayule Co. will construct a factory at El Paso, Tex., for extracting rubber from the wild guayule shrub. Estimated cost, $50,000.

The Loudon Hosiery Mills, Loudon, Tex., will construct a 3-story addition to its plant.

WESTERN STATES

The Crown-Willamette Paper Co. will enlarge its plant at Oregon City, Ore. Louis Bloch, Vice-Pres.

The Fall Brook Citrus Association plans to construct a packing plant at Fall Brook, Calif.

The contract has been awarded for the construction of a plant on Santa Fé Ave., Los Angeles, Calif., for the manufacture of boxes for the Southern California Box Co., 1335 East 6th St. Noted Feb. 17.

A. B. Shoemaker plans to construct a fruit packing plant at Modesto, Calif. Estimated cost, $6,000.

The John Horstmann Chemical Co. plans to construct a factory at Redwood City, Calif. Estimated cost, $25,000.

CANADA

S. W. Halliday, 20 Arlington Ave., Montreal, Que., will construct a factory on Catharine St., Montreal, for the manufacture of carriages. Estimated cost, $6,000.

Winstainer & Son, 58 St. Lawrence Blvd., Montreal, Que., manufacturer of picture frames, will rebuild its factory at Montreal which was recently destroyed by fire and will install new machinery.

The Ardiel Shoe Co. contemplates constructing an addition to its plant at Elmira, Ont. Estimated cost, $6,000.

The Solid Leather Co. has awarded the contract for the construction of an addition to its plant at Preston, Ont. Estimated cost, $50,000. Noted May 25.

The Canadian Consolidated Rubber Co. is constructing an addition to its plant at St. Catherines, Ont. Estimated cost, $25,000.

Talks With Our Readers

By the Publisher

I PICKED up a copy of the June 1st issue and as I read the advertisements the thought occurred to me that you are certainly being benefitted greatly by modern advertising—

The kind of advertising that only good products can stand.

It was surprising to me to see how many concerns put their business propositions in terms that made it absolutely impossible for you to secure other than completely satisfactory results.

One concern put it in black and white that if the article is not satisfactory it "can be returned at our expense." Another has confidence enough in its product to sell it to you "on any terms of guarantee that you may desire." Still another says: "If it doesn't live up to every claim you don't have to pay for it."

With advertisers standing back of their product in this way—is it any wonder that I call the Buying Section the "Buyers Friend?"

Is it any wonder that the progressive machine shop man uses this section as a real "Buying Guide?"

Are you making it count BIG for you?

Flue-Reclaiming System of the Santa Fe Shops

By Ethan Viall

SYNOPSIS—Heretofore a large number of flues have been scrapped because there has been no practical way to repair flaws or thin spots more than 1 or 2 ft. from the ends. By the method described, thin places may be cut out anywhere in the length of the flue and successfully repaired. All repairs are of course rigidly tested to insure results.

One of the great and continual expenses of any railroad is the constant repair or replacing of locomotive-boiler flues. Safe-ending is almost a continuous

FIG. 1. RATTLER HOUSE, SHOWING PISTON CYLINDER

FIG. 2. VIEW OF OPPOSITE END

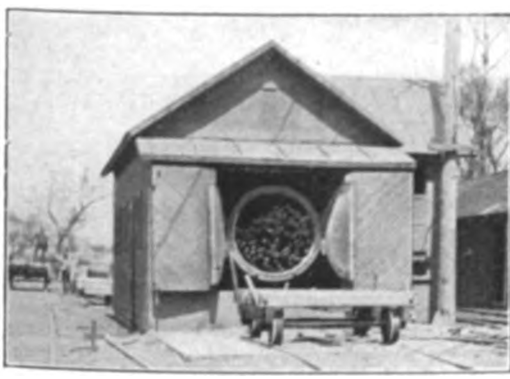

FIG. 3. RATTLER READY TO DISCHARGE LOAD

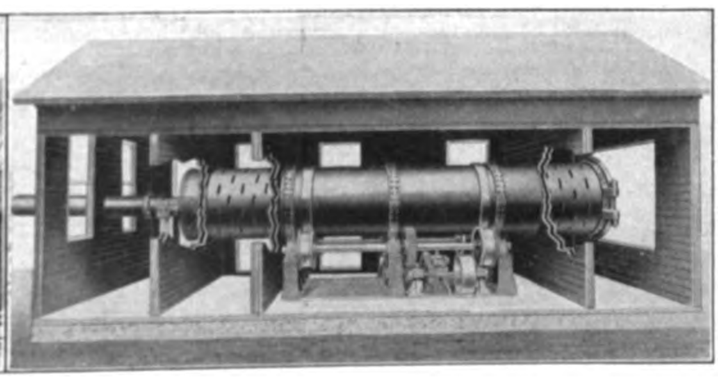

FIG. 4. VIEW SHOWING SOME OF THE DETAILS

performance, but the ordinary safe-end welder will not weld on pieces over 35 or 40 in. long, and 18-in. lengths are about the practical limit. In consequence a 20 ft. flue might have a thin spot of only an inch or so in the middle, and yet two pieces nearly 10 ft. long would have to be scrapped because there has been no good way of eliminating the thin spot. If the defect is merely a pit or small place, sometimes oxyacetylene is successfully employed, but for larger places this method is impractical for numerous reasons. After long and careful study of the problem the mechanical department of the Santa Fe Ry. finally evolved a way to reclaim a large proportion of the otherwise scrap flues. An outfit was installed in the Topeka shops of the system, and after a period of more or less expensive experimenting it has been in successful operation for about eight months. Although some of the steps described in this article are familiar to every railroad-shop man, the process of handling the flues will be shown from start to finish, with the exception of the removal and replacement in the boilers.

As in all railroad shops, the first operation after removal from the boilers is to rattle the flues to remove scale of all kinds and thoroughly clean them, both inside and out. Two methods of rattling are in general use—the wet and dry process. In the Topeka shops the dry process only is employed; and as the rattler itself has some unique features, it will be described in detail. It was made by the Baird Pneumatic Tool Co., Topeka, Kan., and several are in use along the system. The rattler at the Topeka shops is in a separate building, as shown in Fig. 1. Projecting out from this building is a long tube, which is the piston cylinder. The piston is used to shove out the rattled flues or to alter the length of the rattling chamber. A view from the opposite end, with the building doors thrown open, is given in Fig. 2. In Fig. 3 the end of the rattler is shown open ready for the flues to be pushed out onto the waiting truck. A wash drawing of the device is shown in Fig. 4. The

machine is capable of handling a full set of boiler tubes at once, or from 250 to 300 tubes. It will thoroughly clean them inside and out in from 2 to 6 hr., according to the kind of scale deposited on the flue. The average in this shop is about 900 per day of 10 hr. Some scales can be rattled in an hour, while some with the hardest of lime require 6 hr. A movable head operated by means of the air piston referred to makes flues as it goes. The result is beautifully clean and bright flues that look like new.

The main part of the rattler is contained in a central room, which is practically dust proof. Here the motor and driving mechanism are placed. This prevents all unnecessary wear on the parts and is managed by having the body of the rattler ride in rings set in wooden partition walls, which effectually keep the dust out of

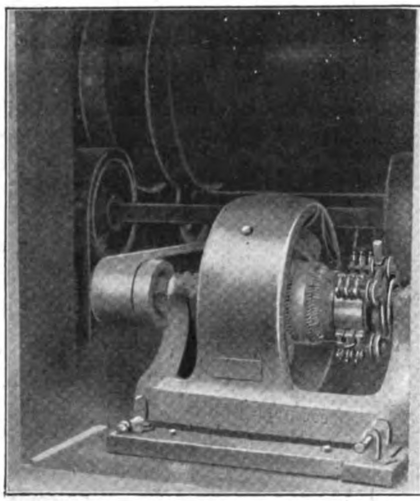

FIG. 5. METHOD OF DRIVING THE RATTLER

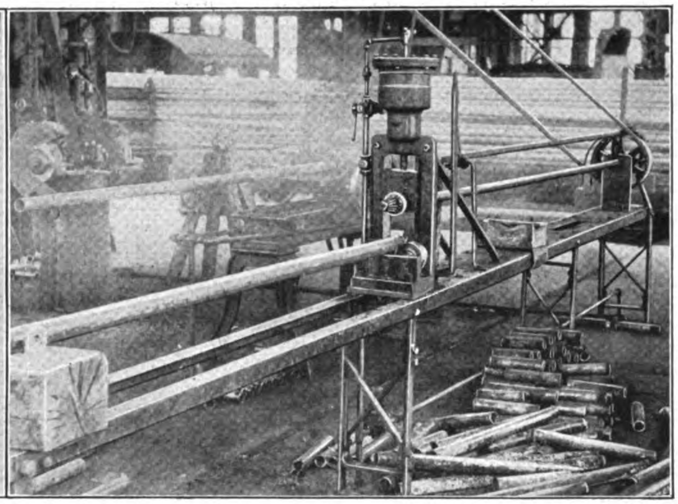

FIG. 6. THE EXTRA-LONG CUTOFF MACHINE

it possible to rattle flues 24 ft. in length or shorter and hold them so that they will not have sufficient lateral movement to tangle and be destroyed, as is often the case with a rattler in which no such provision is made. When 20-ft. flues are rattled, the head is adjusted to 20 ft. 6 in., which gives them only 6 in. of lateral movement while being cleaned. After the flues have the central part. The rattling chamber itself rides on flanged rollers operated through gearing at the back, which is belted to a drive motor in front, where it is easily accessible, as shown in Fig. 5.

After the flues have been rattled, they are carefully gone over by experienced men, who test them with hammers for flaws or thin spots. As soon as a weak

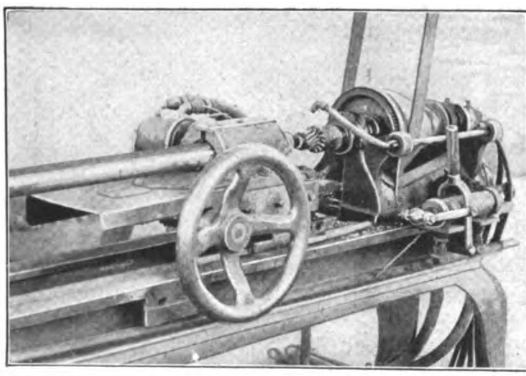

FIG. 7. THE END-REAMING AND SQUARING MACHINE

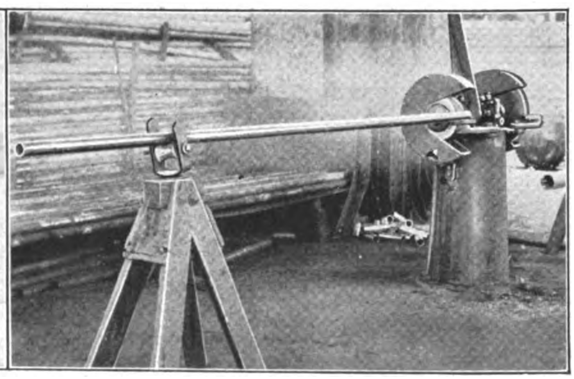

FIG. 8. METHOD OF BRIGHTENING THE ENDS

been rattled, the end doors are opened, air is let into the piston cylinder, and the whole lot is pushed out into the basket car, as previously mentioned. By referring to the drawing, it will be seen that the main body of the rattler has no opening in it for the escape of the lime, openings at the ends only being provided. This method holds the lime in for scouring purposes until it gradually works to the end dust chambers, scouring and grinding both inside and outside of the spot is detected, it is marked with chalk as far as it extends. As the tester finishes a flue, he places it in a cradle. When this is full, it is run to the cutoff machine, Fig. 6, which is air operated and differs but little from those in common use, except that it will cut to the middle of a 24-ft. flue if needed. The operator of this machine cuts out the weak places that the inspector has marked. Sometimes these are only a few inches in length; at other times they are several

feet long, as shown by the pieces on the floor under the machine. To pass as "good," a piece of any length must not only be free from thin places, but must weigh a certain amount per foot. As a rule, it is not necessary to weigh pieces, as an operator soon gets the "heft" of a piece as unerringly as a cashier detects counterfeits.

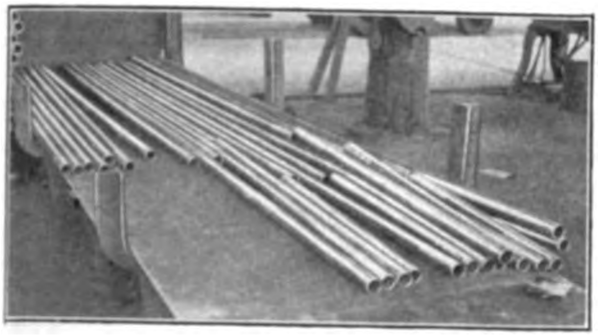

FIG. 9. METHOD OF SORTING OUT THE LENGTHS

As the various good pieces are to be butt-welded into full flue lengths, a clean, straight end is desirable. This is obtained by milling, as shown in Fig. 7. The flue to be milled is held in an air-operated set of jaws and fed to the revolving mill, which mills off the end square and also reams out the inside so as to remove the burr left by the cutoff.

In order to give the gripping jaws of the welder good, clean contact the ends of the pieces are ground on the outside for about 6 or 7 in. back from the ends, as in Fig. 8, the operator simply revolving the tube end against the grinding wheel. The ground pieces are sorted out into suitable lengths to form full-length flues when two pieces are butted together, keeping in mind that only two welds are allowed to a flue. A number of pieces sorted into suitable lengths for welding are illustrated in Fig. 9. These, when butt-welded and a safe-end welded on, will give a full-length flue with only two welds.

The welding is done on the butt-welder, shown in back and front views in Figs. 10 and 11. The machine itself is practically as received, but the inside mandrel and outside rolls, together with the driving mechanism, were added in the shop after considerable experimenting. Without these the method would be a failure.

A close-up view from the operating side is given in Fig. 12. The switch is carried on top of the post A,

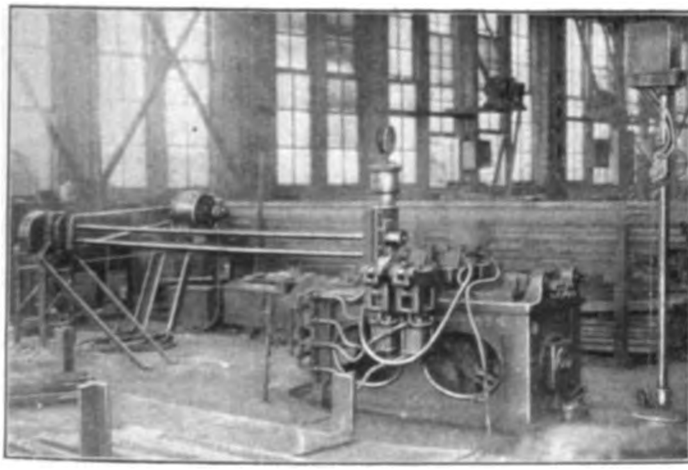

FIG. 10. BACK VIEW OF ELECTRIC WELDER

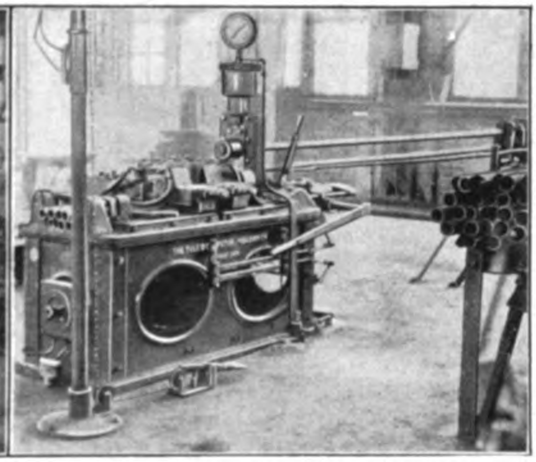

FIG. 11. FRONT VIEW OF WELDING MACHINE

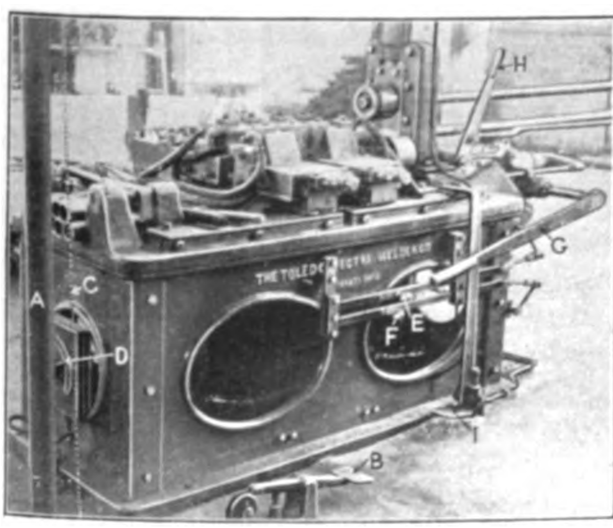

FIG. 12. THE OPERATING LEVERS AND FOOT TREADLES

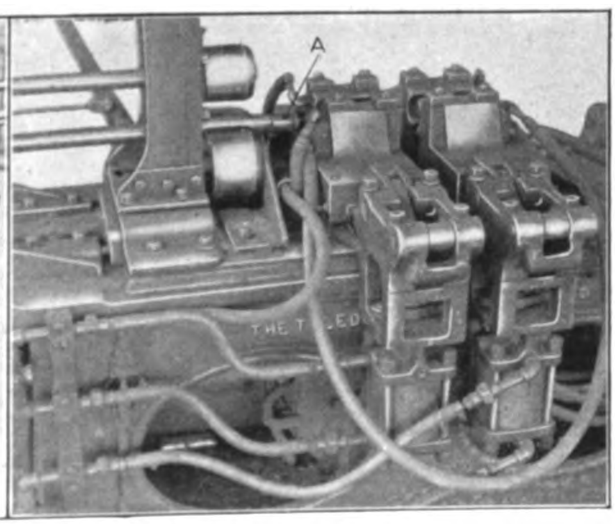

FIG. 13. MACHINE EMPTY, SHOWING THE INSIDE

and the welding current is turned on by means of the foot treadle B, which works the chain C. When a stronger or weaker current is desired, the amount is regulated by turning the pointer D. The gripping jaws, or electrodes, are air operated, the valves being worked by the handled slides E and F. The lever G operates the hydraulic apparatus used to bring the jaws closer together when butting the weld. The lever H works the clutch controlling the roll and the mandrel. There are three rolls, but only the upper one is power driven. The flue rests on the two lower ones, and the upper one is brought down by pressing on the foot treadle I, which works the air valve to the cylinder above the roll.

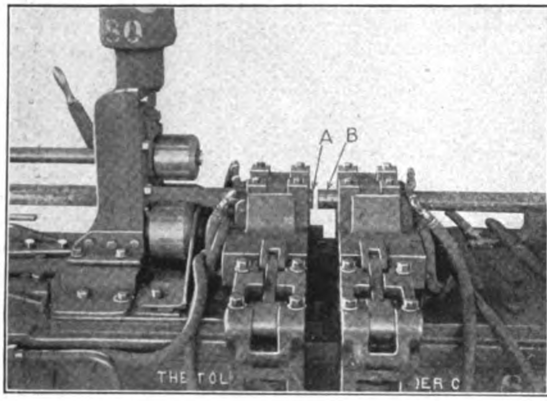

FIG. 14. FLUE PARTS READY FOR WELDING

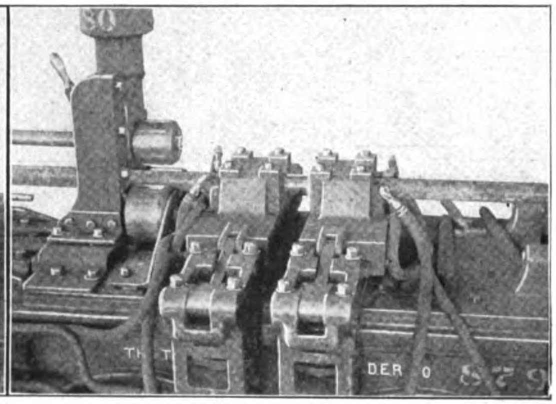

FIG. 15. FLUE ENDS JUST BEGINNING TO HEAT

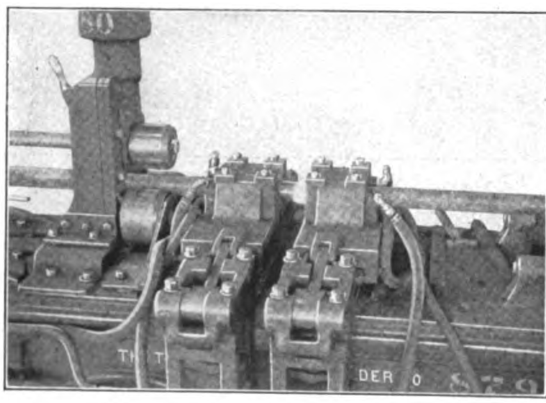

FIG. 16. ALMOST HOT ENOUGH FOR WELDING

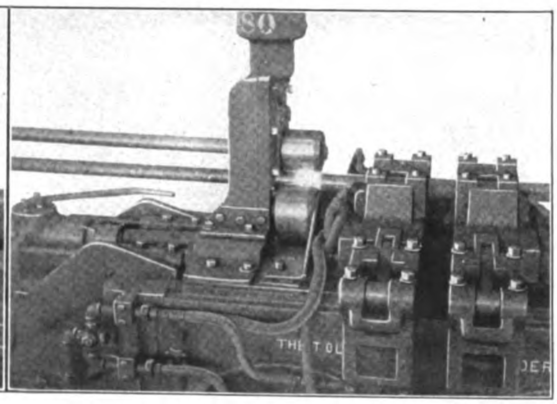

FIG. 17. ROLLING OUT THE UPSET METAL

Another view of the machine, from the back, is given in Fig. 13. This shows the mandrel A that works inside the flue as the outside is rolled between the three rolls after the parts have been heated and butted together. The action of the mandrel and rolls is to take out the upset and give a weld that is smooth on the outside and with very little extra metal inside. The gripping jaws are water-cooled, and the operating air cylinders are plainly shown.

Fig. 14 shows two parts of a flue in place in the jaws and illustrates how it is slipped over the mandrel. It will be observed that the mandrel does not extend far enough beyond the rolls to interfere with the welding or become heated from the current passing between the jaws. As it is impossible always to have the two parts to be welded of the same thickness, the setting of the pieces in the jaws must be done with judgment. If one piece is thinner than the other and they were both set in the jaws the same distance out, the thin one would burn before the thick one was hot enough to weld properly. To avoid this, a thick and a thin piece are placed about as shown in Fig. 14, A and B. In this case the thick one is at A and the thin one at B. As the thick one is in closer to the jaw, it will heat faster. The thin one, being set out farther, gives practically the same amount of metal for the current to heat. The result is an even heating and a perfect weld.

Fig. 15 shows two pieces the reverse of the ones just shown. As the work gradually heats, it looks as in Fig. 16. At the proper heat, the operator butts the work together to form the weld, which leaves a considerable amount of upset. He then shoves the tube along over the mandrel until the weld is between the rolls, when he throws in the clutch and brings down the upper roll. The work spins between the rolls, Fig. 17.

On flues made up in this machine the two parts comprising the main part of the flue are not only welded,

but the safe end is also welded on in the same manner. Fig. 18 illustrates some of the completed flues, and Fig. 19 some of the safe ends close up.

To give an idea of the perfect welds thus obtained, some of the welds were sawed apart purposely and are shown in Fig. 20. The weld on the outside can hardly be detected, and only a slight ridge shows on the inside. Welded in this way, there is absolutely no lump to cause trouble in passing through the flue sheet.

After being welded, the flues are tested under 100 lb. cold-water pressure in the apparatus seen in Fig. 21. This device holds two flues at a time. An air cylinder at *A* draws up a yoke carrying two cups that cover the ends of the flues. Water is then forced in; and while the pressure is on, the operator taps the welds with a hammer and carefully examines them for defects of any kind.

The flues welded are of the 19- and 20 ft. lengths and are 2 or $2\frac{1}{4}$ in. in diameter. About 250 welds per day can be made, on an average. With two welds to a flue, this makes about 125 flues reclaimed per day. Regular safe-ending is done on Hartz machines in the usual way, as the electric welder cannot handle all the work at present. The efficiency of the electric-welding method will be understood when it is known that out of three lots, selected at random, the failures were as follows: (1) 100, five bad; (2) 99, six bad; (3) 102, three bad. The general average will run about as indicated by these figures. After being tested, the welds are annealed to take any possible metal strains. They are then ready to go to the boilers.

Efficiency of Tool Steels

In a paper recently read before the Iron and Steel Institute, Prof. J. O. Arnold proceeded to show that not only is there no relation between Brinell hardness and lathe efficiency, but also that a plain carbon turning tool with very high Brinell hardness may, on comparison with another tool of considerably lower Brinell hardness, register an efficiency of practically zero, while the tool of about 15 per cent. lower Brinell hardness may run perfectly for 18 min. and during the last 5 min. of the test cut cleanly at a blood-red heat before breaking down.

The Brinell hardness of a properly hardened tool is an almost negligible factor of efficiency. The efficiency depends almost entirely on the thermal stability of the simple or compound hardenites in the hardened steel. The simple hardenite of plain carbon steel has a thermal stability of which the limit is certainly less than 300 deg. C., while the compound hardenite of a carbon-tungsten-chromium-vanadium high-speed steel may be rendered stable up to a temperature of about 700 deg. C.

The Rolling Stone Gathers the Shekels

By John R. Godfrey

Of all the various kinds of pure and unadulterated bunk handed out to the young engineer or mechanic the particular brand that urges him to stick everlastingly at the job and so gather the reward of diligence is unfortunately about the worst specimen that can be found. While it is probably true that the rolling stone rubs some of the bark off the corners and spends a few extra dollars in carfares and moving-picture shows, in most cases he seems to have more money to spend and is at least as well off at the end of the year. At least, that is the experience of a number of men whom I know of various ages and occupations.

Two particular instances come to mind; and while these by no means prove a rule, I can personally recall many others.

Bill Brown, for want of a better name, is a young technical graduate who has been knocking around the cold world for only two years. He took the first job available—puttering around in a machine shop, building printing presses and doing similar work at $8 per. According to tradition, he should have stuck to the job and mastered every detail, so that at the end of ten or fifteen years he might have been a general foreman, drawing perhaps $25 a week, if he was lucky. It so happened, however, that in about three months a gasoline-motor job happened along; and as he had previously "titrivated" balky automobile motors, etc., he was offered $15 a week.

Age and Earning Power

This developed into $18 and finally $20, and he was given charge of motor testing, with considerable designing and drawing-room work on the side. He was soon carrying quite a load of responsibility, working long hours and doing exceptionally good work. It did not particularly help his state of mind to know that he was holding down a job at $20 per which had previously been paying considerably more, nor was it altogether gratifying to be told that a boy of 22 couldn't possibly be worth more than that, no matter what he was doing. He, poor chap, in his ignorance, and despite his college education, seemed to feel that the firm was paying for work done and not for the number of years he had inhabited this vale of tears.

So when another man came along with an offer of $25 a week to assist him in working out the design of a new and experimental machine, coupled with easier hours, better working conditions and the promise of advancement despite his youth, Bill Brown was just foolish enough to take the job. Of course, the very fact that the shorter working hours and better conditions appealed to him in the least proved very plainly that he was of the mollycoddle type and not made of the sterner stock which we read about in books telling us how to succeed. In order to run exactly true to form he should have rejected the offer with scorn and stuck to the old concern, regardless of the hours and the pay envelope and grimly determined to stick it out on that line if it took ten years of his life, and so make them see his intrinsic worth.

But somehow the usual formula for success slipped another cog, and inside of two months the gas-engine firm was wiring him and sending special-delivery letters offering him $30 per week and all kinds of promises for advances if he would return to the fold. They even went so far as to suggest that the only reason for not offering him more to begin with was that they believed it was always well to have something to look forward to. They further assured him that the future remuneration could be very safely left in their hands, as they always rewarded faithful service without the necessity of even asking for a raise.

Upon being gently reminded that this was not the previous experience, they blandly assured him that the reason for not paying him any more previously was that he was not then worth any more to them. They quite forgot, however, to explain why two months' absence, in which his mind was fully occupied on entirely different work, should have increased his value 50 per cent.

Another case that comes to mind is a most successful works manager who a comparatively few years ago was a machinist running a lathe at the usual rate. He was a close observer and a hard worker and is today one of the best-paid works managers in this country. But he did not arrive at this very satisfactory position by sticking to one job and waiting for his ability to be recognized by his employer. He has probably not been in any one shop over four years, and in many of them he has stayed a much less time than this. But as an indication that bluff plays no part in his success, it may be interesting to know that he has been employed by one of the largest firms in his line at three different times, each time going back at a decidedly larger salary than the company was willing to pay him previously. In some ways it seems to be a case of "never missing the water until the wells run dry."

Even in the good old days some of the shops used to have the habit of discharging the apprentice as soon as he was out of his time and telling him to go elsewhere for a couple of years. This was not done especially for the benefit of the boy's pocket-book, but to add to his fund of shop experience, so that he would be of more value when he came back. But it was never advocated for men after they grew up; the rolling-stone formula began to apply about that time.

The Line of Least Resistance

There is something about the old adage that appeals to most of us, probably because it's so much easier to stick to one kind of a job than to float around from place to place. This is especially true if we have a flock of youngsters in school and the Missus has a whist club that she just can't bear to leave.

But the sad part of it is that in too many cases a man simply has to quit the old firm to get anywhere near what he earns. The "success" men (who generally have to pawn their shirts between checks they get for the articles they write about the matter) dope out a lot of hot air about growing up with the job, or ahead of it, but with too many managers it works in reverse gear. They never seem to wake up to the possibility of your being worth more until the other fellow offers you a job.

The companion exasperation to this is the game of "getting new blood" into the business by letting the old super resign and taking in a new man to improve things. The interesting thing is that he usually does. But when you boil it down, you find that many of his improvements are made possible by new machines that the old super asked for in vain. The new man gets many opportunities that were denied the old, and he makes a good showing.

Finding the Turning Point in the Small Shop

By John H. Van Deventer

SYNOPSIS—In the majority of successful shops there is one definite turning point at which a start is made toward bigger and better business. Many times this change is made unconsciously, and the turning point cannot be definitely located. In this case the installation of one machine changed the shop product from an average to an exceptional one.

A small shop that is 68 years old is something of a rarity and is therefore of interest in a country where plants mushroom over night as if under the spell of Aladdin's lamp. That a small shop can stand the buffetings and trials of 68 years of competition is also an interesting fact, establishing as it does that the small shop is after all of a hardy and robust nature. In an instance of this kind, one is apt to look for work a little out of the ordinary in order to account for such a long existence.

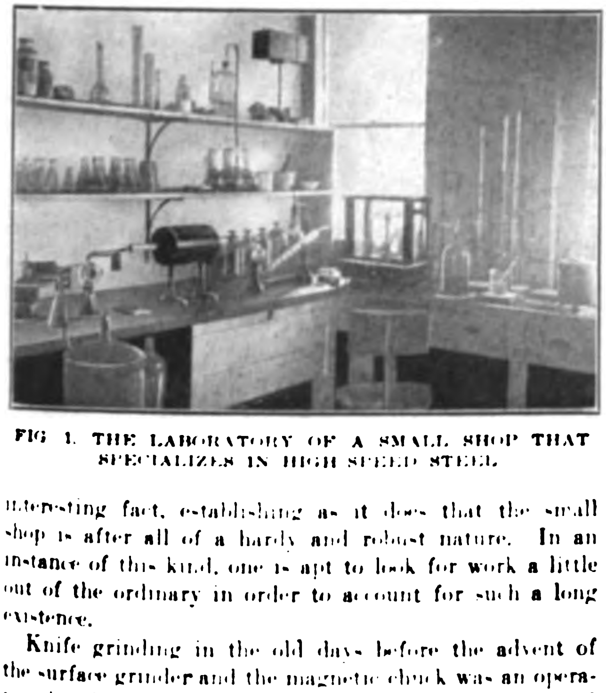

FIG. 1. THE LABORATORY OF A SMALL SHOP THAT SPECIALIZES IN HIGH-SPEED STEEL

Knife grinding in the old days before the advent of the surface grinder and the magnetic chuck was an operation in which the old fashioned grindstone and side wheel labored in partnership with a patient grinder hand who was unable with all his skill to grind anything really straight. Fifteen thousandths of an inch was considered a close job in those days. Most of the work was held and fed by hand, some of it in crude fixtures that were as likely to spring the knife out of shape as to hold it flat. Only those who have surface-ground thin stock by such means in the past can appreciate the real value of the magnetic chuck.

Prior to 1906 this was the way that A. Hankey & Co., Rochdale, Mass., were grinding knives. A rather ordinary line of work, one might say, and one that was not at all uncommon throughout New England, where knife grinding in America was indigenous.

A shop, in order to keep up with the times, must not only study its own progress and that of its competitors, but—and more important—it must keep in close touch with the progress and tendencies of its customers. Shops exist that are so bound up in themselves that self-interest is a far bigger factor than service, and other shops depending on these for a part of their products oftentimes find their own advancement hindered through a lack of someone's else initiative. At the time of which I have been speaking, when knife grinding was so crudely handled, a class of knife users of considerable importance consisted of the woodworking-machinery manufacturers. Compared with the present-day product, wood planers at this time were crude and slow machines. A feed of 25 ft. per min. was considered high and in fact was about the maximum that could be used for smooth work. Anything faster than this would show revolution marks on the finished board, the old four-square planer head with its thick, clumsy, hand-ground knives being almost impossible to balance perfectly.

One could not, without clairvoyant power, foresee that the 25 ft. per min. feed would some day be multiplied twelve times and that lumber would be shot through these machines at the rate of 300 ft. per min. But it was possible to arrive at the conclusion that an improvement in planer knives would mean an increase in planer feeds. Here was an opportunity for some knife-making shop to analyze conditions, find the weak point and help to push aside the obstacles holding back the progress of the wood planer.

The installation choice of a new machine is taken more seriously in the small shop than in the large one. No doubt this is because one machine among many does not affect the whole as much as when one is added to a few, just as a single vote in a small town is of much more relative importance in local elections than one vote in a large city. The installation of the wrong machine in a big shop means annoyance and a small loss; the installation of the wrong machine in the small shop may put it out of business. On the other hand, not buying a machine that is needed, while it will not result in a sudden calamity, is likely to terminate in a case of gradual dry rot.

The "Rogers Boys," as J. R. and Francis P. Rogers, Jr., are known in Worcester and vicinity, believed that a suitable surface grinder would solve a problem of the wood-planer knife. Not only had they the conception of what was needed, but not finding a suitable machine for this purpose on the market, they designed and had built the special machine illustrated in Fig. 2—an act that involved playing a $10,000 stake against their belief. That this was an investment and not a gamble is evidenced by the fact that from this machine came the first high-speed steel wood-planer knife made, and others have been coming from it ever since.

This machine is of interest, not only as an example of good judgment displayed at an opportune time, but also for what it will do. The grinding wheel is 24 in. in diameter with an 8½-in. face. Running at 5,000 ft. per min. it is so free from vibration that one cannot tell whether or not it is in motion, even when holding to

his ear a screwdriver with its end applied to the wheel bearing.

The table of this machine is 10 ft. long, its entire length being equipped with Walker magnetic chucks having a width of 8½ in. There are two table speeds—40 and 60 ft.—one for roughing and the other for finishing. On the class of work produced on this machine, limits and finish are held exceptionally close, some knife specifications calling for tolerances no greater than 0.00025. In view of this requirement the accomplishment of this machine in removing $\frac{1}{32}$ in. per hr. from a surface 120 in. long and 8½ in. wide is rather remarkable. The table is reversed by a pneumatic clutch.

The rear view of this machine, seen at *B*, displays 2½-in. flexible steel hose through which cooling water is applied to the wheel. When the machine was first tested out, this hose was not fastened as securely as is shown, but was held by a husky negro who directed it upon the back of the wheel. The gentleman, becoming absent-minded during the course of events, allowed the nozzle to deviate from its proper path; as a result the 2½-in. stream projected between the housings and knocked a couple of interested spectators from a bench alongside the table. What happened to the spectators is known, but what happened to the darkey is not related.

One does not see anything unusual in the practice of saving the sweepings from the floor of a mint in which gold coins are being made, but it is rather strange to find a similar practice in a knife shop. However, when you consider where the price of high-speed steel is today and where it is quite likely to go, there may not be much to be wondered at after all. The accumulation of dirt shown in the tank at *A* in Fig. 1 is in reality high-speed steel grinding dust floating on top of water. This material is carefully saved, packed and shipped to the steel mills, where every bit of tungsten is eagerly welcomed.

One can get an idea of the proportions of a high-speed steel wood-planer knife from the illustration at *A* in Fig. 3. They are from ⅛ to $\frac{3}{16}$ in. thick, from 1½ to 2 in. wide and from 4 to 50 in. long. The heat-treatment and straightening of a high-speed steel blade of such proportions require a high degree of skill. All these blades are hardened in Kenworthy furnaces using fuel oil vaporized by steam under a pressure of 125 lb. and are quenched in Houghton's soluble quenching compound. After quenching, they are tempered, or "let down," to approximately 600 deg. F. Before this, however, they must be straightened, a peculiar thing about high-speed steel being that it is impossible to straighten it after this second heating.

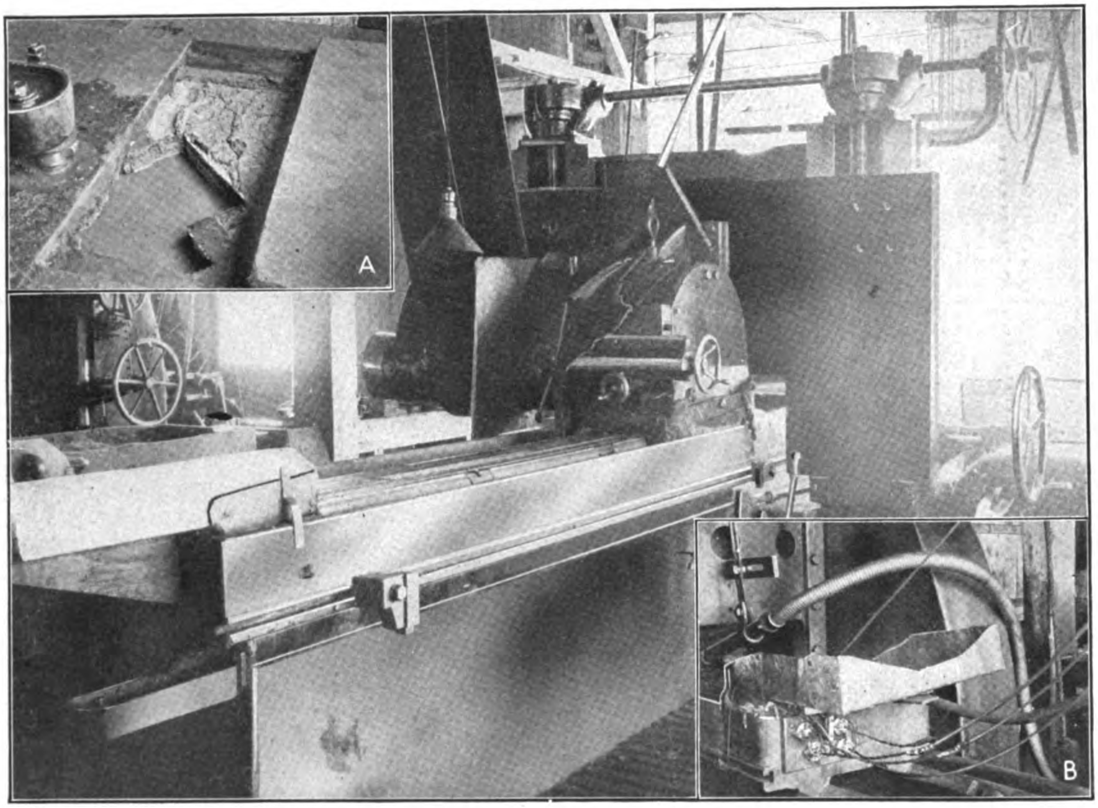

FIG. 2. THE SURFACE GRINDER THAT PROVED TO BE THE TURNING POINT

Planing Iron at 230 Ft. per Min.

The machine-shop man who has been unpleasantly surprised by the ease with which some high-speed drills and reamers break under slight provocation would expect a thin high-speed steel knife of this kind, hardened to a scleroscope hardness of 85, to be a rather delicate and fragile tool. He would change his mind if he could see

the piece of 1½-in. angle iron shown at *B* in Fig. 3, which was accidentally fed into a double surfacer and planed both top and bottom for 18 in. of its length at a speed of 230 ft. per min., some ⅜ in. in depth being removed from one of the ribs and a full $\frac{1}{32}$ in. from the entire surface of the other rib. The high-speed steel knives which did this fast iron planing were somewhat dulled, to be sure, but a grinding put them in condition for further cutting of lumber.

Before the installation of this "turning-point machine" the Hankey company was doing what a number of other firms were also doing and in about the same way. The use of this machine upon high-speed steel knives, however, necessitated careful study of the heat-treatment of this material and led to a specialization in accurately ground high-speed steel knives and tools, which has been

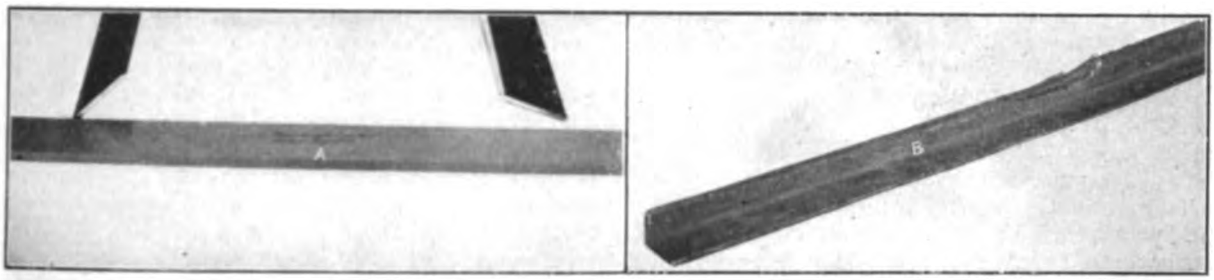

FIG. 3 HIGH-SPEED STEEL WOOD PLANER KNIVES AND WHAT THEY DID TO ANGLE IRON

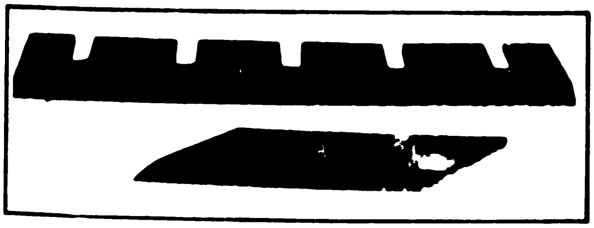

FIG. 4. COMPOSITE-STEEL WOODWORKING KNIVES

a profitable line of business. But the turning point was the installation of the grinder.

High-carbon and composite-steel tools and knives are also heat-treated and ground at this plant. Two of these are shown in Fig. 4, the one at *A* being a wood planer knife for a square-cutter head and the one at *B* being a miter knife. They have soft steel backing on tool-steel edges. The furnace weld is rolled, and the grinding of a piece of this kind, one part of which is soft and one part hard, without leaving a mark at the junction of the two pieces may be considered a noteworthy job. In fact, the face of these blades must be ground to a radius, that is, held to very close limits. One and one-half thousandths is allowed for location of this radius centrally with the blade, and 0.001 in. is allowed on the length of the radius.

It is not often that a small shop is able to change the grade of its product as markedly as this, owing to the installation of a new machine. Every small shop, however, can keep in mind the fact that each machine installed should be a turning point toward better work and more profits.

This thought, coming at the time when new equipment is to be purchased, will influence the buyer to select the machine best suited to his needs regardless of what its cost might be.

Financial Literary Rewards

By R. D. Gatewood

Many readers have no doubt had occasion to comment on the apparent lack of financial reward to literary labor, particularly that involved in writing technical articles. Not one writer in 50 can live on the earnings from his literary efforts, yet it is an undisputed fact that other professional men—physicians, lawyers, consulting engineers—can sit in their offices and take in as a single fee for a service that costs them an hour's time a sum equal to that which an editor works a month to win. Surely, it takes almost as much time, money and labor to fit a man thoroughly for one profession as for another; and I may add that it requires just as much talent and genius to be a successful technical writer as to be a doctor, a lawyer or an engineer. In the character of work done and in the amount and kind of preparation required there is little reason why one of these professional men should be better paid than another, yet there is no field of human effort where the contrariety of pecuniary reward is more pronounced than that presented by professional and literary labor.

After all, the monetary compensation for this kind of work is fixed by the great law of supply and demand, and technical men with literary tendencies must find their true reward in some such thoughts as the following: Every technical man who can do good, marketable literary work along the line of his specialty owes a certain duty to his profession and his generation to record the results of his own experience.

A certain professional respect is usually accorded him by his fellow workers, especially if his articles contain anything of an original nature. The effort to present his subject in a clear, concise way nearly always results in giving the author himself a clearer view and better grasp both of his particular subject and of the engineering profession as a whole.

These are some of the compensations of doing literary work for technical magazines; and if more consideration were given them, fewer writers would permit their literary tendencies to die out, and more men would enrich their profession with an expression of their views.

The Growth of the Aëroplane Industry is indicated by the exports of 398 aëroplanes for 1915 against 40 in 1914 and 19 in 1913. The value of the 1915 exports was $2,960,814, or an average of $7,439 per machine, against $6,337 in 1914 and $3,227 in 1913. The exports of aeroplane parts were also very large, amounting to $2,457,782 as compared with only $145,997 in 1914 and $25,606 in 1913. Imports of aeroplanes into the United States decreased from 16 and 13 in the fiscal years of 1912 and 1913 respectively to only one each in the fiscal years of 1914 and 1915.

Punches and Dies for Making a Gate Wearing Shoe

By Robert Mawson

SYNOPSIS—These tools are made of cast iron and are put into service without any finish whatever. The scale provides a hard wearing surface for the bending or forming operations. The stock is heated in a furnace before being bent.

On page 894 are shown some cast-iron punches and dies designed and used by the Narragansett Machine Co., Providence, R. I. Other similar tools are illustrated and described in this article. It will be observed that the tools are of somewhat simple construction; and as the stock is of a rough character, adjustable locating surfaces are employed. The tools, as well as those previously discussed, are giving satisfaction, producing parts quickly and accurately.

Cast-iron punches and dies have not been used very extensively in the forming of machine elements. For most punches and dies either machine steel or tool steel is employed. When the former is used, it is necessary that much accurate machining be done. Often when the shapes are rather intricate, the punch and die must be made in various parts which are then fastened together with setscrews and dowels or similar mediums. In manufacturing some punches and dies many companies employ cast iron as the base of the die, on which is fastened a tool-steel die plate. When this method is followed, the die bed must be accurately machined, and after the tool-steel elements have been made, it must be hardened and ground to the required contour.

The hardening process is to many firms somewhat of a task, and unless care is taken it tends to warp the tool-steel element. This change in shape must be remedied by the subsequent grinding operation. In the making of the punch a somewhat similar procedure is followed. The shank and body of the tool are usually made from machine steel, which must be machined. The tool-steel punch must also be machined, hardened and ground. The change of shape in this element must be remedied in the same way as in making the die.

After the tool-steel element has been accurately ground to the correct contour, it must be attached to the shank base by means of screws and dowels. It will be observed that tools made in the manner described call for a high grade of tool making. It takes a long time to complete the tools, and the punches and dies produced are therefore costly. It is true, however, that tools made in this manner usually give extended service.

On the other hand, many of them break, and their upkeep is quite an item in the shop equipment. In the bending and forming of many of the simpler elements on machines cast-iron punches and dies may be employed to advantage. For such tools the design made in the drawing office must give a tool strong enough to resist any strain brought upon it by shop practice. No allowance is made for finish, unless it be on the shank.

This part, however, may be molded smooth enough to fit the press without machining and thus reduce the cost of the tool to the lowest figure. The castings are made from the pattern and, as mentioned, are not machined. This is an advantage, as the skin on the cast iron provides a hard surface to resist any wear during the use of the tools.

It will be noticed on the first two tools shown that adjustable stop screws are employed to locate the steel strip, which has been previously cut to length. In operation the stock is slid against the inner edge of the screw, and the punch, being fed down, produces the contour desired. The last tool performs two operations. The first of these is to produce a bend on the flat side. The heated plate is then placed in the slot, and by feeding the punch down a second time the bend is made.

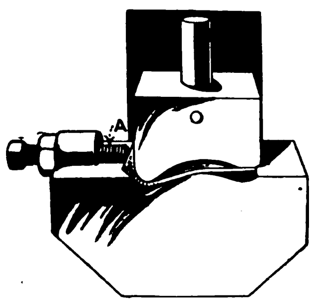

FIG. 2

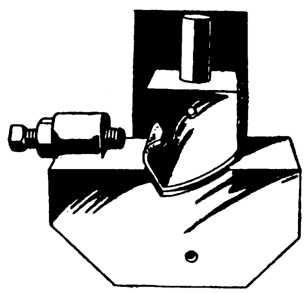

FIG. 4

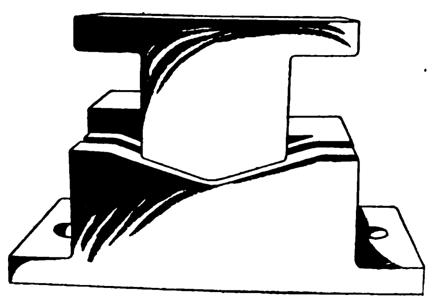

FIG. 6

PRESS TOOLS FOR MAKING A GATE WEARING SHOE AND SIDE HANGER

FIGS. 2 AND 2-A

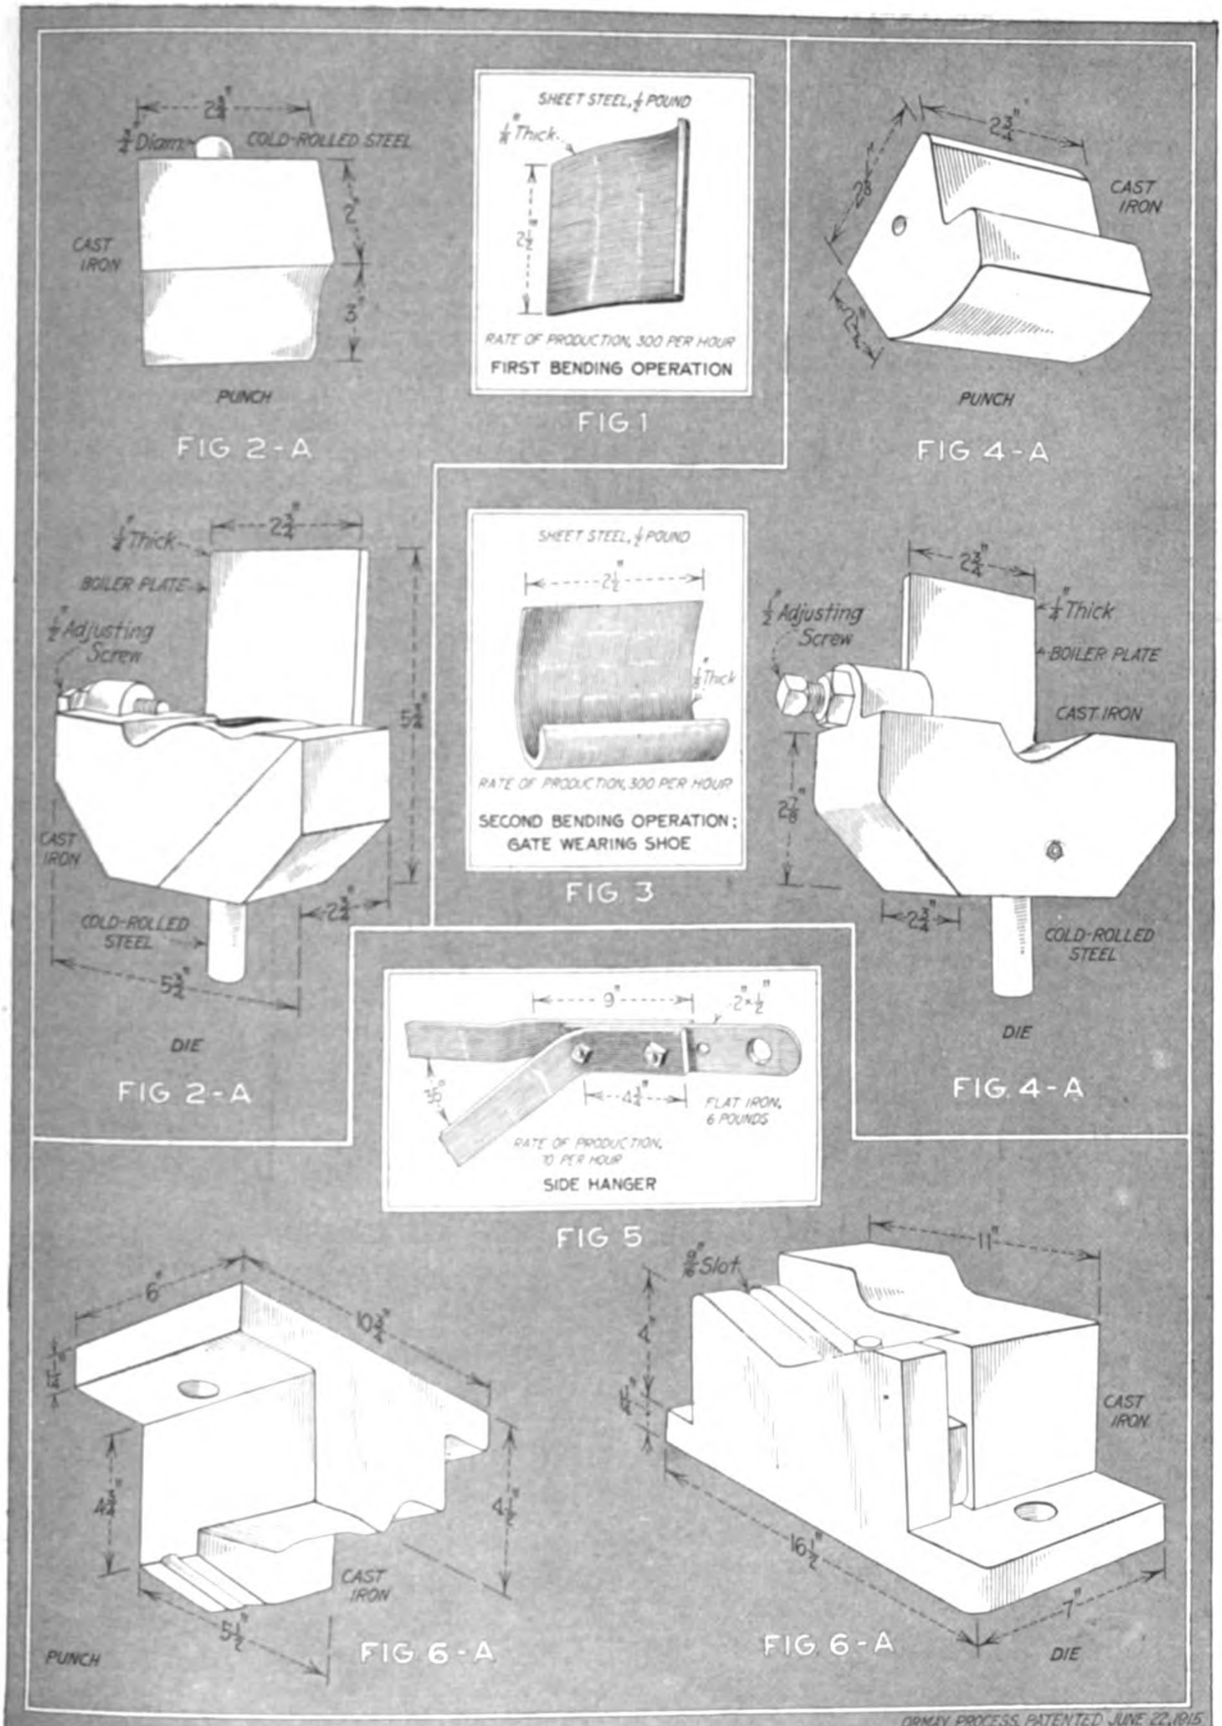
Operation—First bending operation on gate wearing shoe, Fig. 1. The stock, which has been cut to length, is placed on the die against the adjustable screw A. It is formed to the required contour by the punch, which is fed down.

FIGS. 4 AND 4-A

Operation—Second bending of gate wearing shoe to the form in Fig. 3. The part is placed on the die, being again located by the adjustable screw, shown. The punch is fed down by the press, giving the element the desired shape, as illustrated.

FIGS. 6 AND 6-A

Operation—Bending both elements to make a side hanger. One plate is placed on the die and the bend on the flat side of the first element is made. The other part is placed in the slot of the die, and by feeding down the punch a second time the edge bend is made. Thus the tools are used for bending both bars complete in two operations.



DETAILS OF PUNCHES AND DIES FOR MAKING A GATE WEARING SHOE

Russia and America--Economic Doubles

By Edwin Francis Gay*

In an economic sense, Russia and the United States are more alike than any other two great countries of the world. Underneath their wide differences of language, government and religion these two countries show fundamental similarities. Russia includes the eastern portion of the great-plains area of the northern hemisphere; America the western portion. Both have had a history of agricultural pioneering. Both have great natural resources of fertile land, forests, and mines, which have been drawn upon with the pioneer's inevitable prodigality.

Russia and America are the two wings, so to speak, of the great movement in economic development which originated in western Europe a little over a century ago, and thence has spread eastward and westward. They both borrowed from this center the new technical equipment of machinery and power for production and transportation, and adapted it to their similar needs.

In this borrowing and adaptation the United States has preceded and has in turn influenced Russia. It is no accident, for example, that the river steamers of the Volga are like those of the Mississippi, nor that railroad construction and equipment are similar in the two countries. In both, railroads had to be built as cheaply as possible, through long stretches of sparsely populated territory; and Russia has consciously adopted the solution of the problem that was found by American engineers.

The factory system and machine production were transplanted in both cases, though earlier across the Atlantic; and the infant industries of each country have called for protection from the competition of the more mature and proficient central nations. It is again no accident that these two countries, the eastern and western outposts of the industrial revolution, are alike in raising the highest protective tariffs.

Since from an economic point of view these regions are new areas of development, demanding capital greater than they could themselves supply, they have borrowed abundantly from the older centers of accumulation. The United States and Russia, therefore, are the two great debtor countries, and as such must export commodities to pay for the interest charges and for other services rendered. It is in consequence of this debt relationship that they each have an excess of exports over imports; they each show what is misleadingly called a "favorable" balance of trade.

*Dean of the Harvard Graduate School of Business Administration.

Both countries have been somewhat similarly affected by the western European current of economic and social thought. The high tide of Liberalism at the middle of the nineteenth century led them, among other changes, to temporary tariff reductions and to agrarian reform. The liberation of the serfs in Russia and the freeing of the slaves in the United States were contemporaneous.

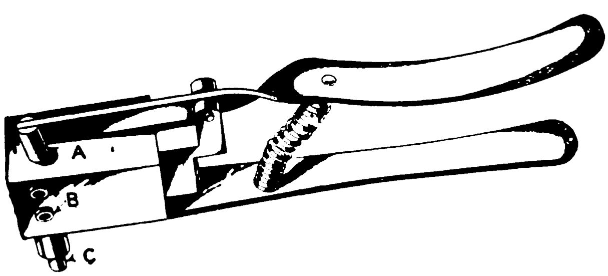
The fundamental parallelism of economic development shown in these and many other aspects of national life is especially marked in the agricultural basis of foreign trade relations. During the last half-century both countries have been absorbed in the economic subjugation of great continental areas; of necessity they have been hitherto land powers rather than sea powers. Their exports have consisted chiefly of agricultural products, and despite high tariffs they have offered large and profitable markets for the importation of manufactures and luxuries from western Europe.

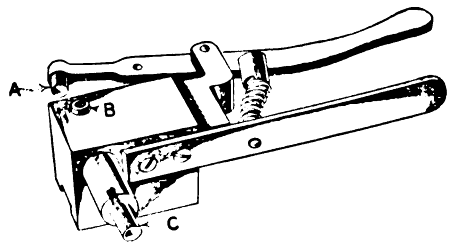
This similarity of commercial position does not, however, indicate any necessary antagonism of trade interests between the two countries. The development has throughout proceeded somewhat more rapidly in the United States, which in consequence of this development is nearer than Russia to the end of the great period of foodstuff exports and capital indebtedness. The United States will hereafter be increasingly able to supply Russia with manufactured goods, especially with agricultural machines and tools, tractors and machine equipment for its industrial plants.

It is important for American manufacturers to study the Russian market and to encourage reciprocal trade relations. The United States is entering upon a new era in its economic life. As a manufacturing nation, it cannot longer be a merely passive trader, but must actively seek foreign outlets for its wares. As a nation, we are as yet far from realizing our need of thorough training for this new work, and we must perhaps be disciplined by hard experience. Economic necessity will force upon us closer international contacts, both commercial and political. In Russia we find a power which in our national history has been consistently friendly to us and which now offers an inviting field for American business enterprise.—*Russia.*

Small Pin-Drilling Jigs

Two drilling jigs, used in the shop of the Henderson Motorcycle Co., Detroit, Mich., for drilling crossholes in small pins, are here shown. The pins to be drilled are thrust into bushed holes in the body of the jigs and are held in by the spring levers *A*. The drill guide bushings are shown at *B* in both jigs. The pins are removed by squeezing the handles and hitting the knockout pins *C*.





TWO SMALL PIN-DRILLING JIGS FOR MACHINING CROSSHOLES IN CYLINDRICAL MOTORCYCLE AND OTHER PARTS

Afterthoughts on the Panama-Pacific Exposition

By Frank A. Stanley

SYNOPSIS—A review by a writer who has visited many large expositions, pointing out salient features which might be overlooked by the casual visitor. The large attendance, the success in designing unusual buildings and keeping them clean and attractive, and the direct sales and future business secured by builders of the few machine tools exhibited are all of a special interest. The growth of machinery for preparing and packing food products is also shown and is far greater than we are apt to realize.

Since the close of the Panama-Pacific International Exposition at San Francisco, Calif., I have asked a good many of my acquaintances, engineers, manufacturers, business men and others who had the privilege of visiting the fair, what they considered the most important, the most interesting or the most striking feature of the exposition.

Quite naturally, there have been almost as many different answers to the question as there were persons to whom the query was put; and quite as naturally also, the replies have depended somewhat upon whether this exposition was the first one attended or whether visits had been made to earlier great international shows, so that the observers had had an opportunity for making comparisons between the San Francisco exposition and those at St. Louis, Buffalo, Paris, Brussels, Chicago and other cities.

It is rather difficult, even for a sophisticated newspaper man accustomed to visiting all the world's great shows as they come along, to determine what most impressed the majority of visitors at the Panama-Pacific Exposition. This having been a contemporary exposition, necessarily some of the most striking exhibits at earlier fairs were eliminated; yet without doubt historical exhibits showing the evolution of certain industries have in the past constituted almost, if not quite, the most attractive and instructive displays at international expositions. Among such as may be recalled have been the historical railroad exhibits showing the development of modern locomotives and cars from the primitive rolling-stock of over a century ago; the progress in steamship construction; the growth of design and manufacture of various lines of machinery; the evolution of heavy ordnance, firearms and the like; and the change and improvement, revolutionary in most instances, that have occurred in numerous other lines of activity.

Eliminating from the San Francisco exposition such interesting displays of former days, historical in their character and far reaching in their educational influence upon visitors of all ages, what then were the dominating features at the fair which closed last December?

Considering the exposition as a whole, its compact arrangement, its artistic design in grouping of buildings, its novel and more than pleasing color scheme, its unique system of illumination throughout the grounds, its general atmosphere of neatness and cleanliness—for there were no scrap heaps, dumps, garbage piles or other disagreeable and unsanitary and unsightly features to be found at the rear of the buildings or along unimportant passageways—were all factors in causing this exposition to be considered by trained observers the most attractive one yet produced in any city of the world.

From an engineering point of view the show had its shortcomings in many respects, as might have been expected, due to certain conditions which from their nature seemed insurmountable. In the first place, San Francisco itself, lying at the extreme western point of the continent and situated in a state numbering less than two million and a half population and over two thousand miles away from the center of population of the United States, seemed to many, prior to the opening of the fair, to be too far away to attract any special attention from a considerable number of people who would have decided unhesitatingly to visit an exposition held nearer the geographical center of the country. The great European War, manufacturers busier than ever, the expectation that a comparatively small percentage of people in this country would attend the exposition, that an almost negligible number would come from abroad and that consequently a big expense account would very likely have to be borne by exhibitors, particularly from the East, with little likelihood of any commensurate return either in immediate or future business, decided the majority of machinery builders not to exhibit at the exposition.

Experience of Exhibitors

Whether this policy, viewed from a broad standpoint, was a wise one need not be considered here. The fact remains, however, that to the astonishment of everybody the attendance at the exposition was not only far greater than ever anticipated by the most optimistic Californian, but even exceeded the total attendance at any of the former expositions held in this country, with the exception of the Chicago fair of 1893. Such machine-tool builders and dealers as did have displays, as well as numerous exhibitors of other lines of machinery who were interviewed during the closing days of the exposition, all expressed themselves as more than satisfied with the outcome of their endeavor toward making the fair as representative as possible of our national industries.

Not only did they have in each instance a far greater number of interested visitors than anticipated, but more to the point, their exhibits were productive of much real business. In several cases I was told by machine exhibitors that they had developed a large amount of entirely new business in what to them was practically a new territory. In certain instances the entire exhibits were actually sold on the spot, together with additional similar equipment to be shipped from the home factories, as a direct result of having gone to this Coast exposition with a fairly full line of their products. In the cases referred to, the exhibitors found themselves immediately reimbursed financially for the expense to which they had

been put in shipping to the Coast and maintaining their exhibits throughout the ten months of the exposition and made a fair profit in addition.

Beyond this remains the fact that a considerable and growing amount of new business was opened up with certain machines heretofore little used or known in the Far West, so that the sales made at the exhibit constitute but a part of the business resulting as a direct outcome of manufacturers' exhibiting their tools.

In this connection it is of interest to mention the experience of one tool builder from the Middle West, who had a liberal display under his own exhibit. He stated that, never before having visited the Pacific Coast and having had in his years of manufacture a relatively small amount of business in that section, he was somewhat disinclined to go to the expense of filling space in Machinery Palace. Upon second thought he decided that as an American citizen he would make the venture and do his little part toward making the exposition truly national and not sectional in its character, so far as relates to the United States. In his case at least the fulfillment of what he felt to be an obligation and a duty brought a financial return which could hardly have been expected by most optimistic exhibitors at the outset. Tools of the very kind he was showing were wanted immediately in the near vicinity, were purchased during the exposition period, and he was relieved of the burden of shipping back home. The transaction ran into such an amount that he was at once able to show a good profit over and above the expense to which he had been put as an exhibitor.

Attitude of Machinery Builders

In visting the San Francisco exposition I followed the policy adopted at former international expositions of arriving not far from the closing date, when exhibitors have had ample time to review thoroughly the outcome, financial and other, to themselves and business friends; when the earlier enthusiasm, so far as any enthusiasm had existed, has diminished or worn away; and when a fairly accurate consensus of opinion from all sides and angles bearing upon the show may be obtained. On all past occasions I have been assured by various manufacturing friends that they had had enough of big shows, that such exhibitions were not worth while from a business point of view, that they were through for all time with such expositions except as casual visitors. In most cases, to be sure, there was a change of heart in the course of time, and usually the next exposition fortunately found these same manufacturers present with their displays of newer and better lines of machines. At San Francisco, probably in part for the reason just given and in part for the peculiar conditions obtaining at home and abroad, previously referred to, the great majority of our machinery manufacturers were not represented. But from those who were there as exhibitors I heard no complaint that the venture had not paid from any point of view as in the past, or that this was the final appearance for them as participants in a big exposition.

It is my firm opinion, based upon observation and upon the results of numerous interviews with exhibitors, that those who showed at San Francisco will, with possibly a few exceptions, be optimistic participants in our next great international exposition, no matter in what part of the country it may be held.

Professor Larkin, of Mt. Lowe Observatory, has pointed out that at this exposition the highest achievements in the history of man were exhibited. He refers in this connection to five of the greatest inventions emanating from the brain of man, these being the diffraction grating, the telegraphone, the Audion amplifier, the wireless telephone and Thordarson's transformer for one million volts.

These devices, wonderful developments in the scientific field and each of wide importance, were in spite of their value probably examined by a comparatively small number of visitors. It is doubtful if even a small percentage of people outside of the engineering and scientific fraternities knew of them or heard that they were exhibited. For most people at an exposition of this kind wander about through building after building in an aimless, undirected fashion, glancing at everything along the main aisles, seeing nothing particular in detail. They eventually leave the grounds in a semidazed condition, knowing that they have seen many new objects, but unable usually to describe any special feature. They have seen the show as a whole and seem well content with their experience.

On the other hand, visitors who go with some fairly definite object in view find that, with a somewhat limited amount of time, while they see much of interest in their respective fields they are never able to make a complete round-up of all the exhibits which they have in mind as worth examining. It yet remains for some progressive individual to develop some form of itinerary, some fairly simple routing process by means of which people going to an exposition to study certain lines of advancement in the respective arts and sciences in which they are interested may with a minimum of time and effort see every exhibit likely to be worth while to them.

Undoubtedly the most interesting engineering exhibit from a popular viewpoint was the great working model of the Panama Canal, this model covering an area of nearly four acres and being produced on the scale of 1:600 horizontal and 1:150 vertical. The amphitheater in which the model was installed was so built that the water level was about 20 ft. below the spectators, so that a clear birdseye view was obtained of the surrounding country as well as of the canal itself.

The operation of this model included the passing of vessels of various kinds through the canal and locks and the running of trains over the Panama R.R. All details were worked out so thoroughly as to include lights and channel buoys, range towers, etc., the whole affair being electrically operated.

Coming as it did to commemorate the opening of the canal across the Isthmus of Panama, the San Francisco exposition had in this one feature of the canal model an exhibit unsurpassed at any previous world's fair. It is doubtful if as much money has ever been spent on any engineering undertaking in the history of the world as on the carrying out of the work of the construction of the great canal. And the opportunity to witness the operation of the large-scale model at San Francisco was appreciated by hundreds of thousands of visitors, the greater portion of whom are naturally so situated as to make it impossible for them to visit the canal itself.

While machine tools, textile machinery, engines and so on were shown in relatively small numbers, there were numerous examples of striking development in machine

construction since the last international exposition—among these, Diesel oil engines, certain types of motors, electric apparatus, farm implements and automatic and semiautomatic machines of various kinds.

One of the most important developments in the machinery field during the past few years is the equipment for manufacturing, handling and packing food products of all kinds. Can-making machinery has long been on the market, and it is fairly familiar apparatus to designers and mechanics in general. But of later lines of equipment for preparing foods and containers less is commonly known. At the time of the World's Fair in Chicago in 1893 few of our modern patented breakfast foods were on the market, and not until about the time of the Louisiana Purchase Exposition in St. Louis in 1904 was any appreciable amount of machinery developed for the preparation in packing of these articles of diet now so common in every household. The ten or twelve years past have seen an amazing extension of new food preparations and a still more wonderful development of mechanical apparatus for their manufacture. Then, too, in the period referred to, methods of preparing and packing old standard lines of food like fish, meats, fruits, vegetables, cereals and the like, coffee, tea, cocoa, milk and so on have been revolutionized. At San Francisco, for the first time was a really complete line of machinery for this important work on exhibition.

Food Machinery Most Ingenious

The history of the origin and evolution of such apparatus is a most interesting one, involving the design and arrangement of new combinations of mechanism for handling materials which, before, it had always seemed impracticable to deal with except with simple crushing, rolling and steaming apparatus and in many cases with hand labor alone or with the simplest forms of hand appliances. Labor in this field had always been of the cheapest, the work often carried on at home or in small factories by children or by older people oftentimes not otherwise employable. With the development of new forms of food products there sprang up a corresponding development of ingeniously designed machinery for their preparation, and coincidentally mechanical apparatus began to be devised for application to the handling of older foods and tending toward the elimination of the cheap unskilled labor in that particular activity.

This machinery embodies as a class not only some most intricate and interesting mechanism, but also a degree of workmanship not excelled in many of our finest machine tools and other equipment of precision. It is rapid in its operation and it is kept scrupulously clean mechanically, so that its product emerges in incomparably better condition for consumption than would otherwise be possible, even granting that it might be practicable to produce certain of these preparations at all except by this mechanical process.

It is a far cry from Providence, R. I., in the year 1894 to San Francisco, 1915. Nearly a quarter of a century has passed since in the former city were built what were probably about the first of the automatic machines for manufacturing breakfast foods, and these may be considered the pioneers in the now long line of highly developed apparatus for such operations, most of this equipment having seen its evolution during the past ten or twelve years at the outside.

In 1893 the shredded-wheat preparations now made at Niagara Falls were first patented, and a number of special machines were built for manufacturing these foods in large quantities. The following year I, a young journeyman machinist in the Brown & Sharpe shops, with three other young mechanics on a battery of four Reed engine lathes, was put to work on the job of turning out a considerable number of grooved tool-steel rolls for a lot of wheat-shredding machines which the firm had taken to build on contract. And these machines had to be built with a high degree of accuracy throughout.

The rolls for these machines were of Jessop steel, and as nearly as I can remember they were approximately 5 in. in diameter, 5 in. long and weighed about 25 lb. each; they were bored for a $1\frac{1}{4}$-in. shaft, or spindle, and were relieved in the bore to leave a bearing surface at each end about 1 in. in length.

The steel blanks, well annealed, were first rough-bored on a vertical chucking machine, rough-turned to within, say, $\frac{1}{16}$-in. diameter and then brought to me at the head of the lathe crew—head, not in authority, but in the position of my lathe, which stood nearest the chucking department. It was my part of the work to bore the hole to size, turn the diameter accurately, face the ends down to an exact overall length and pass the blank along to the other men, who divided among the three lathes the roughing down of the series of fine grooves around the circumference of the roll—these grooves being spaced about $\frac{1}{16}$ in. apart and having a V-form about like a U.S.S. thread—and the finishing of the roll surface and grooves with a flat-form cutter extending the full length of the roll face.

Handling a Chuck Job

Although there were a good many rolls to be made for the shredding machines, it was hardly necessary to make any lathe tools for the purpose, except the flat grooving cutter referred to. The roughed blank as it came to the first lathe was placed in an independent four-jawed chuck, trued up fairly closely, a light cut turned at the outer end for about an inch to receive a steadyrest and a similar light cut turned at the inner end as near the chuck jaws as possible. With the steadyrest supporting the end of the blank, a tool was applied to face the end of the roll square, and the outer end of the hole was bored a dead fit to a plug gage, the bearing thus formed as far as the recessed portion of the work having, as already mentioned, a length of about 1 in.

Next, the roll was reversed end for end in the chuck, the other end supported in the back rest and the chuck end trued accurately with a test indicator. The exposed end was then faced off true and the outer end of the hole bored to the plug-gage fit just as the other end of the hole was previously bored. The test of the alignment of the two bearing surfaces thus bored from opposite ends of the roll was that a hardened and ground arbor with the very slightest degree of taper must pass straight into the work with perfect fit, just as if the roll had been bored straight through from end to end at one setting.

While this process requires quite a bit of explanation, it was easy enough to follow out in practice; and the bore was much more quickly and easily finished to exact size than would have been the case had the attempt been made to run a slender boring tool clear through from

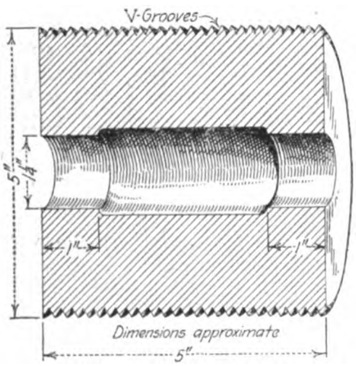
front to back. With a chuck in first-class condition, it is always a fairly simple matter to indicate with accuracy a piece of work of almost any reasonable size and form. The experience derived at this time was useful for many years afterward, and I have never since worried over a job of chucking.

Following the facing and boring of these rolls, they were placed on an arbor, turned to size to a vernier caliper, faced exactly to length to another vernier—for large-size micrometers were not available in those days—and the rolls were then passed along to the grooving lathes.

In preparing the finished rolls for assembling in the shredding machines they were forced onto spindles which were hardened and ground, the journals being fitted in bearings finished with the same degree of precision as the rolls themselves.

Shop Happenings

Two peculiar incidents occurred during the carrying out of this contract which oftentimes bring these details to mind at the breakfast table: The long serrated forming tool for finishing the V-grooves in the rolls was originally made in one piece about ½ in. thick. It was clamped fast to the top of a flat holding block on the



ROLL DETAIL FOR WHEAT-SHREDDING MACHINE

cross-slide of the lathe. It was thus left clamped in place one Saturday afternoon; and the following Monday morning, after a marked reduction in temperature over Sunday—this was in midwinter—the tool was discovered fractured clear across from cutting edge to back, due undoubtedly to a combination of stresses imposed by the action of the clamping bolts and by the change in temperature. It is my recollection that provision was made to obviate this trouble with later tools of the same character by modifying the clamping method.

The other occurrence was not so easily explained, although quite understandable: We had two valuable 12-in. verniers on the job in constant use and never out of sight except when returned to the toolroom at night. One morning we discovered that the vernier plate from one of these tools was missing, and without doubt it was borrowed by somebody to complete a vernier he had under construction for his private equipment of measuring appliances. Never having had time nor inclination to make one of these precision calipers myself, I felt cleared of any suspicion which might otherwise have fallen in my direction, and I always believed the other members of the crew to be as innocent as myself. I remember that the department-foreman was somewhat annoyed by the transaction, and I am still wondering if he ever located the missing vernier plate.

One of these shredding machines, as now made, was exhibited in operation at the exposition, motor driven and up to date in every respect. A detail of one of the rolls described is shown herewith, dimensions being approximate only.

It will probably occur to many inquiring minds to ask why such precision is required in machine parts used merely in the process of stripping up a soft, plastic material where accuracy of product would seem to be of little importance and if of any importance would seem to be equally unattainable because of the nature of the material itself and of subsequent processes through which it may be passed. We, as machine designers, are prone to believe that as soon as we depart from the working of hard materials like metals, hard rubber and possibly a few similar substances including perhaps certain articles made of wood, any special degree of accuracy is practically impossible as a commercial attainment and if really feasible would be of no special advantage. As a matter of fact there are many materials like paper, leather, fabrics of one kind or another, articles produced from paper pulp and other plastic substances where accuracy of product is not only required, thus making accurate manufacturing equipment essential, but where, without this accuracy in the process, the present great speed of output would be entirely impossible even though the product itself might in cases pass inspection so far as character of fabrication is concerned.

There are instances in considerable number where without accurate contacting surfaces materials will not feed properly through the machine; where the quantity passing under the operating mechanism during a given cycle will be either insufficient or too liberal in amount; where the contact surfaces themselves will not be kept properly cleaned to continue their work as they should. These are some of the factors having an important bearing upon the design and construction of a large class of machinery including among other groups food-preparing apparatus.

The manufacturer of food products has to consider a number of things which do not enter into the experience of the producers of a vast number of other articles. His goods must be absolutely clean if he is to hold his market indefinitely; they must be produced in enormous quantities if he is to interest big distributors of such products; each package turned out must be fully up to weight or he will run foul of the food laws; and yet he must not regularly exceed the specified weight in any appreciable degree, for if he does so, his profits will disappear.

Anyone who has had the opportunity to inspect some of our great establishments engaged in this and kindred industries cannot fail to have been impressed by the extent to which automatic weighing apparatus has been installed in such places to provide a positive safeguard against the possibility of a single food container being shipped from the factory either under or over weight by even a minute fraction of an ounce. For this reason alone, if for no other, accuracy in food-manufacturing machines thoroughly justifies itself.

Readers of these columns have already had the opportunity of examining illustrations of the "Iron Chink" made by the Smith Canneries Machine Co., of Seattle,

Wash., for dressing salmon at a previously unheard-of-rate of speed, displacing in the case of each machine dozens of hand laborers formerly employed exclusively in this process. Articles have also appeared showing the accuracy of the methods utilized by that firm in building this automatic machine. It has to be made properly in order to run at all; and it has to be built very accurately in order to operate at the requisite rate of speed for making it an economic factor in canning establishments as compared with the cheap, unskilled, but nevertheless rapid, hand labor universally employed in the past for dressing and packing fish.

One of these machines which has now been built for several years was exhibited at San Francisco, where probably for the first time a few million people learned that it is no longer necessary to dress and pack by old-fashioned hand methods the several hundred millions of pounds of salmon annually prepared for market in the great Coast fisheries.

This company builds other machinery for canneries and similar establishments, one of these an automatic weighing machine in which filled cans as they pass are switched to one side or other of the main line of movement if they are either overloaded or underweight in the slightest degree. The deviation from standard weight may then be rectified and the cans passed along with the bulk of containers which have already gone through the machine and stood the test of accuracy in weight.

Still another important line of apparatus of allied character produced by this firm and exhibited at the Panama-Pacific Exposition was candy making machines of various types; one such is for the manufacture of sugar peppermints. In operation, several hundred, possibly a thousand or more, peppermints feed slowly along the apron on the top of the machine, the sugar mixture of the right degree of consistency being ejected automatically from the receptacles at the head of the machine. The candy mixture once made, charged with the desired flavoring ingredients and placed in the receiving tanks is automatically maintained at proper consistency, is forced at the right intervals and with the proper amount of weight and of the desired size upon the traveling work table. During its passage along the machine to the point of discharge into packages it attains the requisite degree of hardness, and all this without the intervention of the attendant or the touch of his hands.

Restaurant Machinery

Another interesting and useful machine for automatically preparing good things to eat was a roasting device used by a restaurant on the Zone. I do not know who installed it. I do know that its work of helping to prepare properly cooked food for thousands of hungry visitors was eminently satisfactory. As there operated, it constituted a modernized extension of the old roasting spit which our early ancestors slowly revolved with its burden of flesh, fish or fowl before the great open fires of long ago.

In the new form the apparatus embodies something of the principle underlying some of our modern hardening furnaces in that the material to be subjected to the action of the heat is passed slowly along the zone of high temperature and at the same time rotated so that every portion of the object is acted upon uniformly. Several roasts, whether chicken, beef, mutton or other, are cooked simultaneously, and the output of this installation as required by restaurant patrons on the Zone was something astonishing to persons not accustomed to seeing rations provided for an army. The attendant told me during the closing days of the exposition that during the ten months of the show he had roasted on the machine over fifty thousand chickens, and as for beef and other roasts, as he expressed it, "the Lord only knew how many of these had been cooked on the apparatus."

This article has done little more than touch upon a few of the many mechanical devices which, as operated at the exposition, seem of unusual interest to the designer as indicating a marked tendency toward covering in the near future the entire field of food products with the machine process. While, as pointed out, the earlier developments in this direction are well known, there are in the field large numbers of new machines with which comparatively few people have had the chance to familiarize themselves. And it would appear that the opening here for the trained designer is a broad one, with almost unlimited opportunity for original work in developing ways and means of handling and preparing foodstuffs for shipment and consumption.

There are at present on the market, and examples were exhibited at San Francisco, full outfits of mechanical apparatus for sorting and grading oranges and other fruits; for cleaning and packing raisins; for sorting olives, crushing them, refining the oil and so on. A great deal of this equipment has been developed in California and is to be seen in no other section of the country.

Evolution of Repeating Small Arms and Ammunition

By Robert F. Mitchell

Away back in the fifties, or earlier, came what was called the "pepper box" pistol put on the market by Col. Samuel Colt, of Hartford, Conn. It was loaded from the muzzle with powder, wad and a round bullet. A good many '49-ers used it in their rush to California for gold. It was not a very reliable weapon, as there was almost no barrel, the charge coming out of the cylinder. There was not much force to the charge when it was fired.

The story was current when I was in Springfield that Colonel Colt got his idea of the weapon from one he saw in the Tower of London. He improved it and started making it, and from that was evolved the modern Colt revolver. In 1860 came along the first revolver that used fixed ammunition, made by Smith & Wesson, of Springfield, Mass. They first produced them at the Market St. shop and then had some ten thousand made at Rock Falls, Conn.

In 1861 they built a new factory on Stockbridge St. I went to work for them in June, 1861, in their new shop. I remember that they used the upper floor for making their 0.22 cartridges, and as it was a new thing to have the powder, bullet and fulminate all in one small copper shell, they were not perfect, and a great many misfires resulted.

Some progressive people in Bridgeport saw the possibilities of a business and started making the cartridges. In a short time Smith & Wesson sold out that part of

their business, but continued making their revolvers. While I was there they were making 2,000 of the 0.22 size per month, and 1,000 to 1,200 of the 0.32 caliber.

From the hinge barrel came the spider which ejected all the cartridge shells at once. It was invented by a man named Rodier, a French Canadian. After this appeared the automatic, which is not a revolver at all, as it ejects the empty shell by means of the gas which comes from the firing of the cartridge.

Evolution of the Small Arm

The evolution of the gun was as follows: First came the match lock; second, the flint lock; third, the skin cartridge fired by a hat cap on a nipple of the gun; fourth, the thin metal rim fire; fifth, the folded head with a rim reinforced by an inside and outside cup. Then came the center fire, with a small primer in the center of the head.

Along in the years between 1850 and 1860 a man by the name of Rollin White invented the Smith & Wesson revolver. The story I heard during the two years I worked in their factory was this: "Rollin White was on the river bank one Sunday trying his invention when along came Dan Wesson. He stopped, looked the gun over, tried it, and was so taken with it that the two came to terms."

Wesson was to give White $1,000 cash and 25c. a pistol during the life of the patent. White was to defend his patent, which he had to do in a number of cases. One suit lasted almost three years, but he finally won out in all of them. There were three shops making his pistol, and all a direct infringement on his patent.

Wesson hunted up Smith and they formed a partnership, Smith furnishing $20,000. Rollin White was a lame man. I remember him well, as he was experimenting on his pistol in the next vise to mine. One of the cartridges went off and the ball passed very near me and hit the wall beyond. After that he went into the cellar to do his experimenting. That little incident fully impressed Rollin White and his invention on my mind.

Previous to 1861 White invented what was known as the "volcanic pistol," which was the nucleus of the Winchester gun. It was about a foot long, the barrel and magazine being one piece of steel. The ammunition consisted of a pointed bullet about one-half inch long. It was hollow for about two thirds of its length and filled with powder. A wad containing the fulminate was crimped into the bullet, and when fired the bullets would go possibly 500 ft., while others would go perhaps 10 or 20 ft.

The pistol was a failure on account of the poor ammunition; but the principle was there and was finally improved into what was known as the Henry rifle, worked out by Tyler Henry. Gov. Oliver F. Winchester then bought out Henry's patents and formed the Winchester Repeating Arms Co., which has prospered so that its guns and ammunition are known the world over.

I have been connected in one way and another with the gun and ammunition business ever since I was 16 years old, so have had a chance to know and observe a great deal about both. I went to work for the Winchester Repeating Arms Co. in the year 1871 and shortly afterward went into the cartridge room, where I made the dies and punches for the manufacture of what is called the 0.44 flat-rim fire cartridge. We made 20,000,000 for the Turks, who previously had purchased some 30,000 or more rifles for the use of their troops and police in Constantinople.

George Stetson was the cartridge man in charge at that time. There were only two other places where they made rim fire cartridges—the Union Metallic Cartridge Co., of Bridgeport, and one in Springfield, Mass., owned by a man named Leete.

Small Copper-Pipe Bending Forms

By E. V. Allen

Bending forms for the purpose of giving copper pipe the right shape for use as oil or gasoline feed pipes on Henderson motorcycles are shown in Figs. 1 and 2. The pipes are ¼ in. outside diameter, and soft enough to be bent by hand. In the forms shown in Fig. 1 the pipe ends are placed in the sockets indicated at *A* and *B*. and then the pipe, which has previously been cut to correct length, is simply pressed against the forms with the fingers.

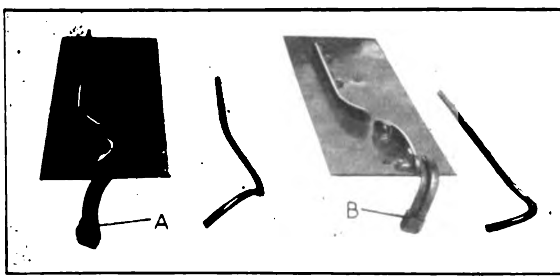


FIG. 1. FORMS FOR BENDING OIL AND GASOLINE PIPES

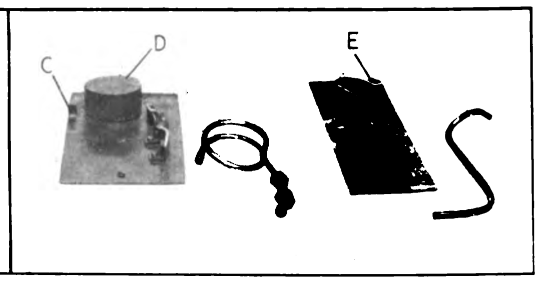

FIG. 2. TWO OTHER PIPE-BENDING FORMS

In Fig. 2 the pipe is first started with the end just between the block *C* and the center plug *D*. It is then coiled around the plug once and on the second turn is made to follow the form at the right. After the pipe is removed from the form the coil is pulled apart slightly, as shown. The pipe at the right is started at *E* and then shaped as are the others.

While these pipes are soft and easily bent, forms like those shown are necessary to prevent kinks, careless bending or other trouble. Made in this way, the assemblers have little trouble in making a good-looking job without the necessity of tinkering on the work after the bend is made.

Making 1-Lb. Cartridge Cases--I*

By Robert Mawson

SYNOPSIS In this article are described in detail the tools and methods used in manufacturing the 1-lb. cartridge case. Owing to the close limits called for on the shell, some difficulties in tooling were met with. The tools described are producing a shell to the desired requirements. The various types of machines and the rate of production are also included.

The manufacture of the 1-lb. cartridge case demands many interesting punch press operations. This will be apparent when the close limits allowed on the shell are noticed. The New York & Hagerstown Metal Stamping

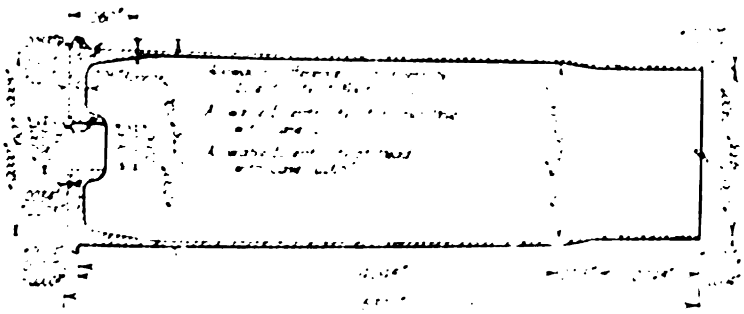

FIG. 1. DETAILS OF 1-LB. CARTRIDGE CASE

Co., Hagerstown, Md., is producing a high-grade case, and the tools and methods employed are here described.

In Fig. 1 is shown a detailed illustration of the cartridge case. The various stages through which the element progresses from the punched blank to the com-

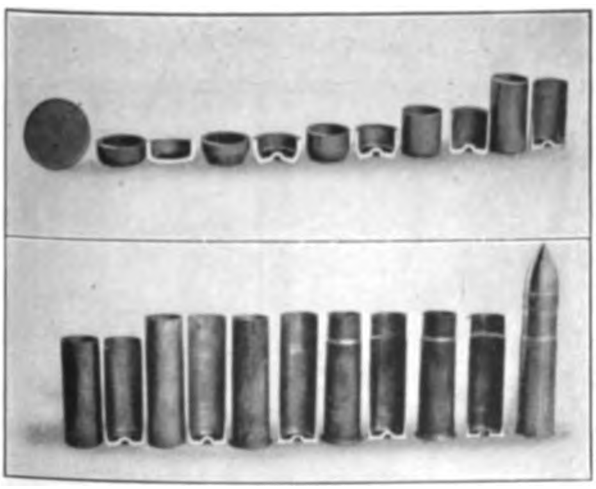

FIG. 2. VARIOUS STAGES OF 1-LB. CASE FROM BLANK TO FINISHED PART

pleted cartridge case are illustrated in Fig. 2. For each of these stages a sample has been cut, so that the work performed may be observed. The chemical analysis of the brass used for making the cases is: Copper, 70 per cent.; zinc, 30 per cent., with a variation of 1 per cent. either way and an allowance of ½ per cent. for impurities. The physical qualities are 48,000 to 54,000 lb. tensile at the mouth, 58 per cent. minimum local elongation. At the head the tensile strength should be 60,000 lb. minimum, and no local elongation is specified at this point. Under the head the tensile strength should be 58,000 lb. minimum, and no local elongation is specified. The specifications called for in manufacturing the cartridge cases are as follows:

TABLE OF SEQUENCE OF OPERATIONS

1. Blank	13. Trim to length	21. Machine to length
2. Cup	14. Anneal and pickle	22. Burr inside of primer hole
3. Anneal and pickle	15. Fifth draw	23. Finish-machine primer hole and form recess
4. Indent	16. Trim to length	24. Wash
5. Anneal and pickle	17. Head	25. Final inspection
6. First draw	18. Anneal open end and wash	26. Stamp
7. Anneal and pickle	19. Form taper	27. Pack ready for shipping
8. Second draw	20. Face and finish-machine flange and rough out primer hole	
9. Anneal and pickle		
10. Third draw		
11. Anneal and pickle		
12. Fourth draw		

1. The cases must be cold drawn from brass of the proper quality.

2. The curvature at the neck shall conform to that of the standard gun chambers shown on the drawings, within manufacturing limits.

3. Ten from each lot of 5,000 shall be selected by the inspector to be proved.

4. The proof shall be the firing of each of the selected cartridge cases once with service charge and shell. Two of the fired cases shall then be selected by the inspector; and from each of them three additional service rounds shall be fired without re-forming, but the forward end of the cylindrical part of the neck may be contracted sufficiently to grip the shell at each reloading.

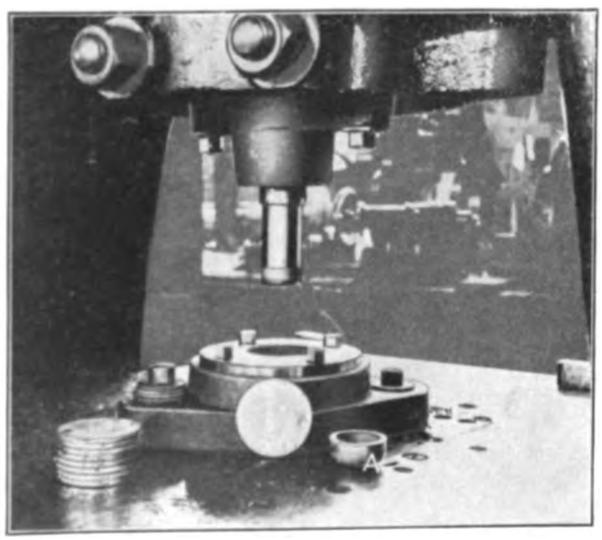

FIG. 3. CUPPING PUNCH AND DIE FOR FIRST BLANKING OPERATION

5. The proof cases of accepted lots may be incorporated in the regular lots, provided they are re-formed and again pass inspection.

6. No cases must show signs of weakness or excessive hardness.

The blanks from which the cases are made are purchased and measure 2⅞ in. in diameter and 0.20 in. thick.

The blanks are cupped with the punch and die shown in Fig. 3. For this operation the blank is placed in the die; and when the punch is fed down with the machine, the part is formed to the contour *A*. A diagrammatical view of the operation is given in Fig. 4.

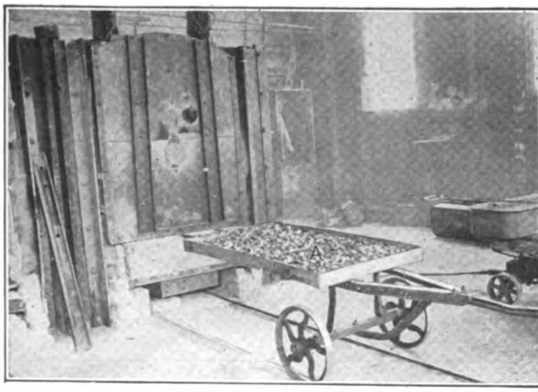

FIG. 9. GAS-HEATED ANNEALING OVENS

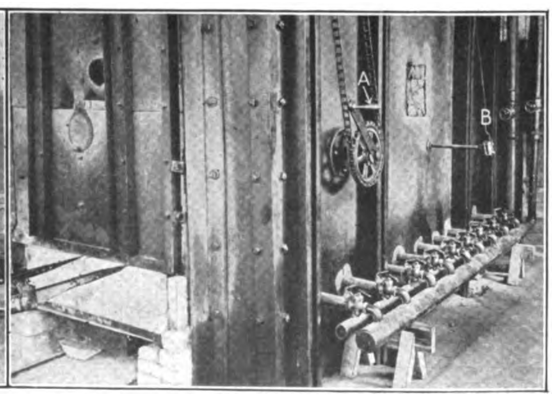

FIG. 10. SIDE VIEW OF ANNEALING OVEN

A detail of the punch and die is seen in Fig. 5, the bolster in Fig. 6, the retainer plate in Fig. 7 and the punch holder, which is used for the cupping operation, in Fig. 8.

The shells are annealed in the gas-heated oven illustrated in Fig. 9. The parts are placed on the tray *A* and conveyed by the truck shown. The tray is then slid into the oven, the average temperature of which is approximately 1,380 deg. F. The parts are allowed to remain in the oven 30 min.

In Fig. 10 is shown a side view of the oven, and the manner in which the gas is fed may be seen. It will be observed that the arrangement is fitted with nine branches, which are fastened into the main supply pipe. These branch pipes convey the gas and distribute it so that a sheet of flame may be obtained under the tray

holding the parts to be annealed. The handle *A*, operating through the sprocket and chain shown, is used for opening the furnace door. The temperature of the furnace is taken by a pyrometer through the lead wire *B*.

After annealing, the parts are conveyed to the pickling tanks, Fig. 11, and washed in "Edis" compound, to remove the scale. The parts are then transferred to the punch and die, Fig. 12, to be indented. The cupped shell is placed in the die *A*. The punch *B*, fed down with the machine, forms the indentation. The operation is shown in diagrammatical form in Fig. 13.

The retainer plate, Fig. 7, the punch holder, Fig. 8, the punch, Fig. 14, the center section, Fig. 15, the die, Fig. 16, and the bolster, Fig. 17, are used for the indenting operation.

The parts are then annealed and pickled in a similar manner to that described for the previous operation. After the pickling they are returned to the machine illustrated in Fig. 18, and the first drawing operation occurs. The part is placed in the die *A*, and the punch *B* is fed down, performing the first drawing operation. One

of the parts before drawing is shown at *C*; and after being drawn, at *D*. The operation may be seen in diagrammatical form in Fig. 19.

The punch holder, Fig. 8, the punch, Fig. 20, the die, Fig. 21, the bolster, Fig. 22, and the retainer plate, Fig.

FIG. 35. FOURTH AND FIFTH DRAWING OPERATIONS

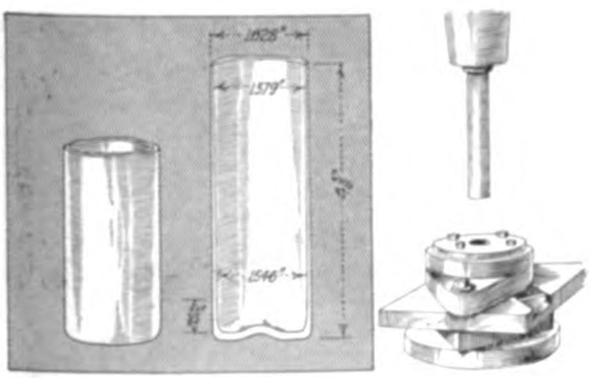

FIG. 36. OPERATION 12. FOURTH DRAWING
Machine Used—Bliss 15-in. stroke press.
Production—[illegible] per hr.
References—Figs. 8, 22, 29, 35, 37, 38 and 39.

The punch holder, Fig. 8, the bolster, Fig. 22, the stripper, Fig. 29, the punch, Fig. 32, the die, Fig. 33, and the retainer plate, Fig. 34, are used for the third drawing operation.

The parts are again annealed and pickled in the manner described and are then conveyed to the machine shown in Fig. 35 for the fourth and fifth drawing operations. The punch *A* and the die *B* are used for the fourth drawing operation, which gives the form shown at *C*. This operation is also shown in a diagrammatical view in Fig. 36. The punch holder, Fig. 8, the bolster Fig. 22, the stripper, Fig. 29, the punch, Fig. 37, the die, Fig. 38, and the retainer plate, Fig. 39, aid in this drawing operation.

The case is next taken to the special lathe, Fig. 40, and the open end trimmed so that the overall length is 4½ in. The case is gripped with the wooden tongs *A* and slipped into the chuck *B* against a stop surface.

The handle *C* is drawn forward, actuating the jaws of the chuck so that they grip the case securely. The parting tool *D* is fed against the revolving case, and the end is trimmed to the correct length.

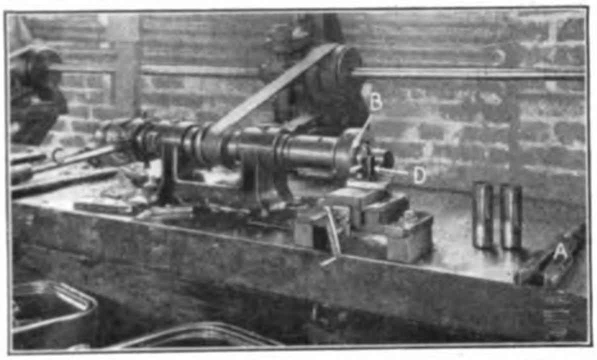

FIG. 40. TRIMMING END OF SHELL

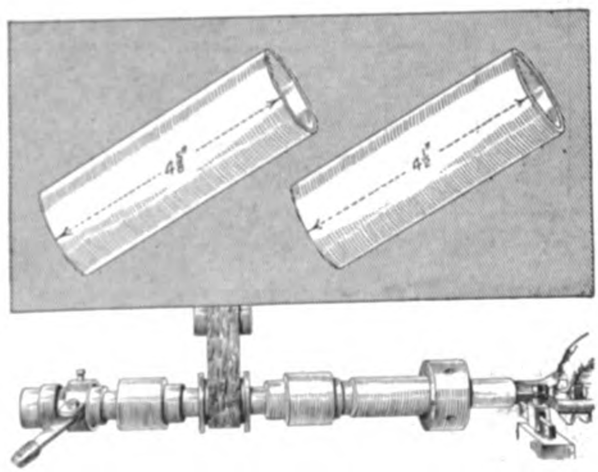

FIG. 41. OPERATION 13: TRIMMING TO LENGTH
Machine Used—Special lathe.
Special Tools—Lathe, chuck, wooden tongs and parting tool.
Production—200 per hr.
Reference—Fig. 40.

The handle is pushed back, thus releasing the chuck, and with the aid of the tongs the case is removed from the machine. This operation is shown in diagrammatical form in Fig. 41. The case is transferred to the oven, annealed and afterward pickled in a manner similar to that previously described.

The case is now ready for the fifth and last drawing operation, which is performed on the machine that was used for the fourth draw, Fig. 35. The punch *E*, being forced down, draws out the shell, which has been placed in the die *D*, to the contour *F*. This drawing operation is shown in diagrammatical form in Fig. 41-A. The punch holder, Fig. 8, the bolster, Fig. 22, the stripper, Fig. 29,

the punch, Fig. 42, the die, Fig. 43, and the retainer plate, Fig. 44, are used for this last drawing operation.

The shell is then taken to the lathe, Fig. 40, which has the stop in the chuck set so that the distance from

the end of the shell to the tool is 5½ in. The shell is placed in the chuck and is trimmed in a manner similar to that previously described.

(To be continued)

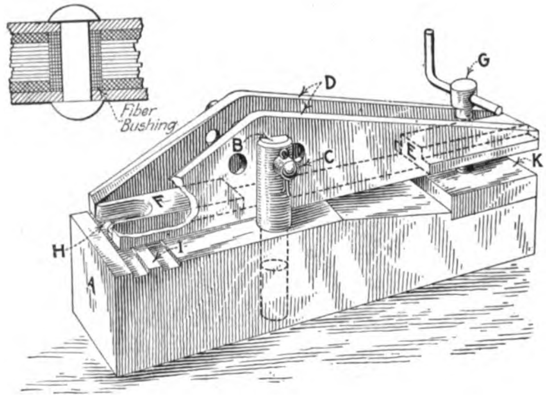
Riveting Insulated Laminations

By Jan Spaander

Insulating materials play an important part in many industries, but fibers, bakelites and condensites are often difficult to handle, especially when riveting several layers of thin punchings between a layer of fiber and iron on each side, as illustrated. The rivet passes through a fiber bushing, and when riveted it is apt to bend slightly and burst the bushing. The defective work can only be discovered by testing the finished product.

A successful riveting jig is shown in the sketch. The cast-iron base plate *A* carries the two steel bearing pins *B*. Through these bearings a pin *C* forms the fulcrum of a yoke *D*, consisting of two vertical steel plates that are clamped together by the plates *E* and *F*. The plate *F* is cut out at the nose of the jig to allow passage to the rivet.

The plate *E* is the nut for the screw *G*, with which the nose can be made to press the piece to be riveted between the surfaces *H* and *I*. The yoke has different fulcrum holes to suit different jobs. The sides of the slot in the plate *F* and the nose of the yoke *D* are scooped



RIVETING INSULATED LAMINATED PARTS

out to give easy access to the hammer. To allow a quicker opening of the jaw, a loose plate *K* is put under the screw.

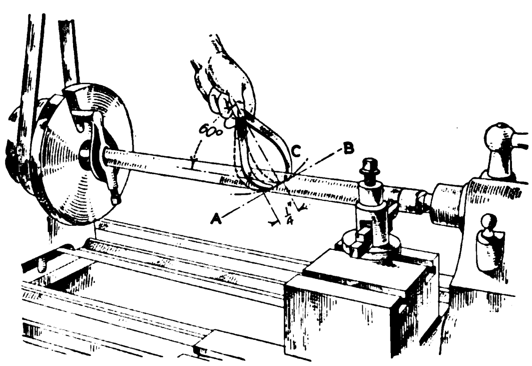
The bushing is made slightly long; and when the pressure of the jig forces the soft fiber of the bushing against the rivet, this has to stand straight and take the hammering.

Calipering Running Work

By M. Jacker

Calipering can be readily done while the lathe is running by the method herewith described for filing and polishing to within 0.0005 in. (or one-half a thousandth) of size.

Make a spot at the end of the work to suit the micrometer measurement, then start the lathe on a filing speed. While the lathe is running, set the calipers by this spot, just so that you can hardly feel



CALIPERING RUNNING WORK

them making contact when held at about 60 deg. and swung ⅛ in. on each side of the center line, as shown. Care must be taken that the caliper leg *C*, or the one farther from you, does not get to the left of the other leg, or it will get caught on the work. Both points of the caliper must be on a line, as *AB*, square with the shaft.

Lubricating Oils and Cutting Compounds for Shop Use*

By W. Rockwood Conover†

SYNOPSIS--*Wastage of oils and cutting compounds through inexpert buying and careless use is common in machine shops. The principles that should govern selections, tests that should control quality and methods that should give satisfactory use are all outlined. The cheapest oil or compound is often the most expensive.*

One of the subjects that enlist the attention of the manufacturer is that of lubricating oils and cutting compounds. The manufacturing plant that does not include among its departments a chemical testing laboratory where proper tests of lubricants can be made and values accurately determined often depends upon the judgment of its superintendent or department heads, with the too frequent result that either a too high price is paid for oils or else quality is sacrificed in a mistaken idea that, by employing cheap oils, money is being saved. There is scarcely any other subject connected with machine-tool operation on which there is such diversified and contradictory opinion and judgment as that of the lubrication of machine-bearing surfaces and the lubricating of cutting tools.

Often the superintendent or foreman of a department in selecting oils depends upon the judgment of the operator, which is apt to be based by years of following some previously established rule or practice taught in the early days of learning his trade. Many of the old theories and practices have become obsolete and have been shown under the light of modern shop experience to be not only expensive, but not of equal value to the practices established in recent years.

Lubricating Oils for Machinery

The preserving and maintaining of bearing surfaces of machinery and minimizing of friction are of prime importance and should have preference over all other considerations in the purchase of lubricating oils. In addition to chemical tests practical tests should be employed to determine satisfactorily the wearing quality and value of lubricants. To accept the opinion of individuals or dealers may as often prove expensive as otherwise. A reduced oil account is not economy if the ledger shows greatly multiplied upkeep and repair charges on machine tools at the end of the year and the factor of depreciation much increased. There is a wide latitude in the degree of viscosity of lubricating fluids between lubricants having a low specific gravity and lubricants having too much body; between pure mineral oils and those containing a high percentage of animal fats that tend to acidity and produce a corrosive effect, however modified, on bearing surfaces.

The small manufacturer not in a position to employ chemical analysis should at least determine by practical tests the lubricating value of given oils on the specific work on which he desires to use them in his own factory. The importance and advantage of such tests in large establishments are equally obvious and not to be questioned, but there the conditions are essentially better and the facilities multiplied. The necessity for accurate data is also proportionately greater.

An oil purchased at a comparatively low cost may be good; it may answer the purpose, but it may be neither economical nor wise to use it in the long run. On the other hand, the axiom "The best is the cheapest" is not always a true one. Certain oils are adapted to the lubrication of shaft bearings, the bearings of shop motors and high-speed power-transmission machinery, but they are not adapted to the lubrication of the bearing surfaces of large boring mills and lathes, of millers and planers having heavy friction load. An oil of lighter body or less viscosity can be selected for the former than is practicable for the latter class of machinery. Conditions must be carefully studied—speeds, pressure, temperatures, friction load, etc.—and careful tests made, if the manufacturer would wisely and economically choose the grade or kind of lubricants adapted to his work. An error in judgment in the grade of oils for costly machine tools may necessitate repairs that neutralize the saving in purchase price for many months. With the indifferent manufacturer oil is oil, and through lack of proper attention to this important feature of factory expense the careless operative is as likely as not to use cylinder oil on all the smaller working engine parts or high-grade machine oil on line shaft bearings; and the practice is likely to be continued unobserved until serious trouble or loss results.

For the bearing surfaces of large machine tools an oil free from animal fats, of increased specific gravity and of much greater viscosity than oils designed for light high-speed machinery should be selected. This sort of lubricant will give increased wearing quality where speeds are comparatively slow and the friction loads more or less heavy. Such machine oils can be purchased at prices ranging from 14 to 20c. per gallon. With these oils there will be no increase in temperatures, and the bearing surfaces will keep in excellent condition. For babbitted surfaces on light machinery cheaper oils will serve.

Some manufacturers select an inexpensive mineral oil, costing 12c. or less per gallon, for general lubrication of machine tools, shafting, shop motors, etc. The economy of this practice is doubtful under conditions of heavy friction load or high speed, when the proper maintenance of shop machinery and of machine tools is considered and the expense of such upkeep for the year computed. An oil costing at least 30 or 40 per cent. more than the just mentioned figure will give far more satisfactory results and be found more economical in the long run, both from the standpoint of consumption and that of keeping the tools in good condition.

For lubricating the bearings of cranes of high-tonnage capacity and on some other classes of heavy machinery operated at low speed, where the friction load is not too

*Prepared for the author's forthcoming book on "Industrial Economics."

†Factory economist, General Electric Co.

great to permit their use, one of the cylinder-oil stocks at a cost not exceeding 15 or 16c. per gallon can be chosen to advantage. These oils are also suitable for lubricating rubber mills, heavy rolls, cylinders, etc.

In running experimental tests and commercial tests on electrical or other machinery preparatory to shipment a good quality of mineral oil costing from 10 to 12c. per gallon should be employed as a substitute for the higher-priced oils preferred in the permanent operation of the machines. One of the reasons for this substitution is the fact that in these preliminary tests the facilities for handling the oil and preventing leakage are not, as a rule, as complete as when the machines are installed in their permanent location, and there is consequently an increased percentage of consumption and waste. It has been found by experiment that temperatures, even where machines are operated under high speed during the process of testing, are not perceptibly increased by the use of the cheaper oil. In all such cases, however, it is advisable to make careful tests on the specific work for which the lubricant is required, to determine any difference in temperature or friction load, before a permanent change is made.

Cutting Oils and Compounds

Regarding the subject of cutting oils and cutting compounds there is wide diversity of opinion. Not a few manufacturers of the old school still hold the belief that pure lard oil is the cheapest and most satisfactory cutting lubricant for most classes of work in the long run. In the majority of cases this opinion is the result of clinging to old theories and of aversion to inaugurating new practices; or if based on actual tests and experiments, the tests have not been conducted on a practical basis. Were we to grant the correctness of judgment of these manufacturers in so far as the wearing quality of oil is concerned, we have still the factors of cutter grinding and the keeping of tools cool to consider. It has been demonstrated by practice that on certain classes of work and under certain conditions a compound into which water enters largely as a component part is not only cheaper in cost, but superior to pure oil in cooling properties.

On account of the number and variety of cutting lubricants on the market careful chemical analyses and practical tests should always be made by the manufacturer before purchasing. Nearly all compounds contain a certain percentage of free fatty acid and consequently are acid in their reaction, and nearly all have a more or less detergent action on metal surfaces covered with oils. Choice should be made of those compounds which are least acid and which exert the least corrosive influence on metal surfaces. This is especially important in the case of multiple-spindle machines and all machines where the work is in close proximity to the bearing heads, as under these conditions the oil is likely to become washed from the bearings and the expense of machine-tool repairs, in consequence, to be materially increased.

The initial cost of any cutting lubricant is relatively unimportant. What the consumer needs to know primarily is the action of the lubricant on the point of cutting tools in reference to absorbing and neutralizing heat generated in cutting, its lubricating properties, its wearing quality, its specific gravity, flash point, percentage of free fatty acid and in the case of water compounds its ability to form a perfect emulsion and remain in a proper state of solution. The factor of retaining metal dust in suspension must also not be overlooked. Some compounds run dirty continually until entirely consumed, holding minute particles of metal dust in suspension until the compound becomes thoroughly charged with this foreign matter. This condition tends to increase friction at the point of the cutting tool and to raise temperatures abnormally, thereby reducing in some degree the cutting power. Lastly, the intial cost is important, but only relatively so. An oil of high market price may wear sufficiently longer than the cheaper grades to show a lower running cost per hour, and this is frequently true. It is one of the strongest arguments in favor of the use of pure lard oil or a high-grade mixture of lard and mineral oil.

When the manufacturer is about to purchase any of the cheaper oils or water compounds, he should insist upon being furnished by the refiner or dealer with running cost per hour, or consumption, on various classes of work, for comparison with the cost of lubricants he has previously been using. If these data cannot be obtained from the dealer, the manufacturer should conduct accurate and careful tests in his own shop in order to determine the relative economy of lubricants offered him. Without these precautions he can form no intelligent judgment in the matter and is as likely to be deceived as otherwise.

These comparative tests must include the cost of repairs to machine tools and many other items of information, as indicated in the paragraph on testing, in order to obtain data of sufficient value to render a decision as to purchase safe and correct. Even under such exhaustive analysis any fluctuation in the cost of maintenance of machine tools may be due to the character of the work performed and the strength of the tool itself rather than to the use of a different lubricant. For this reason it will readily be acknowledged that the manufacturer must, to some extent at least, base his decisions on broad judgment and experience, his habit of observation and his insight into the conduct of processes in his shop. It is not exceeding the limit of truth, however, to state that a very large percentage of the consumers of cutting oils and lubricants do not know with definite certainty the actual conditions with reference to economical consumption of these materials within their shops, and often too much dependence is placed on the statements of dealers or on the judgment and opinion of the tool operator.

Testing Cutting Lubricants

In making practical tests of cutting lubricants it is desirable to select a piece of work on which the machine can be run for at least one week, and a much longer period is preferable. The oil cups should have attention to see that there is a free flow of oil to the bearings. The tank should be thoroughly cleaned of the previous lubricant, and all bearing surfaces, turret heads and slides should be cleaned before the machine is loaded for test. It is not sufficient to allow the lubricant to flow onto the top or side of the tool. The feed pipe should be so arranged that a full, strong stream will be carried directly to the point of the tool and to the surface being cut, in order that the tools and work may be properly cooled. Of equal importance is the manner in which the tools are ground. A good compound has often been condemned through ignorance of these two essentials—the

adjusting of feed pipes for proper flow and the grinding of tools at the proper angle for greatest efficiency on the surfaces to be cut. Grinding the cutting tool at a wrong angle not only results in increased heating and loss of cutting power, but is frequently the cause of bad work as well. To this must be added the increased cost of frequent regrinding and the loss through delay and stoppage of productive work.

When the machine is loaded with compound and the test started, it is necessary that the proportion of stock or stock solution and water be maintained uniform throughout. Otherwise, the running cost per hour or cost for a given quantity of work cannot be satisfactorily ascertained, as the quality of the work will not be uniformly good. With all cutting lubricants into which water enters as one of the component parts the factor of evaporation is a serious one, and it is necessary, after the first day's run, to add more water, in greater or lesser amount, each succeeding day to hold the proportions constant. The degree of dilution called for in the manufacturer's or dealer's specifications should be maintained throughout the test. Without this care the operator will after a few days be running a mixture fully as expensive per hour's run or per piece as lard or other oils. It may be even more expensive.

In conducting comparative tests the following data should be carefully kept: Total running time, time spent grinding tools, time spent on repairs or other delays, actual operating time, condition of tools at commencement, depreciation of tools, speed and feed, number of pieces finished, quality or character of work done, number of gallons of compound in reservoir at start, number of gallons of compound in reservoir at finish.

With preliminary tests of this kind the cost per running hour and ratio of economy and advantage between different kinds of cutting compounds sold on the market, or between a cutting compound and a cutting oil, may be safely and satisfactorily determined. In the case of lard oil or mineral oil or a mixture of both the oil should be reclaimed from the chips and this amount deducted from the quantity with which the machine was originally loaded, the cost of reclaiming being considered in the final estimate.

After the choice of a cutting compound has been determined upon, the bearings of the machines should be opened at reasonable intervals and conditions noted; and careful inspection should be made of slides and all other wearing surfaces with which the lubricant has come in contact. Machines operated with any of the various water cutting compounds should be inspected and cleaned with greater frequency than those loaded with oil for reasons previously indicated in the paragraph relating to fatty acids and their tendency to corrode or wash oil from bearing surfaces. The cost of machine repairs should also receive attention and a comparison be made, after a reasonable length of time, with previous periods, taking into consideration the number of hours the tools are operated and the character of the work or burden placed upon the machine.

In addition to the reduced cost per running hour effected by the use of proper cutting compounds the factor of speed is worthy of consideration. It has been demonstrated that, with the right kind of lubricant, the cutting speed can in many instances be increased from 10 to 15 per cent. As productive output per machine is of prime importance, particularly in the factory where tool equipment and space are limited, the securing of this advantage is desirable.

There are certain classes of work in the shop, such as milling large-sized keyseats, turning, tapping, threading and milling operations on steel containing a high percentage of carbon, where the work involved is unusually hard, in which the use of pure lard oil is wise. In this case it is well to use either a grade known as "prime lard oil" or one known as "off-prime lard oil." The amount of fatty acid in the former does not usually exceed 2 per cent., and in the latter the percentage is only slightly greater. The advantage of employing these grades, where pure lard oil is indicated, will be apparent, as they exert little or no detergent effect on machine tools, greater speeds are possible than can be secured with cheaper grades of oil, and they give most excellent service from any standpoint. The lower grades, known as "extra No. 1 lard oil" and "No. 1 lard oil," are not recommended. The former may contain as high as 10 per cent. of fatty acid, and in the latter this element may reach 20 per cent., which makes it undesirable as a cutting fluid.

Lard Oil and Lard-Oil Mixtures

A large percentage of the heavy-duty work in most shops can be done to advantage with mixtures of lard oil and mineral oil or a good quality of mineral oil.

For automatics and for general screw-machine work on copper and steel where tapping or threading constitutes a part of the operations performed a lubricant consisting of equal parts of lard oil and mineral oil undoubtedly gives the best service. The mineral oil should be of fair quality, and the cost of the mixture should not exceed 35 to 40c. per gallon, according to market prices on lard oil. This makes a good lubricant of excellent body and sufficiently viscous to form a continuous and comparatively thick film on the point of the cutting tool. The tools stand up well and require less grinding than is the case when lighter-bodied oils are employed.

This formula for cutting oil, designed to do the most difficult operations of tapping and threading copper and steel in automatics and turret machines and other heavy-duty work on steel, is more satisfactory and more economical in consumption than the so-called mineral lard oils and screw-cutting oils generally offered to the manufacturer. The mineral lard oils and screw-cutting oils at prices ranging from 24 to 35c. per gallon must necessarily contain an increased amount of mineral oils or low-grade petroleum distillates, in order to yield the oil manufacturer or dealer a profit. If the consumer mixes his own lubricant, he is enabled to obtain a full-strength, equal-part solution of the two oils at a figure as low as, or lower than, he is compelled to pay for the so-called special cutting oils on the market. And this equal-part mixture has greater wearing durability and keeps the tools in better condition.

Any statements made to the effect that the mineralized lard oils or screw-cutting oils can be employed as a lubricant base and thinned down in the same manner in which prime lard oil or off-prime lard oil is capable of being reduced should receive careful and serious consideration before purchases are made.

From an economical standpoint the consumer will find it wise to make his own mixtures. By doing this he has accurate knowledge of the quality of the lubricants em-

ployed on his machine tools, the ingredients composing each formula are fully within his control, the machine-tool equipment is better conserved, and a saving of at least 25 per cent. in initial cost should be the result.

In general, for the purposes of drilling, turning, shaping and cutting off of steel and copper and also for all operations on brass in automatics, semiautomatics and multiple-spindle turret machines a good quality of mineral oil not exceeding 12 to 15c. per gallon in cost gives excellent service. If this oil has a proper degree of viscosity, it will spread a continuous film on the point or face of the cutting tool, reducing friction and preventing abnormal heating and wear. The oil should flow freely through the pump and supply tubes. It is not necessary to employ the higher-priced mineral oils, screw-cutting oils or mixed lard oils for this class of work. This grade of oil is also suited to many operations on the lathe, miller, keyseater, etc., where an oil lubricant of comparatively light body is indicated. It not only keeps the tools cool, but wears well on the usual classes of work performed on the latter type of machines.

For steel sheet punching and for some classes of drawing work where the materials are not too heavy this grade of oil makes a satisfactory lubricant. It will be found, in competition with water lubricants, on steel sheet to show a lower cost per running hour or per machine. It also keeps the dies in better condition, reducing the amount of grinding. For the heavier work of drawing cups or shells from heavy steel sheets an oil of greater body is necessary. This may be prepared by mixing lard oil and mineral oil in proper proportions.

Detergent Effect of Water Compounds

The advocates of water compounds will dispute the wisdom of employing oil for drawing work, but it is always better to use oil, except on lighter drawing processes, unless a reduced cost per operating hour or a reduction in total consumption cost can be shown to be accomplished by the former. The claims of great savings effected by the water compounds are frequently not borne out in actual practice. They also exert a detergent effect on machine tools in many cases, while oil maintains the dies and presses in good condition. The factor of evaporation in compounds into which water enters largely as an ingredient is also so great as often to render their adoption uneconomical and often prohibitive.

A large number of manufacturers still cling to the practice of using screw-cutting oils or mineralized lard oils on the greater percentage of their work. This practice in many cases is neither warranted nor indicated by the conditions. A very large percentage of the work in most factories, with the exception of tapping and threading operations on steel and copper, can be done with a good quality of mineral oil with far greater economy. This oil can be purchased at prices not exceeding 12 to 15c. per gallon.

Some manufacturers prefer a mixture of lard oil and fuel oil or of lard oil and kerosene in various proportions for cutting lubricants. These mixtures are used in bolt-threading and nut-tapping machines and also in automatic and hand screw machines. While the initial cost per gallon is below that of lard oil and mineral oil in equal proportions, fuel oil or kerosene is not recommended because of the low flash point of these oils. It is doubtful, also, if these formulas give the same degree of durability as the equal-part mixture of lard oil and mineral oil.

The subject of cutting lubricants into which water enters largely as a component part of the formula deserves careful consideration. The number of these compounds offered on the market in recent years has greatly increased. The manufacturer is pressed to make a trial of each new brand, with the assurance that it is far superior to anything previously put forth, both in the quality of the mixture itself and in the reduction of consumption cost made possible by its use. The arguments of the salesman are frequently clinched with the statement that the new compound is the result of years of study on the part of some scientist whose discovery the dealer has been fortunate enough to secure and is now ready to sell the manufacturer at prices that will revolutionize the expense of tool lubrication.

Confusion in Lubricant Practice

The progressive manufacturer desires to adopt all reasonable measures to keep in the front ranks of those aiming toward efficient management in business, with the result that he tries out many of these so-called new compounds, hoping thereby to save large sums of money, as he has been definitely assured he can do. All this experimenting tends to confusion in the lubricant practice in his shops and may in the end work injury to his machine-tool equipment, unless these tests are confined to a very limited number of machines in one department and are conducted for a long period of time before the use of the material is extended.

A large percentage of the cutting lubricants prepared with water have a detergent effect on metal surfaces, tend to wash the oil from the bearings and slides and to gum the working parts of machine tools. Many dealers claim that their compounds do not have a corrosive effect on metal surfaces and that the soluble oils, of which the better grades of these compounds are composed, lubricate and preserve the bearings and slides of the machines. That the oil portion of these compounds counteracts to a considerable extent the chemical action of the water is conceded.

In general, lubricants having water as a component part are not recommended for automatics, hand screw machines or any class of machines of the turret type where there are numerous working parts—exposed or otherwise—with which it will come in contact. The factor of evaporation is so great in the case of water solutions and the wearing quality or durability of these solutions so much below that of good oils as to render the economy effected a somewhat negligible quantity, when the maintenance of machine-tool equipment in prime condition is considered. And this is a most important item of expense in the large factory, bearing a direct relation to the investment in new tools. It is also true that in many instances carefully conducted tests will indicate the running cost per hour, or for a definite period, of a water compound to be in excess of that of a mixed lard oil, properly proportioned, or of a good grade of mineral oil, while the arguments in favor of the employment of oils on the previously mentioned types of machines are enhanced by the fact that with the use of oils the danger of corrosion is entirely eliminated.

Water compounds may be employed to advantage on certain classes of work and on certain kinds of machine

tools where the working parts are few and the danger from the action of water is reduced to a minimum. On plain horizontal lathes and on lathes of the Gisholt type, machining steel, etc., and on millers and drilling machines operating on both iron and steel the use of these compounds is indicated. They give excellent service, also, on coldsaw work.

In using water compounds on gear-cutting machines special care should be exercised in selecting a mixture that will not in any degree, however slight, gum or clog, as otherwise the index feed may be thrown out of true.

For the lighter machine operations, including plain drilling and milling processes, a simple standard soap compound of good quality may be employed to advantage. For vertical drilling machines of the automatic-feed type these soap compounds are adapted to quite a wide range of work on steel and iron. They are sufficiently viscous to afford a fair amount of lubrication to the point of the tool, and at the same time the tendency to heating is largely overcome by the large percentage of water.

On account of the composition of soap bases and rapid evaporation of water these compounds require more or less frequent addition of water or of the stock solution, in order to maintain a proper degree of specific gravity throughout the run. The initial cost is attractive to the consumer, and this should not exceed from ½ to 1c. per gallon for the solution when prepared ready to load into the machine.

A Good Compound for Many Operations

A good compound for the heavier classes of work, such as milling steel, cutting off steel on coldsaws and turning, boring and facing of steel castings on lathes and boring mills, may be prepared by the manufacturer within his own plant by combining a good-quality soap base with pure lard oil, soda and water in proper proportions. The proportion of lard oil entering into the formula should be graded from 1 to 5 gal. per barrel of solution, according to the class of work to be done. These mixtures will range in cost from 2 to 8c. per gallon.

This formula gives good service on a variety of operations on metals where the employment of a water compound of heavy body is indicated. It forms a strong, viscous solution that flows freely, supplying abundant lubrication to the point of the cutting tool and at the same time reducing the temperature to a minimum. The life or wearing qualities are excellent, due to the percentage of pure lard oil entering into its composition. It will be found to meet the severest conditions under which a water compound may be expected to work to advantage, while the initial cost of the several proportions or degrees of strength of the formula is lower in most instances than the various dilutions of the so-called soluble oils on the market. In general, the weakest form of the solution, costing approximately but 2c. per gallon, will do the work of mixtures costing from 30 to 50 per cent. more.

A good compound for grinding cams and cones and finishing shafts may be made by combining lard oil and mineral oil with a soap base, soda ash and water in proper proportions. The cost of this mixture should not exceed ½c. per gallon ready to load into the machine. Notwithstanding this low initial cost, it proves a most satisfactory lubricant for this class of work. The tendency to hold metal dust in suspension is minimized to a degree that renders it specially adaptable to automatic grinders for various classes of finishing operations. The quality of work obtained is equal to that secured by any of the more costly preparations.

Applying Soluble Lubricants to Tools

It is of the utmost importance in operating machines with soluble cutting lubricants that a strong, full stream of the fluid be supplied to the tool. The success or failure of a lubricant often depends upon this factor as much as on any other. It is sometimes desirable to supply the lubricant to the tool from different angles with more than one feed pipe, in order to flush the cutting point or edge to the fullest degree possible and also to lubricate the work.

The method of application has more to do with results than most overseers or tool operators appreciate. In shops where a number of machine tools are grouped or arranged in series a system of overhead tank and piping, conducting the lubricant to each individual tool of the group, affords an efficient method of lubrication. Sufficient compound to operate all the machines for a given length of time can be prepared and loaded into the supply tank, thus simplifying the labor of handling. By the introduction of proper methods of supplying the lubricant, speeds can often be increased and additional cutting tools employed.

As previously stated, the factor of evaporation in all cutting lubricants containing water is important. As it is necessary to add a small percentage of water daily to the tank, after the machine has been started, a careful inspection should be made at intervals to keep the dilution in proper proportion. Unless this is done, the cost of operating may equal or exceed that of clear oil, and no economy result. Since the degree of evaporation varies according to atmospheric conditions, it is not sufficient to add an equal quantity of water on each succeeding day.

Metal dust and other foreign matter with which compounds come in contact in the pan or tank of the machine also affect the specific gravity to a considerable extent. It is desirable, therefore, to use those compounds in which the tendency to hold metal dust in suspension is modified to as great a degree as possible. Where stock solutions of compounds are prepared and stored for future use, the barrels should be tightly headed to prevent evaporation and the solution drawn off through faucets in preference to opening the barrel.

The number of lubricating oils and cutting compounds required in any plant, however large, is generally comparatively limited, and the more simplified the practice the more economical and satisfactory are the results obtained.

Care and Distribution of Oils and Compounds

All stocks of oils and cutting compounds should be kept in a central storehouse under the supervision of a competent person to whom orders can be sent by the various foremen for such supplies as are needed for their current use. All solutions or compounds should be prepared at the oil house and delivered to the departments on signed orders only. It is not good practice to allow the foreman or boss of a department to make up mixtures according to his own judgment of what may be required for his work. This procedure tends to confusion and

prevents establishing and maintaining a uniform practice throughout the factory on similar processes. There is a common tendency among shop foremen to make up mixtures of their own for special jobs or to use a different oil from their neighbors on similar classes of operations and metals. There is not only no economy effected under this method, but on the contrary there is certain to be conspicuous loss. The manufacturer will be constantly called upon to purchase, either for trial or permanent use, some oil or compound not already in stock, to suit the whim or fancy of the individual overseer or workman.

A printed schedule of practice should be placed in the hands of the section superintendents or head foremen of each department, showing the various kinds of lubricants to be used for all classes of work throughout the factory. The oilhouse keeper should be provided with a record giving the formulas he is to prepare and keep in stock. He should also be provided with schedules showing the kinds of oils or compounds to be used in the several departments, together with the names of foremen eligible to draw these materials. An additional list including the names of foremen eligible to draw pure lard oil should also be in his possession.

STANDARDIZING LUBRICANT PRACTICE

With these data he is enabled carefully to scrutinize all orders received and question the filling of any orders calling for lubricants which the foreman is not scheduled to use. By following this system the manufacturer will find that he is enabled to secure absolute uniformity of practice in his shops, and in addition to this he is enabled to control consumption within the limits of production requirements and prevent undue waste.

A good supply of small cans and spouts should always be kept in stock, so that no leaky cans may remain in the hands of the workmen.

Analyses and tests should be made at intervals on all oils purchased, in order to insure against adulterations and also to keep the standard of quality up to the specification as provided for in the original contract made with the oil refiners or dealers.

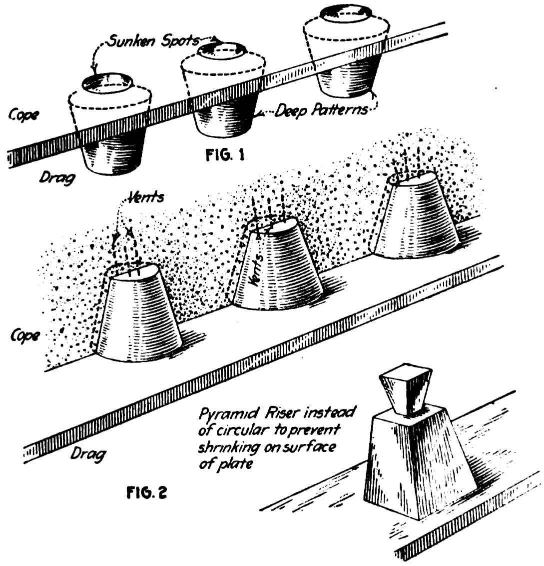
A record should be made of all oils and compounds delivered to the various departments. Regular monthly reports should be issued to the superintendents of sections and also to the head foremen of departments, in order to keep them advised of the rate of consumption and enable them to control the supplies of lubricants used within the portions of the factory under their jurisdiction. These reports are also criticized by the general superintendent or factory economist and the attention of the department heads called to any excess.

Preventing Local Shrinkage in Aluminum Castings

By F. Webster

In making aluminum pattern plates difficulty was experienced from surface cavities opposite each deep part, as shown in Fig. 1. It had been customary to mold these plates with the deep parts in the drag, using a riser over each thick place.

A method of molding them in the cope is now practiced with great satisfaction. The same pattern serves as before, but reversed; and wire vents are made in the sand over each piece. Also, there is used on the plate a riser having a form of a pyramid instead of a cylinder, so as



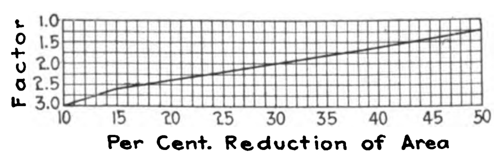
PREVENTING SURFACE SHRINKAGE ON HEAVY PARTS OF ALUMINUM CASTINGS

to prevent a sunken ring around the riser. Fig. 2 shows the arrangement.

[Surface shrinkage on heavy parts is caused by their cooling more slowly than the light parts. It can be cured in many cases by the insertion of metal chills in the mold surfaces of the heavy parts. These equalize the cooling and prevent surface shrinkage.—Editor.]

Power Needed for Wire Drawing

Kenneth B. Lewis, in the *Blast Furnace and Steel Plant* for December, 1915, gives a formula for the horsepower required to draw wire. It is the result of some 60 motor readings made under known conditions and



RELATION OF REDUCTION OF AREA IN PERCENTAGE AND THE FACTOR F

covering a wide range of size and quality of material. The formula is

$$Hp. = T\,(A - a)\,S\,\frac{F}{33{,}000}$$

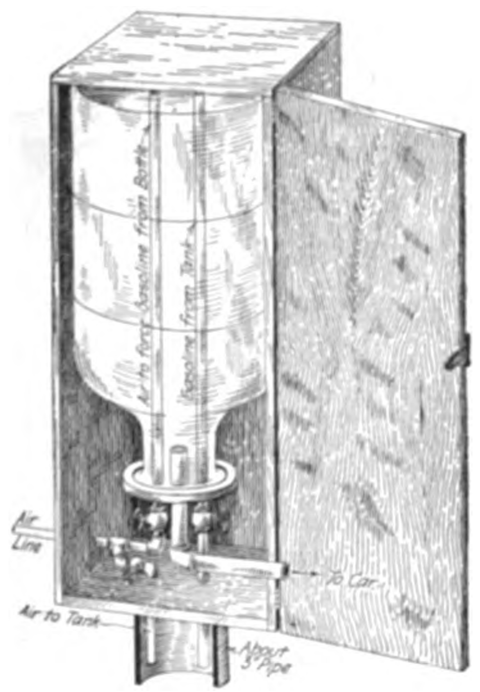
where

T = Tensile strength of stock before the draw, expressed in pounds per square inch;
S = Speed of draw in feet per minute;
A = Area of wire before the draw, in square inches;
a = Area of wire after the draw, in square inches;
F = Factor selected from the accompanying chart.

Letters from Practical Men

Simple Measuring Reservoir for Gasoline

The illustration shows an efficient and inexpensive reservoir for measuring gasoline. It consists of a large glass bottle, bottom up, marked with a couple of bands across the body to denote gallons. The gasoline is forced by air pressure into the bottle from an underground tank.



MEASURING RESERVOIR FOR GASOLINE

When the bottle is quite full, the air is shut off. The gasoline runs by gravity into the tank of the motor car. The customer can see exactly what he is getting, and there is no room for argument about quantity.

Du Bois, Penn. J. M. Ericson.

More Meddling with Weights and Measures

As many readers have learned, there has been introduced in Congress a bill for the abolition of the Fahrenheit thermometer scale. The first section of the bill reads, in part, as follows:

> Be it enacted, etc., that the Centigrade scale of temperature measurement shall be the standard in United States Government publications, the use of the Fahrenheit scale being discontinued, etc.

This bill was introduced by Representative Johnson of Washington and was advocated by him before the House of Representatives in a speech containing all the usual flamboyant gush of a confirmed metricite, a single sentence being sufficient to show its spirit:

> Let us not shift our burden needlessly, sluggishly, cravenly, onto the shoulders of our successors; they will have plenty of burdens of their own. Let us profit by the opportunity to earn high credit for energy and progressive spirit ourselves and to stimulate our successors by our example to earn similar credit in the many lines that will still be open to them.

We are also told that:

> The abolition of the Fahrenheit scale would be welcomed by scientists the world over. The Centigrade scale is used in all countries except in the United States and the British Empire.

The least that may be said of this is that, like most metric statements, it is not true. The thermometer scale of Réaumur is, as is well known, still largely used in Germany, while thermodynamics and steam engineering as studied and practiced in the United States are based exclusively on the Fahrenheit scale; and we suppose that thermodynamics may fairly be called a science.

Dr. Stratton is at least a scientist, and he ought to know that all tables of the properties of saturated and superheated steam and all entropy charts published in the United States are based on the Fahrenheit degree, the pound and the cubic foot, that this bill, which contemplates a change in the unit of temperature, but not in that of weight or volume, involves the use of new steam tables and charts based on the Centigrade scale and the pound and that we have no such tables or charts. It is only recently that satisfactory tables of the properties of superheated steam have been prepared and published at large expense and labor.

Of course, the destruction of these tables is of no importance to the metric mind. Those who have undertaken the infinite labor of this calculation for the public good should, in the opinion of the metric partisans, be glad to see the tables laid on the scrap heap in the interest of the metric hobby.

As in all these cases, the advocates of the measure see nothing in the way but the making of new instruments and the acquiring of new habits of thought, which latter, as usual, they tell us would be acquired "almost instantly and without effort." They see nothing of the confusion due to the break in records. They know nothing of the science of thermodynamics. They care nothing for the wishes of the public. The views of a handful of scientists are paramount.

It is easy to ridicule the Fahrenheit scale; but no one has shown, because no one can show, the slightest advantage in the use of the Centigrade scale. As a matter of fact, for records of the weather the smaller degree of the Fahrenheit scale avoids fractions, and the lower zero point reduces the use of negative temperatures. So far from there being any advantage in raising the zero point, it would increase the use of negative temperatures and the liability of error when calculating average temperatures, as every meteorological observer knows.

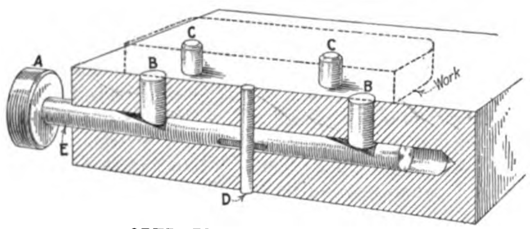
As usual, Dr. Stratton is at the front in this attempt to introduce confusion by upsetting standards of measurement. He is chairman of a committee of the American Association for the Advancement of Science, which has charge of the bill; and he has issued a circular letter from the Bureau of Standards soliciting "expressions of

opinion." Recalling that the Centigrade is the metric scale of temperature, we see again how much faith is to be put in his recent professions that he has little interest in, and is devoting less activity to, the effort to bring about the adoption of the metric system.

New York City. F. A. HALSEY.

Ejector for Jigs and Fixtures

An efficient ejector, shown in the illustration, is of value on jigs and fixtures where the locating is done over two pins. In most cases where an ejector is not provided the operator uses a nail, scratch awl or almost



OPERATION OF THE EJECTOR

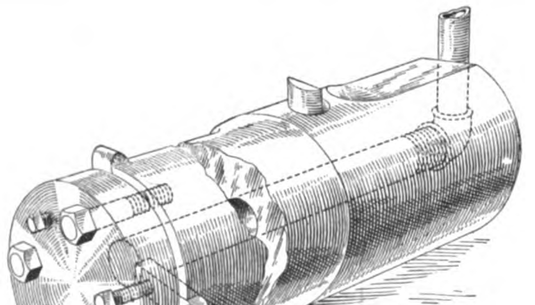
anything to take the work off. This practice not only spoils the tool, but it also loses a lot of time.

All that is necessary to manipulate the ejector here shown is to press against the knob *A*, which causes the pins *B* to push the work off the locating pins *C*. The pin *D* keeps the plunger *E* in place. Any number of ejector pins can be placed on one fixture.

Dayton, Ohio. D. WATSON.

Boring Bar for Shells

The illustration shows a cheap but efficient boring tool for rough-boring the 4.5-in. British high-explosive shell. It is made to fit a hole in the turret and to carry three cutting tools made of ½-in. square high-speed tool steel or stellite. The coolant is piped to the central hole in the bar and squirts out all around the circumference,



BORING BAR FOR SHELLS

directly on the cutting points. The cutters themselves are practically surrounded by the stream of coolant.

The tool was designed after trying out some of the most likely looking adjustable boring tools on the market, but none of them would stand up to the heavy and continuous work of a munitions factory.

Probably the reason why this tool is superior is because it has three cutting points. The absence of small screws and other parts likely to give out is a great advantage where the tools are to be used by operators who are not machinists. JOHN S. WATTS.

New Glasgow, N. S.

Tool Chest for Garages

The illustration shows a tool box used in Waterman Bros. garage, Fresno, Calif. A portable crane hoists the cars up, and the front wheels are placed upon two

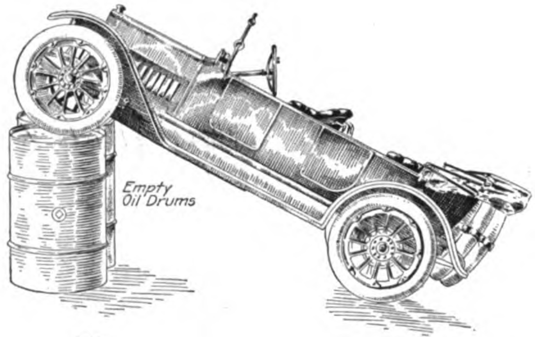


FIG. 1. AUTO ON DRUMS FOR REPAIRS

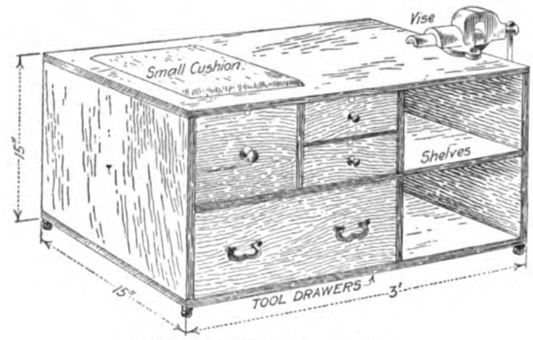

FIG. 2. THE TOOL CHEST

empty oil drums. As no pits are used, this method gives easy access to the bearings and other parts underneath. The car on the drums is shown in Fig. 1.

The tool box, on casters, as in Fig. 2, is pushed under the car. The workman sits on the box to tighten bearings and to fit up new ones. He has all his tools and his vise handy. W. R. SCOTT.

Fresno, Calif.

Drill for Machining Bone

Some green-bone tubes 2 in. long and of $\frac{3}{16}$-in. outside diameter, with walls 0.020 in. thick, were required. The drill illustrated did the work without splitting the bone. A section of bone was first sawed to length, allowing about ⅜ in. for holding in the chuck to finish before cutting off to the required length.

The blank was filed by hand on one end to fit into a $\frac{3}{16}$-in. draw-in collet. By taking very light cuts and feeds the blank was machined its full length to fit the collet, into which it was slipped, leaving about one-half the length exposed. The hole was drilled with an ordinary carbon-steel twist drill.

The drill point, however, was ground, as shown at *A*, by holding it to the corner of the emery wheel as indicated by the dotted curve at *B*, allowing the face of the lip to come flat against the side of the wheel and grinding away each side of the drill center so as to leave it about one-half the original thickness, as shown by the dotted lines *C*. The drill was also ground, one lip slightly longer than the other, which prevented a tendency of the drill to wedge and split the bone. After the hole was drilled to size through the $1\frac{3}{4}$-in. round blank, a round nose tool of self-hardening high-speed steel was used to reduce the outside diameter until the walls were about 0.030 in. thick. Then emery cloth served to bring the diameter to finished size. The tool was ground to shape in the same way as for turning metal but was kept sharp to avoid crowding the thin tube and breaking it.

DRILL FOR MACHINING BONE

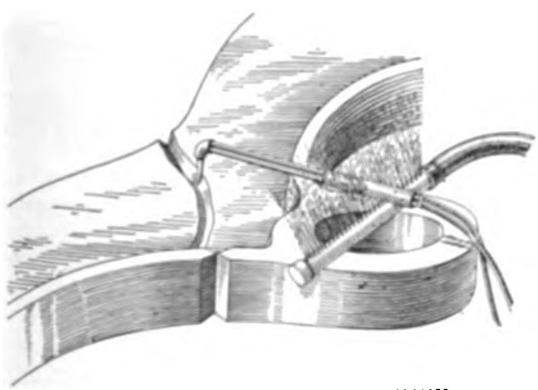
In turning so long a tube of this diameter a short section should be brought to size first, then another short section and so on till the length required is brought to size. Care must be taken not to crowd the drill too fast, and the chips should be removed frequently.

Rochester, Minn. GEORGE G. LITTLE.

Oxyacetylene Welding Kink

The failure of a heavy welding job can often be traced to the discomfort of the operator. To stand up to a large preheated casting is often quite a task.

Where air pressure is available, the device shown in the illustration will be found useful. A row of small



OXYACETYLENE WELDING KINK

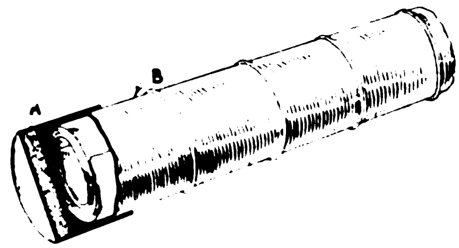
holes is drilled in a pipe of convenient size to attach to the air hose. The other end of the pipe is closed.

This contrivance is placed across under the torch and held by a clamp or a weight in such a position that a curtain of swiftly moving air passes between the hot casting and the operator. The device affords protection from the heat and does not interfere with the manipulation of the torch or obstruct the view of the operator.

Watertown, Mass. H. HOWARD.

Blueprint Tube

The cover of the tube containing the blueprint paper was of the type that pulls off and was not a good fit, thus allowing the paper to spoil. I turned down a felt wheel *A*, about $\frac{3}{4}$ in. thick, to the right size and



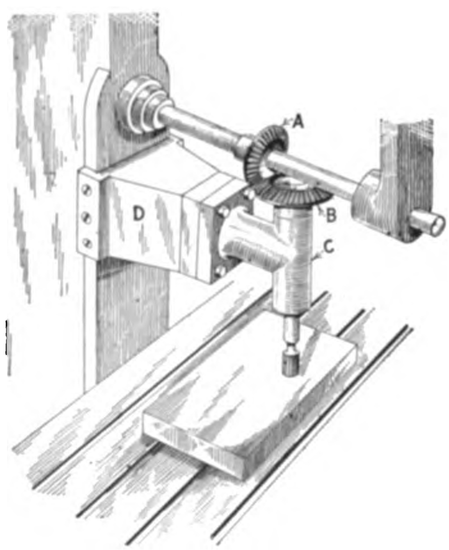
BLUEPRINT TUBE

then shellacked it to the inside of the cover. The tube *B* now hits the felt, making a good joint, and I have no trouble in keeping the paper.

South Sudbury, Mass. HERBERT A. PRATT.

Profiling Attachment for the Horizontal Miller

A simple efficient profiling attachment connected to a plain horizontal miller is shown in the accompanying illustration. Fastened to an arbor of the machine is the bevel gear *A*, which drives the bevel gear *B* and thus transmits the vertical motion. The casting *C* is made



PROFILING ATTACHMENT FOR THE MILLER

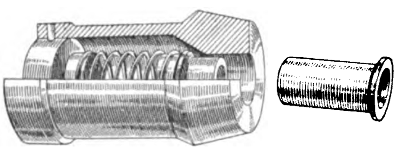
in such a manner as to allow the longest bearing possible for the vertical spindle. It has a bronze bush in which the vertical spindle runs, provision being made for adjustment when wear occurs. The casting *D* is

merely a filler block and should be rugged, to add stability to the attachment generally. This casting is fastened to the ways of the miller by means of gib and screws. J. H. MOORE.

Hamilton, Canada.

Work-Ejecting Collet

The illustration shows a spring collet with a coil spring and plunger fastened in the back end. I use a cupped bumper in the turret head to force the work against the spring plunger when chucking it. By releasing the



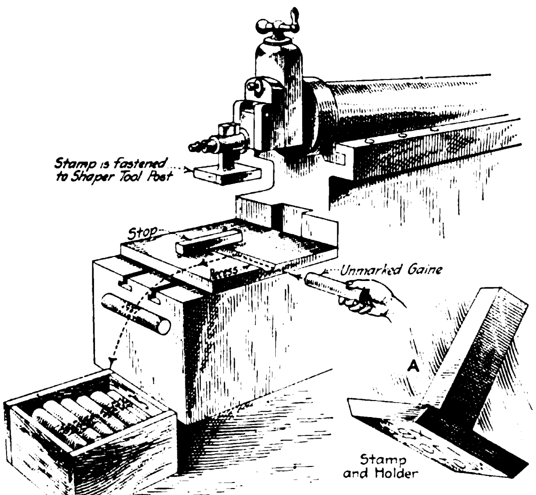
WORK-EJECTING COLLET

collet the spring forces the work out and so prevents the operator from getting his hands caught in the tools while extracting work. I have known this method to increase production 25 to 30 per cent. in some places.

Detroit, Mich. J. E. BRACKETT.

Marking Gaine Bodies in Shaper

The illustration shows a practical and rapid method of marking gaines. A holder *A* is made to fit into the tool post of a shaper. In this holder stamps are inserted, as shown, and the holder fastened into the shaper. A special platen with a stop and a recess, as indicated,



MARKING GAINE BODIES IN A SHAPER

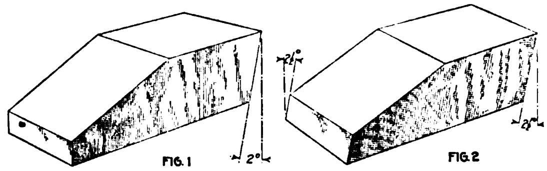
is made to go in the table. The forward stroke of the shaper rolls the markings in nicely, and incidentally no time is lost in withdrawing the gaine.

A steady, heavy shaper should be used to insure satisfaction, as there is considerable upward thrust when the markings are rolled in. The capacity of this machine equals the stroke of the shaper, which should be 1 per second. JAMES DOWNS.

Lynn, Mass.

Design of Holding Jaws

The illustration shows two end views of ordinary "hold-downs." It is contended that the vise jaw in Fig. 1, coming in contact with the angular side of the hold-down, will cause that side to rise, giving to the upper corner of the small side a slight rotary downward



DESIGN OF HOLDING JAWS

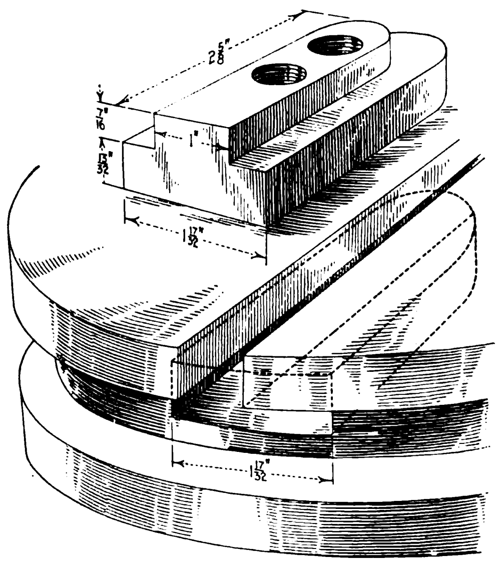
motion on the work that is being held. In Fig. 2 the angle is the same on both sides.

Both sides being parallel, there is a full contact against the work. But it is claimed that this style has not the essential downward action on the work. Which is right? Any information will be appreciated on this subject.

Detroit, Mich. ROBERT J. BEUTER.

Repairing Tool-Holder Slots in a Turret-Lathe Tool Head

The illustration shows how the tool-holder grooves or slots on a 2x24-in. Jones & Lamson turret-lathe head were repaired. The repairs were necessitated by the



REPAIRING TOOL-HOLDER SLOTS

stripping of the threads in the 5/8-in. tapped holes used in clamping the tool holders to the turret table.

The head was milled out with an end mill and T-slot cutter to the dimensions shown. Pieces of cold-rolled steel were then milled to have a driving fit in these slots. FREDERICK W. SNYDER.

Williamson School, Penn.

Discussion of Previous Question

First Wheel Lathe in Brazil

The wheel-turning lathe illustrated on page 596 is of interest, as it shows a simple method of adding electric drive to an old machine tool, but your correspondent is mistaken in thinking that this lathe, installed in 1902, was the first wheel lathe in Brazil.

Wheel-turning lathes were in service in Brazil over 20 years previous to that date, and I understand that the English firm of machine-tool makers, Craven Bros., Ltd., of Manchester and Reddish, which specializes in railway machinery, has been supplying wheel lathes to Brazil since 1878. In 1893 this company shipped direct to the San Paulo Railway Co. a lathe having 6-ft. diameter faceplates for turning locomotive driving wheels up to 5 ft. 3 in. in diameter on tread. With several others, this lathe was altered to electric drive in 1906. Up to quite recent times, interrupted only by their large manufacture of war material, Craven Bros. have been supplying wheel lathes, belt and electric drive, to railway companies in Brazil and Argentina. C. PARSONS.

Alderley Edge, Cheshire, England.

Attitude of Employers Toward Military Training

Percy E. Barbour, on page 867, Vol. 43, and page 33, Vol. 44, brings out a number of good points in connection with military training and desires to interest employers in the matter of arranging for the militia members having leave for local and camp training.

A few particulars of what has been done in this country may be of interest. What in Great Britain are called "Territorial" soldiers are members mostly of units existing until a few years ago as "volunteers." The volunteer movement, which was revived about 1860 from a system in vogue 70 or 80 years earlier, developed into an institution and brought into being corps which in the first instance paid all their own headquarters, provisions, uniforms, and incidental expenses. The government merely provided arms, adjutants and drill instructors from the regular army.

Though enrolled for home defense, legally it was, I believe, somewhat doubtful if they could be forced to serve on mobilization except voluntarily, as the units from the legal point of view were in the nature of private social clubs with members banded together for military instruction. Later, the government allowed a grant of about \$8.50 a year for each efficient volunteer—that is, to everyone who attended, say, 60 drills and a week's camp in two years. This grant assisted in providing uniforms, headquarters, etc.

During the last few years the Territorial army was formed, composed of practically the same volunteer units, but the men were all legally "attested" and bound to mobilize in case of invasion or great national emergency. They also received army pay and maintenance during their yearly fortnight's camp, the government paying all expenses of equipment. A great distinction between the Territorials—colloquially, "terriers"—and the old volunteer is that in the old comparatively haphazard formations one part of the country might have too large a proportion of artillery, another too many cavalry, etc., but in the Territorials the army units are formed of the proper proportion of each branch of miilitary service.

The term Territorial is used because the units are raised in counties or districts from which regular or irregular British regiments take their names. This local connection is real, as local bodies named "Territorial Associations," which include military, municipal, academic and other civilian representatives, administer the government funds and supply headquarters, clothing and equipment, with the exception of arms. The military authorities are responsible for training only. The university, college and senior "public" or "grammar" schools have senior or junior officers' training corps, which have proved useful in providing keen, receptive junior officers. It may be added that a new volunteer movement on the lines of the original one of 1860 has sprung up since the war, composed of men over strictly military age or otherwise unable to serve in the active army. After the usual period of government neglect the volunteer units now are recognized for home-defense purposes, and certain duties compatible with their civilian vocations are allotted them, pay at army rates being granted during their spells of duty.

The Territorial system has proved a great success. Mobilized on the declaration of war, although only attested for home defense, nearly the whole number volunteered for foreign service and after a few months' final training have since served at the various fronts. It has been proved that what many previously considered simply amateur troops are capable of speedy utilization. Probably a matter of 300,000 men mobilized at first, and supplementary units acting as feeders and additions to the first lines will have doubled or trebled the numbers. A great mistake was that thousands of skilled mechanics were allowed to leave the country in the first rush as part of these units, when they would have been of much greater national value as munition workers. However, many men have been brought back, and the mistake will not be repeated. Of course, the enormous amount of ammunition and high-explosive shells needed in present-day warfare has been a revelation to even those who thought themselves really prepared.

The main object of this letter is to confirm Lieutenant Barbour's testimony as to the beneficial effects of such military training on most workmen, especially town dwellers. I can speak both from past personal experience and from that of men working under me who have been induced to join by their comrades.

To begin with, the evening drills take the participants entirely out of the shop atmosphere and give them bodily and mental exercise of an interesting character. Those

who go in for qualifying for noncommissioned-officer rank are compelled to study in order to obtain the proficiency certificates that make them eligible for their rank. Once obtaining them does not guarantee the permanence of the rank; the examination now has to be passed each year. This necessary effort, to my own knowledge, has enabled a number of men to improve their positions both in workshop and civilian life generally. One laborer, for instance, rose to rank as a valued quartermaster sergeant. The greater mental alertness thus encouraged has assisted many men eventually to obtain wage increases of 50 to 75 per cent. Then the fortnight's camp in country, mountain or seaside air, with the regular exercise, plain food and entire change of daily occupation, makes new men of nearly all the members, and the beneficial effect is felt throughout the year.

Many large engineering works have for years had battalions, companies, batteries, etc., specially connected with them, and such units as the Electrical Royal Engineer Volunteers—now Territorials—have been recruited from well-known works, Lord Kelvin being their honorary commandant. The Crewe Railway Works of the London & North-Western Railway Co. used to supply a complete battalion of railway engineers able to cope with any class of field railway work. Both they and the Electrical Royal Engineers furnished volunteer units during the South African War. The Woolwich Arsenal and other armament-producing concerns in other parts of the country have furnished artillery contingents.

Under the circumstances which have arisen the United States will, in my opinion, have only reason for satisfaction if the machine-shop element—all ranks—undergoes some military training on British Territorial lines. Although their services in the first instance might be of greatest value as munition producers, they would then understand and appreciate better the duties of the fighting-line personnel, and after a sufficient reserve of war material had been built up would eventually constitute a valuable reserve for defensive or offensive action.

Manchester, England. JAMES VOSE.

The Buying of Machines--The Production Guarantee

Referring to page 830 under the heading of "The Buying of Machines," I wish to take exception, as a representative of a machine-tool company, to one statement contained in the article, namely: "If he is not willing to guarantee a minimum production after knowing the conditions, we may be justified in looking askance at the machine he builds."

As everyone knows, the conditions in shops vary so greatly in different parts of the country that it is impossible to guarantee production in the shop of the purchaser, owing to the variation in equipment, men, conditions, etc., which are so widely diversified in different sections. For instance, some time ago I installed in one of the largest manufacturing plants a machine for turning certain articles. Previous time on this piece was 6 min. Under a premium system the men were making a slight premium equal to about 5½ min. actual time. Our machine was installed. I set it up, and one of the lathe hands—not a machinist—was put to work on the first run of about 5 hr. duration. The first hour the operator turned 57 pieces, and the final 2 hr. his time averaged 37 sec. for each article. This firm has since installed a number of these machines, and only in rare cases have they equaled this time. I have found in different shops, with the same equipment, which is furnished by the firm that I represent, production differences as great as 100 per cent., owing at times to the condition of the toolroom, whether skilled or unskilled labor is employed, the lighting of the shop, the ability of the executive in charge, the difference in grade of material used, etc.

The machine-tool firm that I represent has made it a practice to give an estimate rather than a guarantee. We feel save in being able to demonstrate to a customer what can be produced in his own shop. It has been the practice among machine-tool builders within the last two years to refuse almost entirely to guarantee production except on special machines—not on standard machine tools. D. R. CLARKSON.

Rochester, N. Y.

"Metricinchia"--A Drawing-Room Disease

A certain disease confined to shop drawings I have taken the liberty of naming "metricinchia." The cause of it is a general mix-up of metric and English measurements on drawings. The reason for English measurements forcing themselves to the front is that the shop in which this disease occurs has generally adopted the metric system. But now and again a case comes up where a Whitworth standard or gas thread has to be used. Then the drawing gets the disease.

I remember being given a drawing for a spindle, a part of which was to be turned ⅞ in. in diameter. This shop would not have the disease on the drawings, so it was sized 22.22 mm. I naturally thought it had to be accurate to $^1/_{100}$ mm. But no, it was not particular! J. H. DAVIS.

Wembley, England.

Wanted--A Lighting Gage

The editorial on page 654 reminds me of the lighting system in a pattern shop where I was employed. A lighting gage would be of little value in this shop, because the room was dark all the time. One large electric lamp furnished light for the pattern makers' benches. This light burned all day. Single lights hung over each machine. Each pattern maker was instructed to turn off the light when he finished using a machine, but the men did not do it.

Here is where the boss got busy. His idea might be a suggestion in shop-lighting economy. The bandsaw and ribsaw lights were operated by means of a spring-released push button located and fastened at the end of each belt shifter. Shifting the belt and starting the saw brought the end of the shifter rod against the push button and thus turned on the light. Reversing the shifter shut off the light.

It is quite possible that similar automatic light-controlling applications will suggest themselves, and in addition to the economy thus effected a higher quality of product results from the enforced use of light when needed.

Kenosha, Wis. J. McCABE.

Editorials

Dr. Stratton's Engine

During the week beginning May 22 there convened in Washington the eleventh annual Conference on Weights and Measures—a body composed of state, municipal and county officials charged with the execution of laws relative to weights and measures. Of it Dr. Stratton is president, and through it more than any other channel, silently and unseen by the public, he is spreading his metric propaganda to the remotest parts of the country.

The proceedings of the session just past show that his preliminary work has been thoroughly done, the body having been converted to the system. Its Metric System Committee brought in a report of the customary kind, extoiling the system to the skies, handing out the regular list of glittering generalities, making the usual charges of ignorance and urging the importance of the adoption of the system. In due course the Committee on Resolutions brought in a corresponding report in the form of resolutions, which were adopted *without a dissenting vote.*

We have in recent editorials pointed out the manner in which, to the facilities of the Bureau of Standards, Dr. Stratton has annexed those of the Government Printing Office and, through the franking privilege, those of the Post Office Department in spreading his metric propaganda. We have now to point out that he has also added the influence of state, municipal and county weights and measures officers directed through an organization of which he is the head and which reaches out from the Bureau of Standards to the Atlantic, the Pacific, the Canadian border and the Gulf. No such engine for the promulgation of the metric system was ever before seen in this or any other country.

These weights and measures officials have to deal with the inspection and regulation of weighing and measuring apparatus and standards used in commerce—that is, in the transfer of ownership of commodities from one party to another with a view, especially, to the detection of false weights and measures. The factory use of weights and measures is beyond their ken and without their knowledge. They know nothing of the meaning of a change in factory units, a shortcoming which, under the circumstances, is not their fault, but their and the country's misfortune. Being under the dominating influence of Dr. Stratton, their attitude is not suprising. We are convinced that an organized effort to educate these officials in the things of which they know nothing is the most pressing need of the hour.

What Is a Gate, and What Is a Sprue?

Surprising as it may seem, there is a friendly controversy in at least one large die-sinking shop in this country as to what part of a set of drop-forging dies is the gate and what is the sprue. Some contend that the small narrow opening, leading from the impression of the die to the larger grooves in the ends of the blocks, where the bar from which the forging is made enters, is the gate and that the enlarged opening which takes the end of the bar of stock is the sprue. Others reverse the meanings of these terms, saying that the smaller opening is the sprue and the larger the gate.

Of course, everyone is benefited if all use the same name for the same thing. While it does not matter whether one part is called a sprue and the other a gate, it is necessary that we should all use the same term for the same thing. In attempting to understand anything of this kind it is always a good plan to hunt for a similar case. Fortunately, one is easily found. The words sprue and gate are well known in founding and were unquestionably used there for many years before drop forging became an art.

Webster's dictionary gives this foundry definition for the word sprue: "The hole through which metal is poured into the gate and thence into the mold." The definition for gate from the same authority is: "A channel or opening through which metal is poured into the mold."

Thus, in founding, the small opening leading outward from the impression in the mold is the gate, and the larger opening beyond the gate is the sprue.

Another way to look at this matter would be to ask what is a gate in our ordinary everyday speech. To every one of us it is a small opening through some inclosing fence or wall. It leads from one large space to another large space. When we seek to apply this meaning of the word gate to the opening in a set of drop-forging dies, we must at once call the small opening leading from the die impression to the larger groove outside the gate and call the larger groove itself the sprue.

Thus both from the parallel use in foundry practice and from our knowledge of the everyday meaning of the word gate it seems wise in drop-forging practice to call the small opening the gate and the larger the sprue.

If there are any readers of the *American Machinist* who differ with this conclusion, they will confer a favor upon everyone by sending in their views.

Prevalence of Resignations

In these days of "war order jobs" not a little disquiet has been caused among employees in the munition sections of the country by the sight of fellow-workmen elevated—sometimes over night—to a supervisory position. Foremanships and superintendencies have been so plentiful that it has become the common practice for men who are dissatisfied to resign calmly enough and obtain coveted advantages in another shop. Their rise is not amid the knocks and bumps of the sidewalk; they go with a rush, as in a high-powered motor car. They do not climb into a desired position, but reach it as in an aeroplane.

There is an old saying to the effect that whatever goes up must come down. Such spectacular advancement

is due to the present delicate, unusual and unstable economic situation. Everyone knows that things cannot continue indefinitely as they now are. When the change comes and things are turned back to normal business conditions, there will be a letting down of many men from positions of foremen and superintendents to the lathe, the bench and the planer. This fact should be clearly foreseen by everyone who is now taking advantage of things as they are.

There is of course no objection to a man's bettering himself—on the other hand, it is his clear duty to do so. But the permanence of that betterment should be carefully studied and provisions made against the day of change, so that when a letting down does come, it will not bring a feeling of unrest.

In the normal order of things few men now in a position of great responsibility have reached that place through an aëroplane ascent. They slowly climbed the slopes and steeps and after mastering each new grade scaled other rocks and overcame other difficulties to reach the next higher elevation. There is really no "royal road" to anything that is good—not even to power. The man who has been carried up a mountain in a motor car is usually very much surprised when he finds himself at the top. On the other hand, there are no surprises to the man who reaches his place of eminence by sturdy climbing. When he has reached the top, it seems natural that he should be there. The preceding difficulties have been overcome, and he is quite as much at home at the top as when he was patiently working his way upward from the bottom.

From a slightly different angle it is altogether wrong to begrudge a man a quick turn of good fortune that puts him above his fellows. It is unwise to covet any position of responsibility unless one is willing to submit to the iron discipline and patient work that seem to be inseparable from all positions of eminence. Too many of us "put aspiration for perspiration, yearning for earning, and longing for labor."

Russian Business and Need of a Commercial Treaty

Exact figures of United States exports to Russia prior to the war are difficult to obtain, because part of our products sent to that great empire was first shipped to Germany. The known exports are $45,000,000 in 1912, and the total was probably at least $80,000,000 yearly for the past few years. All this business should be handled direct, thereby saving the added charges of European middlemen. That these charges are high seems very probable and no doubt did much toward earning for America the reputation of manufacturing only high-priced products.

Another obstacle to our trade with Russia lies in the fact that since the former administration we have not renewed our commercial treaty with that country. It seems to be the general opinion that the victorious European powers will endeavor to obtain great concessions from their allies after the war; and as the *American Machinist* has pointed out before, it is very important that we should have a new commercial treaty signed with Russia at the earliest possible date. The old one was canceled for political effect. This nation has no more right to dictate Russia's internal policies than Japan has to dictate ours. Some of our European competitors seized upon this cancellation of our former treaty to advertise our action all through Russia for the purpose of hurting our trade.

Prior to the war, Germany was Russia's best customer, taking a large proportion of Russia's agricultural exports in return for her own manufactured products. Germany built this trade up from $12,000,000 to $270,000,000 per annum in eight years. It is often the case that warring nations become the best of friends after peace has been declared.

Groups of noncompeting American manufacturers must coöperate and pool their export expenses. They must send a high-class American who speaks Russian to study the market, to educate Russian buyers to American standards (in cases where our standards are more serviceable than those now used) and send home the valuable kind of information that only the highly trained man knows is needed.

The representative will find that Russia's agricultural expansion needs credit for reasons similar to those underlying the development of our Central States 30 years ago, at which time the density of our population and general economic conditions closely resembled the conditions in the Russia of today. We financed the development of our Western States by mortgages. Russia has been financing her development by a system of long credits. Interest rates are high; payment is slow, but sure.

The German demand for accurate credit ratings caused the formation of an agency in Germany that was said to know more about Russian credits than the Russians knew themselves. In every part of Russia, German travelers were found. With characteristic thoroughness they overlooked nothing. We must do likewise! Whenever a complicated machine was sold, the Germans always sent a man to demonstrate it, so that those of our manufacturers who prefer to depend on their catalogs must see that these contain simple, clear instructions for erection and operation. Such catalogs must be printed in Russian, with both American and metric dimensions clearly stated. The Russians have their own system of weights and measures, but it is not necessary to convert the dimensions of our products into those units.

Those American manufacturers who do not wish to send representatives may make arrangements with reliable Russian firms to act for them, furnishing these agents with suitable literature and catalogs printed in Russian or arranging for the printing of such matter in Russia. Catalogs sent out from Germany always gave detailed information showing how to figure the delivered cost at any part of Russia, including the Russian customs dues. As in South America, there are two grades of machinery required—our standard grade and a cheaper but serviceable one for the average buyer.

The laws concerning travelers' movements in Russia are complicated, and a new arrival should take care to ascertain the requirements without delay.

The *Review of Reviews* in advertising its school of character analysis prints this amazing statement: Dr. Blackford has analyzed the characters of 15,000 people. Failures, 0; successes, 15,000. Even the best of us make mistakes, but it begins to look as if there is *one* person on earth today who is infallible.

Shop Equipment News

Automatic Shell-Roughing and Finishing Lathe

Fig. 1 shows a Reed-Prentice 14-in. automatic roughing and finishing lathe for shells, automobile pistons, piston sleeves, plunger and similar work. This lathe is built by the Worthington Pump and Machinery Corporation at the Blake & Knowles Steam Pump Works, East Cambridge, Mass.

The geared head is of the two-speed type. The high speed is through 4-pitch $3\frac{1}{2}$-in. face herringbone gears made in two halves doweled and bolted together; the second speed is through 4-pitch gears having $2\frac{5}{8}$-in. and 3-in. faces. The shaft and spindle are made from a high-carbon steel, running in renewable-type bronze bushings.

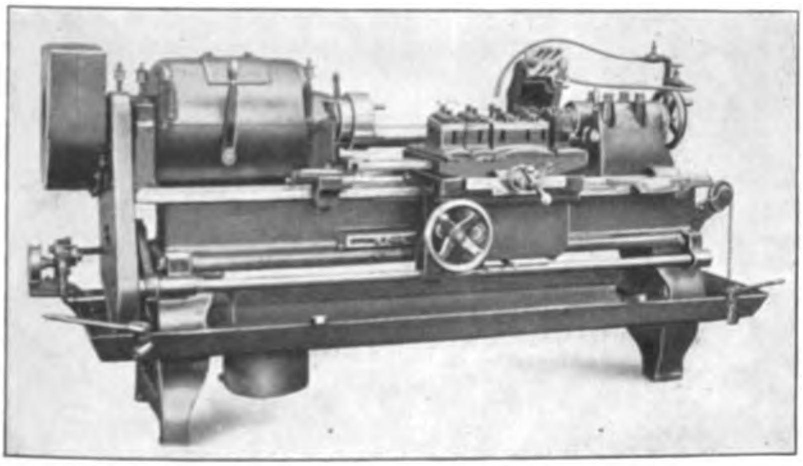


FIG. 1 AUTOMATIC SHELL-FINISHING LATHE
Swing, 14 in.; driving belt, 6 in.; floor space, 11 ft. by 30 in.; weight, 5,500 lb.

The faceplate is equipped with two steel pins for driving the shell, which fits into centers both in the faceplate and the tailstock. The carriage holds three tool posts. One of these carries five tools, which are fed in and out by a cam. The two tool posts, having one tool each for forming the nose, are controlled by a path cam. After the shell has been machined to the required dimensions, the weight shown at the end of the machine draws back the tools and also returns them ready for machining the next shell. A trip arrangement throws the pulley on the crankshaft on the loose pulley. The tool posts are of very rigid design and built to hold the tools without the possibility of chatter. The cam control bar is plainly shown over the ways.

The upper tool post is for facing the butt end of the shell and also for machining the copper-band groove. The desired motion is obtained for these tools by an angular slot in which a roll travels.

Careful attention has been paid to the design of the tail-stock. This is not only exceptionally heavy, but has a somewhat unusual spindle-clamping mechanism. The clamping handle is below the spindle. This leaves the upper surface solid to better resist upward stresses from the cutting tools.

The headstock gears are thoroughly guarded and are provided with a cover that is easily removable for inspection. The gears at the end of the lathe are also well protected, making for increased safety of the operator. The various tools are lubricated by oil, which is forced by a belt-driven pump through the piping shown.

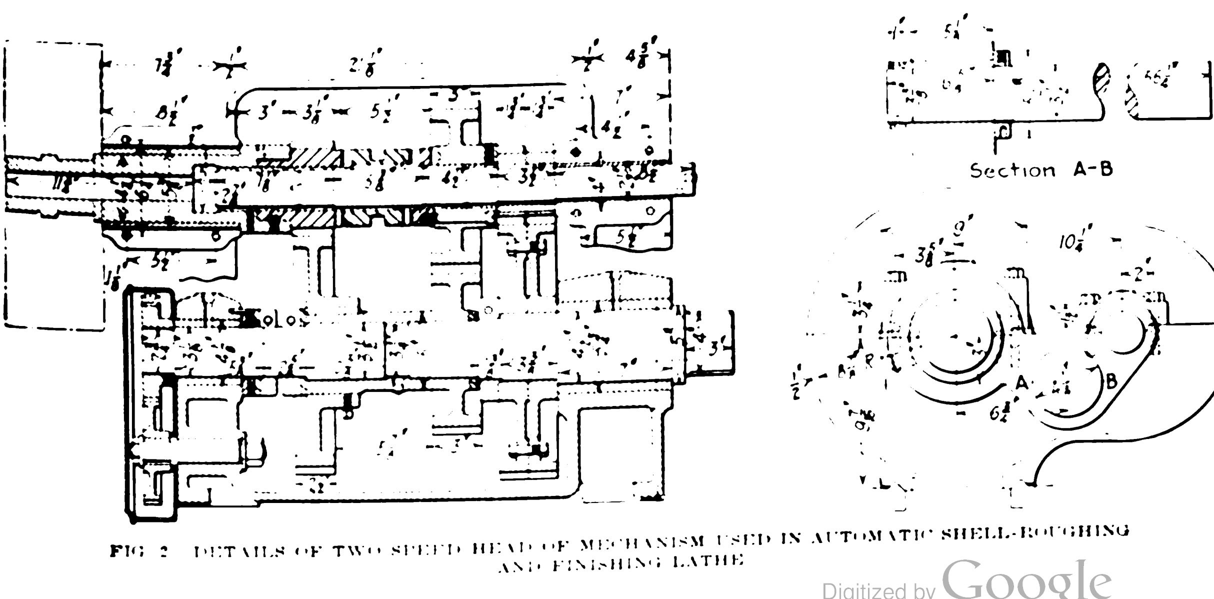

FIG. 2 DETAILS OF TWO-SPEED HEAD OF MECHANISM USED IN AUTOMATIC SHELL-ROUGHING AND FINISHING LATHE

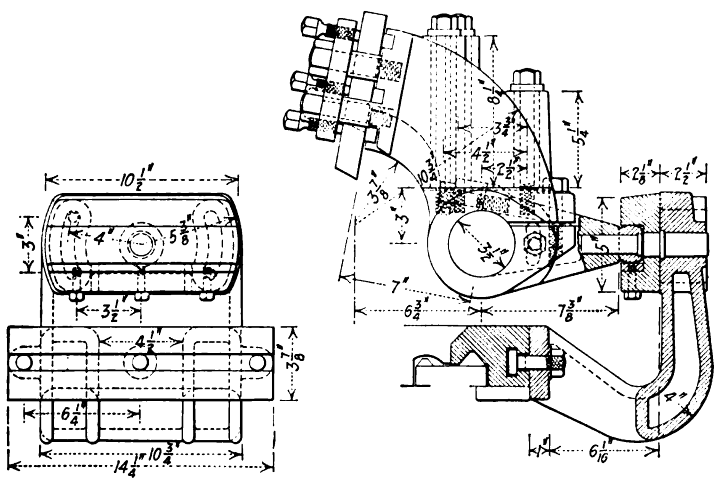

FIG. 3. DETAILS OF BACK ARM ATTACHMENT

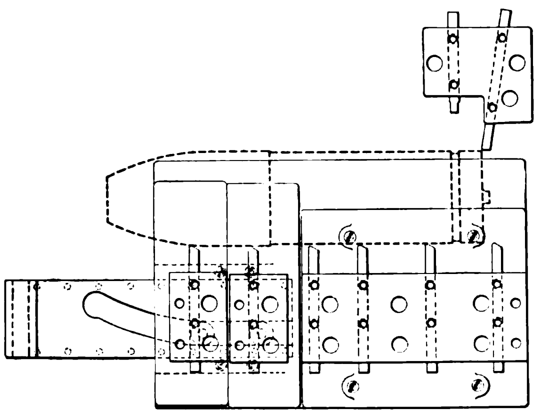

FIG. 4. TOOL LAYOUT FOR TURNING SHELLS

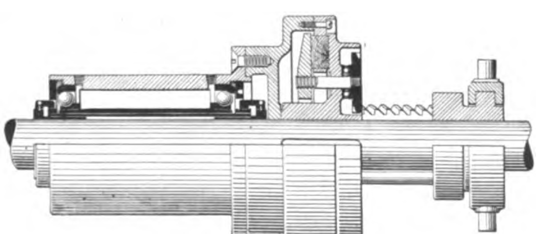
The details of the head construction, carriage and tool layout are shown in Figs. 2, 3 and 4.

This machine, as will be noticed, is of the multiple type, thus reducing the time in machining.

Ball-Bearing Friction Clutch

The friction clutch shown incorporates the standard design perfected by the Hilliard Clutch and Machinery Co., Elmira, N. Y., and described on page 875.

The standard clutch mechanism made by this firm operates satisfactorily up to a rim speed of 5,000 ft. per min., which means that the small-size clutches will operate satisfactorily from 2,000 to 2,500 ft. per min. The great difficulty at such speeds is the lubrication in the clutch sleeve. In the form of clutch shown, this difficulty is overcome through the application of a ball-bearing sleeve, which, as will be observed, provides a large reservoir for the lubricant.



BALL-BEARING SLEEVE FRICTION CLUTCH

It will be noticed that the mechanism for compounding the frictional pressure is of the Hilliard standard rack and gear worm-threaded stud combination. The compounding pressure ranges from 96 to 1 in the small-size clutches up to 168 to 1 in the largest size.

The illustration shows the single-plate type of clutch, in which maple blocks are clamped between the two friction surfaces by means of the rack gear and screw mechanism shown. The ball-bearing sleeve design is clearly indicated.

Special-Purpose and Assembly Arbor Presses

A special feature of the line of arbor presses illustrated is the application of handwheels for exerting the pressure by the use of which there is provided a continuous motion.

The press shown in Fig. 1 is fitted up for molding material which when hot is plastic.

This press is used for forcing a plunger into a mold through the hot material. The mold is then turned upon its side and a second plunger is forced through the hot material. When the material is cool, the mold is placed under projections A and A^1, and one plunger is withdrawn; the mold is then placed upon its end under the points B and B^1, and the second plunger is withdrawn.

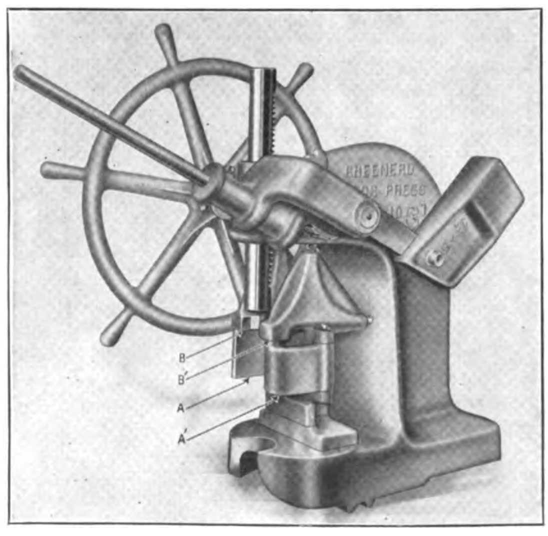


FIG. 1. ARBOR PRESS WITH MOLDING ATTACHMENT

That part of the fixture marked A^1 is swung out of the way when the mold is used lengthwise. The fixture is bolted to the base and held firmly in place by means of

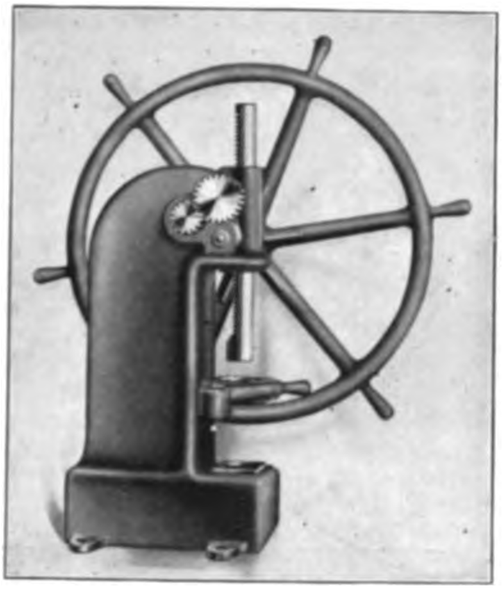

FIG. 2. ASSEMBLING BENCH ARBOR PRESS

four screws tapped into the fixture and screwed out against the press frame.

The 24-in. pilot handwheel is used for withdrawing the plunger. The lever is used for forcing in the plungers. front portion may be swung out on the pivot shown, allowing the work to be placed in position.

The gearing is compounded, two pinions engaging the ram. The wheel may be easily "thrown," so that 2,000 to 3,000 lb. pressure may be exerted on the ram.

The special heavy-base press, Fig. 3, was fitted up for the assembly of parts requiring 600 to 1,000 lb. The guide on the lower part of the rack insures alignment of the parts.

The presses shown are recent additions to the line made by Edwin E. Bartlett, Boston, Mass.

Heavy-Duty Engine Lathe

In the design and construction of the lathe shown the purpose was to provide a machine capable of absorbing the heaviest cuts with high-speed steel cutting tools.

The double-trussed and webbed headstock, with bowl section coming up almost halfway around the cone in front and rear, is designed not only to insure rigidity, by tying together the front- and rear-spindle bearings, but also to safeguard the operator against the revolving pulleys.

The bed is braced internally by crossgirths. At the rear end the bed is cut away to allow the overhang or quick removal of the tailstock or turret. The horizontal and vertical surfaces of the inner side of the front shear are scraped bearings to provide a supplementary bearing for the carriage. The two horizontal bosses cast on the back of the bed are planed to receive taper attachments, radius-arm brackets, and various other lathe attachments.

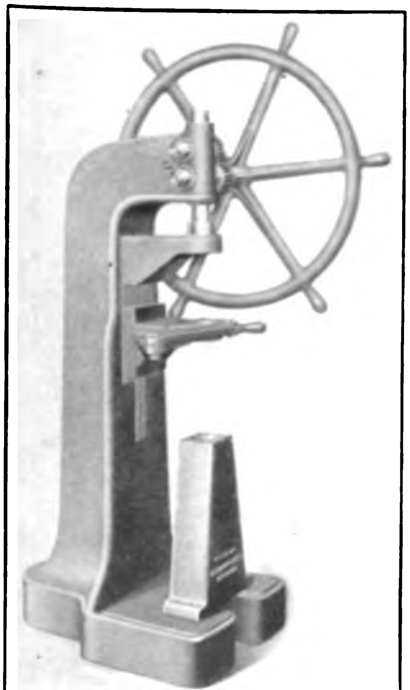

FIG. 3. HEAVY BASE ARBOR PRESS

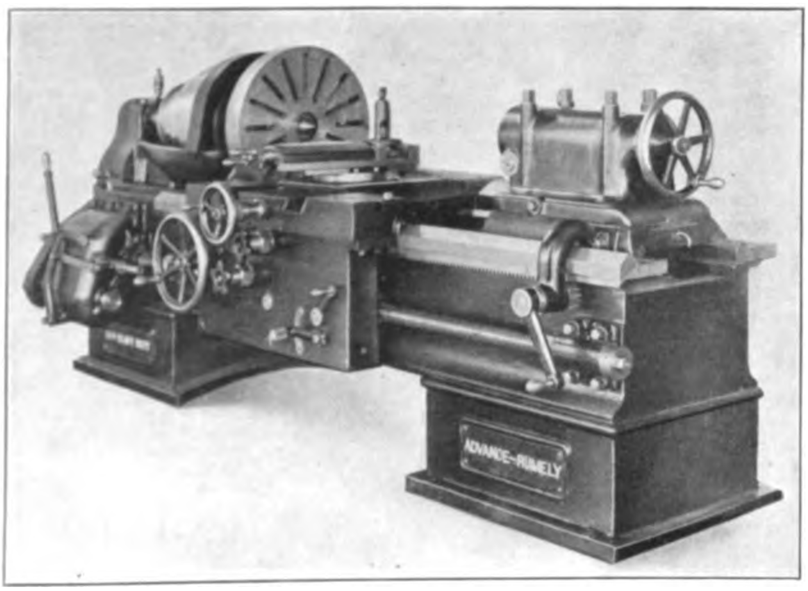


HEAVY-DUTY ENGINE LATHE

Swing over shear, 26 in.; swing over carriage, 17 in.; takes between centers, 10-ft. bed, 6 ft.; hole through spindle, 2 in.; cone-pulley diameters, 20, 16 and 12 in.; back-gear ratio, 10.2 : 1; width of face of cone, 6¼ in.; weight, 10-ft. bed, 10,000 lb.

The press shown in Fig. 2 was originally built for use in assembling. The fixture shown secured to the frame has a hole accurately in line with the ram and the recess in the base. The fixture is divided, the front portion being quickly and securely locked. When unlocked, the

The carriage is 11 in. long on the ways and is provided with T-slots for mounting auxiliary tools, etc. The dovetail on the crossfeed is 12 in. wide on top, and wear is taken up by taper gibs. The carriage takes a right-angled bearing on the inner horizontal and vertical sur-

faces of the bed directly in line with the tool thrust. This supplementary bearing shortens the span of the carriage from the front to the rear V's.

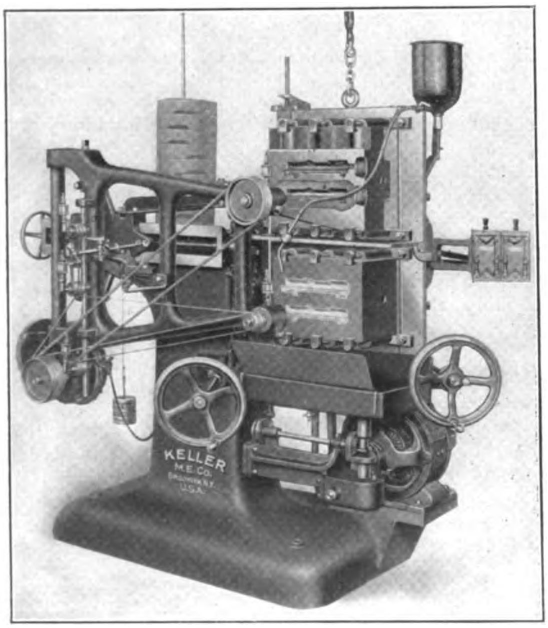
In the apron a back plate that forms a double-walled apron supports the studs front and rear. The apron is tongued and grooved to the carriage in addition to being bolted and pinned. The reverse lever, which shifts the double bevel gear either to right or to left, as the feed is desired, is located in front of the apron. When this bevel gear is engaged, a fixed safety pin prevents the half-nuts from engaging the lead screw.

The quick-change gears are of machine steel, permitting changes while the lathe is under cut. The lead screw passes through the double bevel-gear sleeve and engages it by a key and spline.

The machine is a recently manufactured product of the Advance-Rumely Co., La Porte, Ind., and its sales distribution is in the hands of R. W. Baily, 122 South Michigan Ave., Chicago, Ill.

Automatic Profiling or Die-Sinking Machine

The illustration shows a new size of automatic profiling machine which has been recently produced by the Keller Mechanical Engraving Co., of Brooklyn, N. Y.,



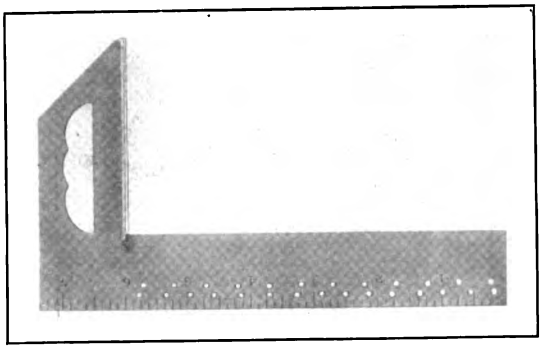
SPECIFICATIONS FOR TYPE E-3 PROFILING MACHINE

Maximum size of pattern, 22x12 in.; maximum size of die block, 22x15x9 in.; feed range, 0.0005 to 0.040; height over all, 6 ft. 6 in.; floor space, 6 ft. 9 in. by 4 ft. 7 in.; weight, including counterweights, 5,000 lb.; drive motor, 1½ hp.; cutter motor, ¾ hp.

and which is known as the Type E-3. The principle of operation of this machine is similar to that of the two smaller sizes, which were described in the *American Machinist* in Vol. 43, p. 653, and in Vol. 32, p. 535, respectively.

Belt-Lace Hole Templet

The templet square shown was designed for correctly spacing holes for belt lacing where the twisted round or wire belt lacing is used in making the joints.



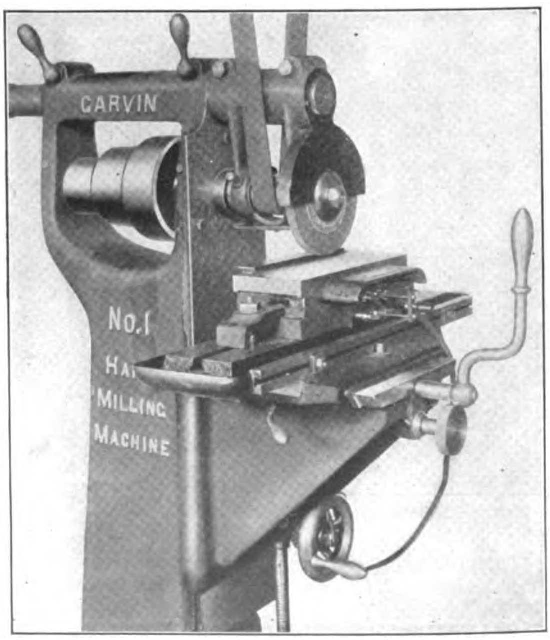
TEMPLET FOR LAYING OUT LACE HOLES

The application is apparent. In addition to its insurance of proper spacing for maximum strength, time is saved. The templet is a recent product of the George W. Southwick Co., Stamford, Conn.

Surface Grinding Attachment for the Miller

In the illustration is shown a compact, rigidly constructed attachment for the miller by the use of which such a machine is readily converted into a surface grinder.

The attachment consists of a double-arm fixture which is clamped rigidly to an overarm. The driving pulley of



SURFACE GRINDING ATTACHMENT FOR MILLER

the attachment is held between two substantial bearings which eliminates the possibility of spring in the grinding-wheel spindle. It will be seen that the attachment incorporates an adequate wheel guard.

This attachment is a recent product of the Presto Machine Works, 119 Lafayette St., New York City.

NEW PUBLICATIONS

STANDARD HANDBOOK FOR ELECTRICAL ENGINEERS—By Frank F. Fowle, editor-in-chief. Fourth edition, 1916 pages, 4x6½ in., illustrated, indexed, flexibly bound. Price, $5. McGraw-Hill Book Co., New York.

The work of preparing this edition was begun early in 1913. It embodies so many changes and so much new matter that it is virtually a new book. The general scheme and features of arrangement which received indorsement in prior editions have been retained. Much of the work of revision has been done by experts selected because of their particular knowledge of the subjects to be discussed. The names of these men appear in connection with the sections for which they are responsible.

As heretofore, this handbook is intended primarily as a reference book of practical information and data for practicing electrical engineers, and as a supplement to textbooks used in engineering schools.

However, there is much matter of value to mechanical engineers and to those who have charge of the installation, operation and maintenance of electrical apparatus in machine shops. One of the new sections, No. 15, "Industrial Motor Applications," must be especially pointed out in this connection. It covers 468 pages and takes up the application of motors to many kinds of machines, with extended references to machine tools and wood-working machinery.

PERSONALS

L. C. Curl, formerly purchasing agent for the Buda Co., Harvey, Ill., is now purchasing agent for the Continental Motor Mfg. Co., Muskegon, Mich.

Henry M. Shaw, formerly Eastern representative of the Gardner Machine Co., Beloit, Wis., has joined the sales organization of the Sherritt & Stoer Company, Philadelphia, Penn.

D. W. Patten, who was associated with the Windsor Machine Co. for several years, has joined the sales force of the New Britain Machine Co. and will look after their interests in the Ohio territory.

Sterling H. Bunnell, for the past nine years connected with the Griscom-Russel Company in sales and engineering capacities, has resigned to become chief engineer of the recently organized American branch of R. Martens & Co.

Lloyd E. Shirley, for a number of years superintendent of the foundry of the C. S. Bell Co., Hillsboro, Ohio, has severed that connection to become associated with the Garland Mfg. Co., Des Plaines, Ill., as vice-president and general manager.

Richard Martens, vice-president and managing director of the shipping and engineering firm of R. Martens & Co., New York City, sailed for Petrograd on May 16, after a six months' stay in the United States during which period Mr. Martens perfected the organization of his American Company.

OBITUARY

Selden G. North, vice-president of the North Bros. Manufacturing Co., Philadelphia, Penn., died at his home in that city on April 24, aged 73 years.

Chester B. Albree, founder and for many years president of the Chester B. Albree Iron Works, Pittsburgh, Penn., died on May 27. Mr. Albree was born in Pittsburgh in 1862. After his start in the mechanical field he became well-known through a number of inventions.

BUSINESS ITEMS

Charles R. Parmele, machine-tool dealer, has moved from 81 Northern Ave. to 50 Church St., New York City.

The Dexter Metal Mfg. Co., Camden, N. J., announce the absorption of the interests, plant and good will of Merritt & Co., steel locker manufacturers.

The Chicago office of James Clark, Jr., Electric Co., Louisville, Ky., has been moved from 201 Machinery Hall Building to its new store and office at 31 North Jefferson St. Oscar P. Wodack, manager.

The Quigley Furnace Specialties Co., with headquarters at 26 Cortlandt St., New York City, has been incorporated and organized to specialize in fuel and furnace engineering. M. S. Quigley, so long connected with this class of work, is president of the new organization.

TRADE CATALOGS

Shaft Making Machinery. Medart Patent Pulley Co., St. Louis, Mo. 32 pp., 6x9 in.

Texaco Crater Compound. The Texas Co., 17 Battery Place, New York. Pp. 32, 6x9 in.

Besly Grinders. Charles H. Besly & Co., 118-20 N. Clinton St., Chicago, Ill. 54 pp., 7x9 in. This catalog gives complete specifications, dimensions and weights for all Besly disk grinders and accessories regularly manufactured.

One Century in Business. Peter A. Frasse & Co., Inc., 417-421 Canal St., New York. 6x9 in. This is an Anniversary Booklet commemorating the one hundred years the company has been in business. It contains very fine pictures of the founder and also of the past and present officers and an illustration of the new electric steel works in Hartford.

FORTHCOMING MEETINGS

Society of Automobile Engineers. Midsummer cruise, steamship "Noronic," Detroit, Mich., June 12-16. Coker F. Clarkson, secretary, 29 West 39th St., New York City.

Master Car Builders' Association. Annual meeting, June 14-17, Atlantic City, N. J. Joseph W. Taylor, secretary, Karpen Building, Chicago, Ill.

American Railway Master Mechanics' Association. Annual meeting, June 17-21, Atlantic City, N. J. Joseph W. Taylor, secretary, Karpen Building, Chicago, Ill.

American Society for Testing Materials. Annual meeting June 27 to July 1, 1916, Hotel Traymore, Atlantic City, N. J. Edgar Marburg, secretary, University of Pennsylvania, Philadelphia, Penn.

American Foundrymen's Association and American Institute of Metals. Annual meeting, September 11-16, Cleveland, Ohio. A. O. Backert, secretary, American Foundrymen's Association, Cleveland, Ohio.

American Society of Mechanical Engineers. Monthly meeting first Tuesday. Calvin W. Rice, secretary, 29 West Thirty-ninth St., New York City.

Boston Branch National Metal Trades Association. Monthly meeting on first Wednesday of each month, Young's Hotel. W. W. Poole, secretary, 40 Central St., Boston, Mass.

Providence Association of Mechanical Engineers. Monthly meeting fourth Wednesday each month. J. A. Brooks, secretary, Brown University, Providence, R. I.

New England Foundrymen's Association. Regular meeting second Wednesday of each month, Exchange Club, Boston, Mass. Fred F. Stockwell, 205 Broadway, Cambridgeport, Mass.

Engineers' Society of Western Pennsylvania. Monthly meeting third Tuesday, section meeting, first Tuesday. Elmer K. Hiles, secretary, Oliver Building, Pittsburgh, Penn.

Rochester Society of Technical Draftsmen. Monthly meeting, last Thursday. O. L. Angevine, Jr., secretary, 857 Genesee St., Rochester, N. Y.

Superintendents' and Foremen's Club of Cleveland. Monthly meeting third Saturday. Philip Frankel, secretary, 310 New England Building, Cleveland, Ohio.

Western Society of Engineers, Chicago, Ill. Regular meeting first Wednesday evening of each month, excepting July and August. J. H. Warder, secretary, 1735 Monadnock Block, Chicago, Ill.

Philadelphia Foundrymen's Association. Meetings first Wednesday of each month. Manufacturers' Club, Philadelphia, Penn. Howard Evans, secretary, Pier 45 North, Philadelphia, Penn.

Technical League of America. Regular meeting second Friday of each month. Oscar S. Teale, secretary, 35 Broadway, New York, N. Y.

FOR SHORT DELIVERY

Lathes For Boring Heavy Shells

36-inch Heavy Lathe with boring tailstock

All Steel Gears

Lathes are equipped throughout with steel gears and are driven by 20-hp. motors. Rear end of spindle is provided with a special thrust bearing of heavy construction to take the end thrust due to boring large holes.

Boring Tailstock

The boring ram is forged steel 6 inches square, and has a very long bearing in the tailstock. The ram feed is driven from the feed shaft, at the rear of the bed, through worm and worm wheel, giving a smooth motion for boring. By means of two levers four feeds can be obtained without changing any gears. These levers are attached to the tailstock and hence are always in a convenient position.

Supports for Work and Boring Ram

A steadyrest is provided to support the shell or other work. There is also furnished a special rest to support the end of the boring ram. This rest moves along the bed with the ram as it feeds.

Specifications, Delivery, Prices, etc., Promptly furnished on Request.

"When interested in a particular line of equipment, I want the best information I can get; and upon the theory that the man who makes the machine knows more about it than anybody else, I apply to him."

Here is a striking reversal of the old order of things of the days of not so long ago, when the spirit of the commercial world was summed up in the injunction to "let the buyer beware."

"Let the buyer beware" implied distinctly that if the buyer did not beware he would, very likely, be neatly "trimmed."

In short, the business men of this "caveat emptor" period had as their sole object the selling of their merchandise. It mattered not how they sold—whether by hook or crook — but *sell* they must.

And now comes our American Machinist reader with a clean right-about-face. When he wants the best information, he goes to the seller.

"Let the buyer beware," was the order of things in the commercial world but a few short years ago. The reverse is fast becoming the order of today. For the seller is the man who must largely supply the facts upon which the buyer has to base his judgment.

And advertising has played no small part in the establishment of this new confidence.

There has been a change in public opinion on the attitude and general responsibility of the maker and seller of equipment.

There has also been a change in the attitude and general responsibility of the maker and seller, himself. This is the prime cause for the change in public opinion.

Note that the metamorphosis of the I'll-get-the-best-of-you-if-I-can seller into the responsible informant with his unexcelled specialized knowledge, is coincident with the development of modern advertising.

Modern advertising, in fact, is both an expression of and one of the causes behind, the responsible character of the present-day maker and seller of equipment and supplies which makes him the man to whom to turn when you want the best information on his particular specialty.

It is the expression of it because no maker and seller of equipment can successfully advertise in a field like the machine industry, without that responsibility and character.

It is a cause for the reason that when a man stands out and begins to tell what he has, he shortly discovers his weak spots and shortcomings — and then at once mends his fences.

There is nothing that makes a man toe the scratch so sharply as to know that somebody is watching him.

The New Technology

EDITORIAL CORRESPONDENCE

SYNOPSIS—The Massachusetts Institute of Technology celebrates its Golden Jubilee this week. Very fittingly this is also the occasion of the dedication of its magnificent new buildings, where the Institute and Harvard University will hereafter coöperate in the education of engineers. This article gives a general description of the grounds and buildings and of the ceremonies accompanying their occupation.

It is quite unlikely that there is devoted to educational purposes any other group of buildings that combine greater advantages of situation and construction than are found in the new grounds and buildings of the Massachusetts Institute of Technology. In the midst of Greater Boston at an imposing place on the Charles River Esplanade the Institute has secured the land and has erected the structure shown on the following page. Incidentally it is of interest to mention that the design, engineering and construction of these buildings have been in the hands of Technology graduates. The method of planning for the new buildings followed an unusual course. Customarily when one wishes to construct a building the architect is called in and all matters are put into his control. Here the beginning was at the other end, and plans already fairly well outlined were put into the architect's hands to be developed in final detail.

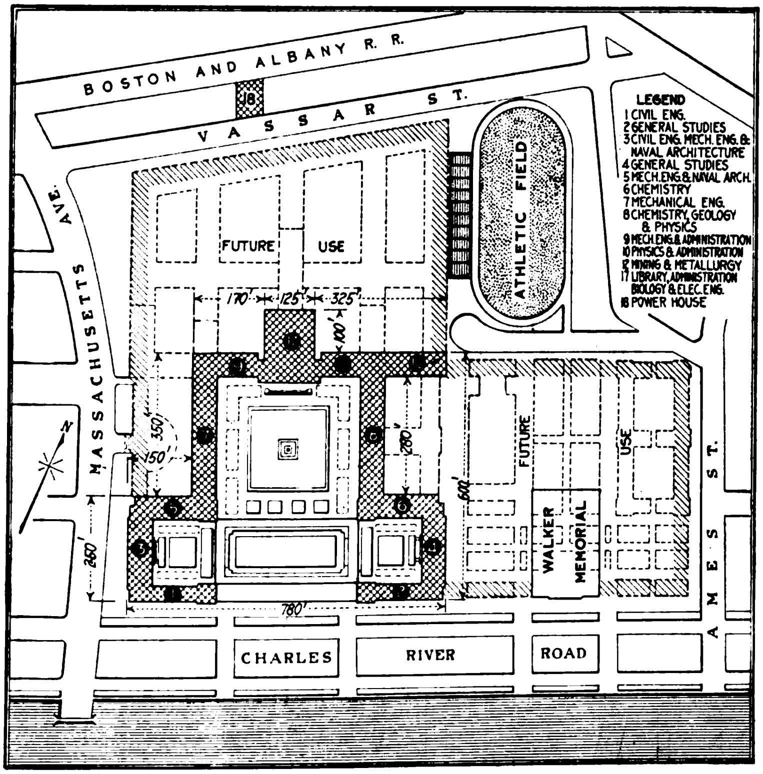

FIG. 1. PLAN OF THE NEW MASSACHUSETTS INSTITUTE OF TECHNOLOGY

When the plot in Cambridge was purchased, President MacLaurin sent first to the heads of all the departments of Technology, asking each one to make plans for his department as if there were no other department in the Institute. The same procedure was requested of the Walker Memorial and Athletic Council, so that well-developed outlines were furnished by men who were themselves experts in planning, being the heads of civil and other engineering departments. When the ideas of these principal men were developed to a degree, Dr. McLaurin called them together; then followed a coördination of the different plannings. The result is now manifest in substantial form, and the Massachusetts Institute of Technology is to move into a new home that from subfoundation to roof is especially suitable for the purpose for which it is intended.

One of the items that was not overlooked was the question of distance to travel. This has impressed itself upon the minds of the students of the present Institute, where, with the several buildings on different streets and quite widely separated, the five-minute interval between lectures proves to be scant time in which to get from one detached laboratory to an equally detached drafting room. The consideration of allied courses was therefore made by the registrar, and those courses which were likely to be taken by the same student in his standard work, or the most popular of the options, were placed in departments close together. In a group of buildings of which the axis is nearly one-half a mile in length, the importance of this arrangement will be appreciated. The educational portion of the new Technology buildings may be described as a connected group of buildings three and four stories in height, attached to, and on each side of, the library. The library is the hub and predominating feature of the construction, and its great dome looks down on the court from a height of nearly 200 ft. This central court, which is open to the river front, expands when near the Esplanade into two large minor courts. These and other courts interior to the buildings insure the necessary lighting of the rooms. These courts are flanked by the department buildings, and the latter are linked together so as to afford circulation under one roof throughout all portions of the structure. It will be unnecessary for the student to be out of doors in passing from one exercise to another, and he may thus avoid the necessity of a raincoat or an overcoat. The buildings receive light from both sides, and all of the drafting rooms are on the top floor, where there are skylights hidden by the parapets.

The fundamental principle of interior construction comprises a system of bays of uniform size, which may be compared to the sectional bookcase in the home library. The floors are hung on the walls entirely free of the partitions. Rooms can be made in any multiple of the unit by merely removing partitions; and since these do not support floors, the desired changes will be easy and inexpensive. Each department may thus have its rooms suited to its future needs instead of modifying its future needs to suit the limitations of its rooms.

In addition to providing for this expansion of room space the plans also permit growth of the various building sections or wings. There is a chance of enlarging the departments in future buildings, and the present constructions afford the opportunity of erecting extensions or wings so that any department may expand into a building suited to its needs. These will be added usually either in one or two directions, but with some departments three directions are possible.

This planning is the result of careful consideration of the needs of the Institute by the various technical men at the head of the departments, in consultation with the architect. Unknown as they are today, the common needs of any department can be met without disarranging any of the other established departments. This provision for the future will assure to the departments about twice as much space as they receive now, when Technology has taken possession.

The great court embraced by the wings opens upon the Charles River Esplanade, the boulevard established by the Metropolitan Park Commission. The frontage of the Technology lot is 1,500 ft. along this, while the length along Massachusetts Ave. is nearly the same. Half of the property is to be devoted to the educational purposes, and the other half will be for social facilities, which the Institute has heretofore lacked. It is the intention to develop the Walker Memorial, an undergraduate club house, gymnasium, commons, a dormitory system and other student features.

The view from the river shows strikingly the splendid proportions of the whole group. It is not possible to get the proper depth of the court from the illustration, but it must be remembered that the central dome of the library is about 600 ft. back from the Esplanade.

Educators from all parts of the world will come to Boston this week for the dedicatory exercises of the new buildings and the celebration of the fiftieth anniversary of the establishment of the Institute.

An interesting spectacular feature of the exercises is the water festival of Monday, held in the Charles River Basin. The Institute will demonstrate to the citizens of Boston the adaptability of that body of water to aquatic sports. In addition to the masque and pageant held in the Court of Honor of the new buildings a spectacle of interest is the formal transfer of the archives of the Institute from the old buildings to the new site. A procession of the corporation and faculty of the Institute will assemble at the Rogers Building and proceed to the basin. Here, after the fashion established long ago in the City of Venice, the officials of Technology will make their first formal entry into Cambridge over the waters of the basin in a Boston-built barge.

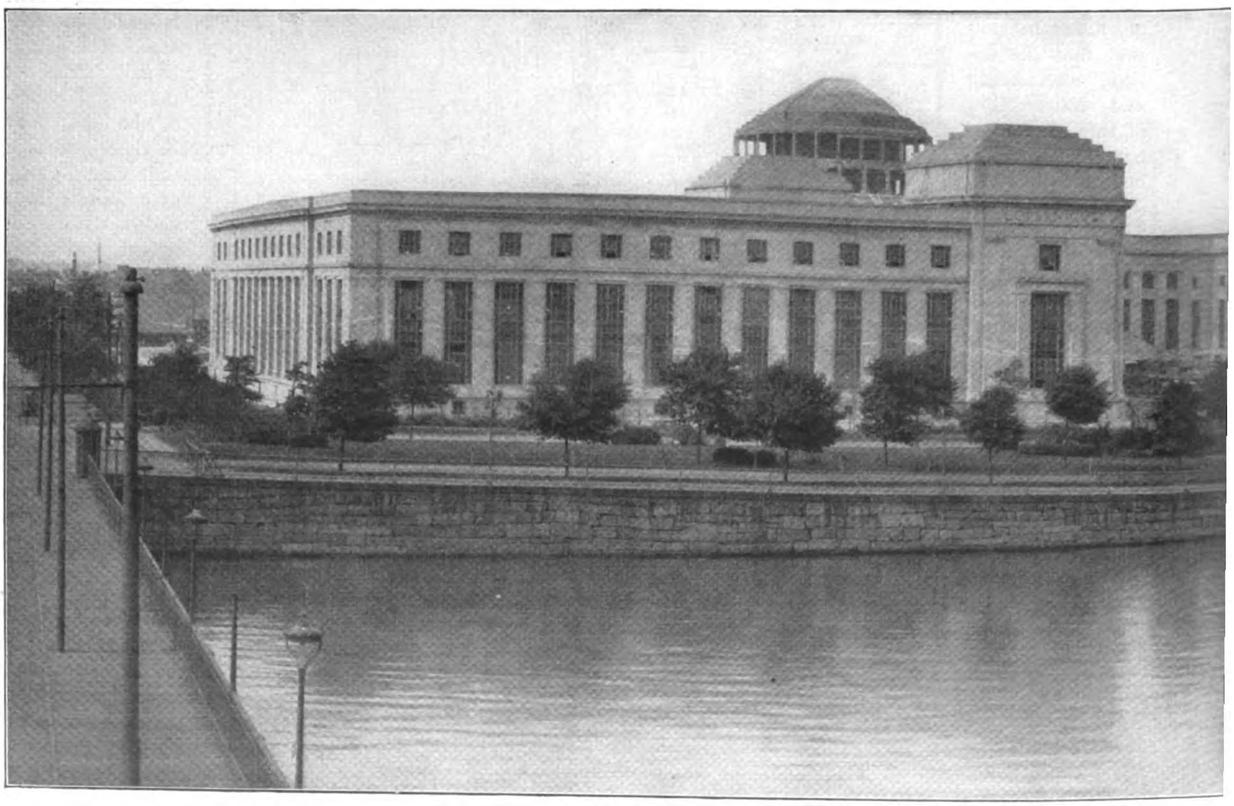

FIG. 2. THE NEW BUILDINGS OF THE MASSACHUSETTS

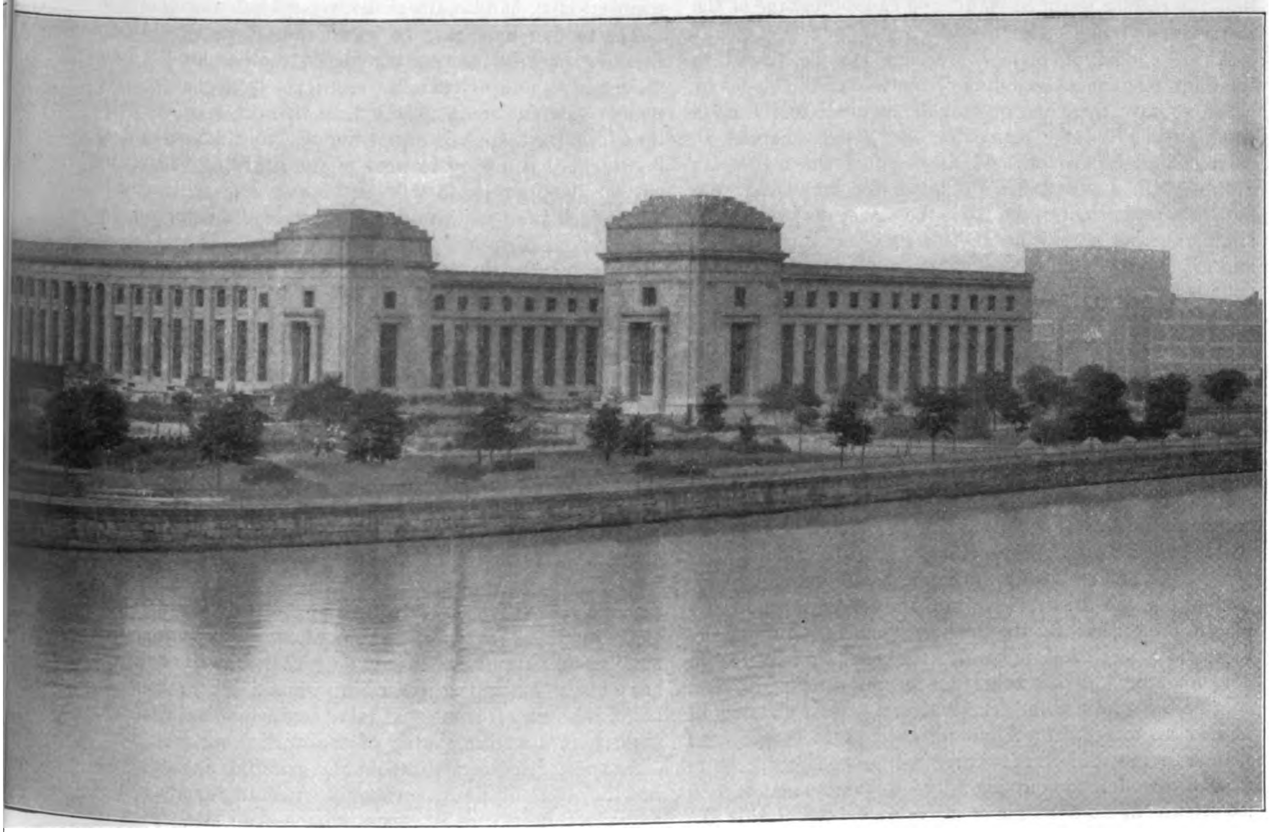
This vessel is something new in American naval architecture. The after-deck rises in tiers following the pattern of the ancient vessels, making an elevated quarter-deck for the highest officials. The rail is broken in places to form entrances to the vessel, and at these points are exquisite decorations. The hold above the lower deck is provided with openings through which the oarsmen propel the vessel on its way. Fifty Technology students have competed with their fellows for the honor of rowing this unique barge.

Boston has wonderful opportunities in the Charles River Basin for the pleasure of its people, but these have thus far been practically neglected. This week, two torpedo boats and a submarine will be in the basin, and a race in pulling crews in boats from the warships stationed in Boston will furnish excitement. The Technology class crews are to have a race, and races of single shells and war canoes will round out the exposition of speed coming from the application of muscle.

Following the exposition of muscle and what is sometimes called the "ash breeze," come examples of speed from the wind, as shown in races of yachts and sailing canoes. Yet another step forward, and speed from power—mechanical power—is to be shown by fast motor boats in action, not only by what we usually understand by "motor boats," but sea-sleds as well and a patrol squadron of five submarine chasers.

Overhead, aëroplanes will perform various evolutions, and a most unusual and interesting demonstration of a man-carrying kite will be made by Samuel F. Perkins, a Technology graduate, who has volunteered to show the results of his studies and invention along these lines. The crowning attraction in the alumni proceedings is the pageant and masque. The court of the buildings furnishes a setting such as is seldom found within the limits of a great city. The buildings will be illuminated with the same degree of skill that characterized the lighting of the San Francisco exposition, the electrical engineer who had charge of the latter being in charge of the illumination here. As the flotilla carrying the faculty and honored guests and bearing the archives of the Institute arrives at the embankment, the signal will be given for the beginning of festivities. In the middle of the court is a space fitted with all the devices of a modern stage. Spotlights will illuminate special features, while flood lighting and vertical rays will give rise to interesting color effects.

In this arena there will be delineated step by step man's progress in conquering the forces of nature. The huge circle will be filled with thousands of elements—students and other participants—in chaos and confusion, a magnificent spectacle of uncoördinated jostling forces. It will be a world without rule. Primordial man sees this world and thinks to conquer it. He is represented by a group of the huskiest of Technology students, selected with care because of their physical prowess. Again and again savage man enters the circle and again and again is flung out by the forces that do not know his bidding. Growing more and more intelligent and calling to his aid great principles working with Reason and Will and Skill—symbolical characters that come to his aid—he subdues chaos, and order and civilization are established.



INSTITUTE OF TECHNOLOGY AS SEEN FROM HARVARD BRIDGE

Grinding Reamers for Steel

By J. B. Murphy

The drawing shows a method that we have tried out during the past two years with very good results in grinding machine reamers. All angles given in the drawing are correct; and if reamers are treated as shown and described, a true, glass-smooth hole will result. Either lard oil or cutting compound may be used as a lubricant, or coolant. Some of these angles for machine reamers are a departure from general usage; but the grinding methods given have been very thoroughly tried out and found highly satisfactory.

Reamers as they leave the factory are certainly not always ground in the most satisfactory manner. To meet the high-speed heavy-production requirements of the day, certain qualities are required, as follows:

First, the reamer must be of exactly the correct shape; and by "exactly" I mean as nearly correct in fluting and dimensioning as mechanical skill can accomplish. If the blades are just a little "under" the center, several results will be very likely to occur. This, in effect, would produce a top rake, giving a thinner cutting edge, which would not "hold up" in service.

Again, the edge at the cutting corner *F*, made by the 45-deg. chamfer, will wear away very rapidly, necessitating frequent regrinding and so shortening the life of the reamer. When the corner becomes dull, the reamer will begin to pick up metal and cause a rough hole. Further than this, an undue strain is imposed upon the lands, and they are quickly worn away, spoiling the reamer, unless it is ground down for a smaller size. Besides all this, the reamer is apt to "bite" and cause breakage of the reamer or twisting off of the tang.

A great deal of reamer breakage can be traced to ignorant, or careless, grinding of the face of the blades by hand, to save the time or trouble required to set up a machine to grind the reamer on the 45-deg. chamfer *B*, as it should be ground. If the faces of the blades are ground with a "backward" rake, as for brass, etc., you have a scraping cut right from the start; and the faults from grinding a rake on the blades occur much sooner and in an aggravated degree.

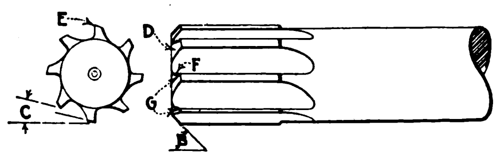
The subject of proportion needs no comment—that is the business of the manufacturer, and here we are to deal with the problem of putting the reamer in the best possible condition for use, to the exclusion of everything else.

Second in consideration, but not in importance, is the cutting edge *E*, which must be well cleared, yet well supported, so that it may produce the greatest possible number of holes before being returned to the toolroom for regrinding. Experience teaches me that this cannot be accomplished by one grinding cut. Two cuts are imperative if the cutting edge is to possess the combined qualities of strength and endurance in the highest degree.

Consider the illustration for a moment. A reamer is placed on centers in the tool grinder and indexed by means of a tooth rest or spring; the machine is set to 45 deg. and, say, $\frac{3}{16}$ in. below the center of the machine spindle for a 5-in. grinding wheel and almost any size of reamer up to $1\frac{3}{8}$ in. A cut is taken at *E*, turning the reamer by hand. This setting will give slightly more than 2 deg. for the cutting edge—an angle that a long experience has taught me to be correct. After this the grinder table is dropped $\frac{1}{4}$ in. farther, making a total for the cutting point of $\frac{7}{16}$ in. below the center of the grinder spindle. A backing-off cut is taken, as at *D*.

The backing-off angle will be approximately 5 deg., or 3 deg. more than the cutting edge. And this angle is also correct if we are to have long service and high production, although some may dispute the efficiency of both angles. A backing-off angle *C*, of 15 deg., like a cutting edge of 5 to 7 deg., is far too great for present working conditions. A 5-deg. angle for the cutting edge gives too sharp an edge to last long, and a backing-off angle of 12 to 15 deg. does not give the cutting edge sufficient support. The backing-off should come to within about $\frac{1}{32}$ in. of the cutting edge as at *G*. For convenience, however, the angles given are variable, to a reasonable extent. All angles may be up to 1 deg. greater than herein given, but never less.

The machine setting suggested will answer for reamers $\frac{3}{4}$ in. to $1\frac{3}{8}$ in. inclusive. For setting other sizes see "American Machinist Grinding Book," Table 33. This table is for milling cutters, but it also forms the best working base from which to calculate the machine settings for reamers. The angles given for the cutting edge of milling cutters form the best backing-off angle for reamers while the cutting edge may be 40 per cent. of this angle. These recommendations consider end-cutting reamers only; hand reamers deserve special consideration.



METHOD OF GRINDING MACHINE REAMERS

The reamer must also be "dead round" on the 45-deg. chamfer, or we will have trouble of another kind. This matter is something that has been grossly neglected. No reamer can cut more nearly true than it is itself. If, therefore, the reamer is hurriedly, or carelessly, ground, it is evident that, owing to wear of the grinding wheel, the cut on the first blade will be heavier and will remove more stock than in grinding the last blade, bringing the reamer "out of round" on the chamfer.

Consequently the outline on the chamfer, or cutting, end resembles an ellipse. A reamer so ground will cut large in direct proportion to the error in roundness. I find that a reamer cutting large for this reason produces a ragged, or scored, hole and that the hole cannot be round. The only remedy is the hand reamer, and even this may not bring the hole true, but merely minimize the evil.

The effect on the reamer is still more serious. The cutting corners of some of the blades are dulled to an excessive degree, causing undue wear on the lands of these blades, not only spoiling the reamer, but also helping along the work of producing ragged, elliptical holes instead of smooth and round ones.

There is one more essential—the sharp corner, as at *F*. It is produced at the junction of the sharpening and backing-off cuts—not the cutting corner, but the one just back of the cutting corner. This should be "broken" by hand, with an oil stone. It takes but a moment and will greatly improve the quality of the work.

I expect disagreement about the grinding angles given, but they have all been thoroughly tried out for upward of two years, operating at very high speed on steel forgings of varying density.

Screw Threads in Small Shops

BY JOHN H. VAN DEVENTER

SYNOPSIS—Every shop has much to do with screw threads, especially in their broadest application as means for holding machine parts together. Many shops lose money through not being "on to the curves" of the simple but sometimes aggravating machine elements. This article deals with various methods of screw cutting applicable to small shops.

When you buy a suit of clothes, you do not give a thought to the unseen thread that holds the pieces of cloth together. But let this unseen thread fail to do its duty in some important seam, and it becomes to you momentarily the most important thing in the world!

There is a close analogy between threads and threads, as applied in the textile and mechanical fields. Both of them hold things together, both have been given the same

FIG. 1. CUTTING ONE SIDE OF THE THREAD SPACE IS BETTER THAN CUTTING BOTH

name; and take either away from its field of application and you put civilization back many centuries.

History does not give us a description of the man who first cut a screw thread, so we are at a loss to know whether this thread was cut to the United States standard, the sharp V-standard, the Whitworth standard, the British Association standard, the French metric standard, the International standard, the Löwenherz standard, the acme standard, the Cadillac standard, the square standard, the Briggs pipe standard, the British pipe standard, the hose standard, the British standard fine screw, the Society of Automobile Engineers standard, the American Society of Mechanical Engineers machine-screw standard, the old standard of machine screws, the gas-fixture standard or the Cycle Engineers standard.

Being a pioneer has its advantages, one of them being that you do not have such a conglomeration of established standards to worry about and choose from. To think of the brain energy that has followed the convolutions of all of these different standard screw threads makes one as dizzy as Mark Twain's "drop of whisky running down a corkscrew." Picture to yourself the numerous conclaves of the wise men of all the nations necessary to establish such an unholy medley of standards, the fuming and fussing and evaporation of brain vapor that were required to invent, establish and sort these 57 varieties! National societies have sat in discussion upon it, universities have deliberated upon it, corporations have investigated it, and in fact, taken all-in-all, this simple mechanical element has had almost as much public discussion as any of the "big" issues of the day.

The regrettable thing about it is that with all this thought, talk and action, while we have standards giving the dimensions, angles and proportions of screw threads, with a few exceptions we have not yet had laid down what is more important for the shopman—the *limits* defining these standards. One of the notable exceptions to this is the A. S. M. E. standard for machine screws, which has been adopted by all tap and die makers.

While there are so many standards to choose from, the small-shop man need not be in a dilemma about which one to take. Outside of repair jobs, which call for special threads, nine-tenths of his work is or should be restricted to the U. S. standard, and the other one-tenth which will call for a finer pitch, should be divided between the A. S. M. E. standard for machine screws for diameters under ½ in. and the S. A. E. standard for the fine-pitch threads between ½ and 1 in. There is no excuse for making special taps in the small shop, and the policy of sticking to these established standards will save money.

Do not attempt to hog repair business by using a special thread standard of your own, for nothing makes the user of a machine more angry than to find that some screw that has been lost or broken is a special one and must be replaced at the factory. You may lose a cent or two of profit by not having the repair order come to *you,* but you are likely to lose the customer's business if you adopt such a small and mean policy. And by all means steer clear of the V-thread. It is not as strong as the U. S. standard and is more easily damaged on account of its sharp edges. When the V-thread and the U. S. standard get together in a shop, trouble begins, especially when one tries to use a V-standard screw in connection with a U. S. standard nut. Nothing but main strength and the compressibility of metal save the day under such circumstances!

Before speaking of the accuracy and errors of screws, it is well to distinguish between the two main purposes for

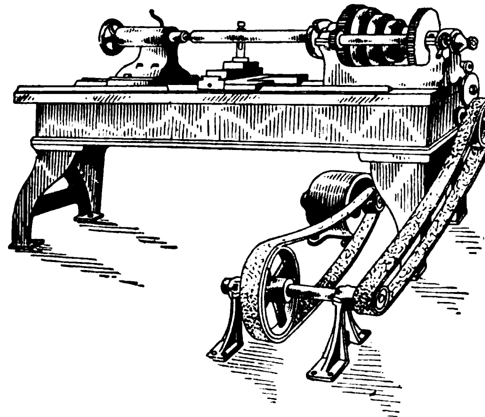


FIG. 2. RIGGING UP TO CUT A "QUICK" LEAD IN THE LATHE

which they are used: One class must be very accurate indeed, this comprising the lead screws, dividing screws and the like, which may be classed as "precision" screws. The broader application as fastenings, comprising bolts, studs, nuts, machine screws and the like, while they do not require the extreme precision of these former screws, must still be held to certain dimensions in order to reduce the shop owner's expense and the shop assembler's profanity, when it comes to putting things together.

In screw fastenings, errors of lead such as are ordinarily found in commercial taps and dies are not important, since the thickness of the tapped piece into which the screw is entered is ordinarily not greater than the diameter of the screw itself. There is small need to worry about slight errors of lead on this class of work, especially if the shop owner gives his taps and dies an accurate inspection after receiving them.

A great deal of tap wear and breakage can be eliminated from both small and large shops by the use of better judgment in the selection of tap-drill sizes. Size for size as compared with other tools the tap does a lot of work. The length of cutting edge in contact with the work in any tap is considerable. It is yanked through metal by main strength or driven through by an unfeeling machine, and in either case the cutting edges suffer accordingly, especially if the tap drill is small. In most places where screw threads are used for fastening pieces together the maximum strength of the thread is not required. It is merely a case of holding one piece of metal to another, and the strain which tends to separate them is not enough to stress the screw to anywhere near its safe limit.

Yet under these conditions you will find no distinction made in the shop as to the size of the tap drill used. In many such cases a drill is selected that is even smaller than the root diameter of the thread, which means that the tap must do the work of a reamer as well as its own. It has been shown that if the threads in a nut are made but 50 per cent. of the full depth of the standard thread, they are as strong as the bolt!

TABLE OF TAP-DRILL SIZES, U.S.S.

(For thread depths equal to 50, 75 and 90 per cent. of full thread)

Diameter	No. of Threads	Tap Drill for 50 per Cent. Depth	Tap Drill for 75 per Cent. Depth	Tap Drill for 90 per Cent. Depth
1/4	20	7/32	13/64	No. 11† (3/16)
5/16	18	J* (17/64)	1/4	D* (1/4)
3/8	16	Q* (21/64)	5/16	N* (19/64)
7/16	14	25/64	23/64	T* (23/64)
1/2	13	29/64	27/64	Z* (13/32)
9/16	12	33/64	31/64	15/32
5/8	11	9/16	17/32	33/64
11/16	11	5/8	19/32	37/64
3/4	10	11/16	41/64	5/8
13/16	10	3/4	23/32	45/64
7/8	9	51/64	49/64	3/4

1	8	59/64	7/8	55/64
1 1/16	8	63/64	15/16	59/64
1 1/8	7	1 1/32	63/64	61/64
1 3/16	7	1 3/32	1 3/64	1 1/64
1 1/4	7	1 5/32	1 7/64	1 5/64
1 5/16	7	1 7/32	1 11/64	1 9/64
1 3/8	6	1 17/64	1 7/32	1 3/16
1 1/2	6	1 25/64	1 11/32	1 5/16
1 5/8	5 1/2	1 1/2	1 7/16	1 13/32
1 3/4	5	1 5/8	1 9/16	1 33/64
1 7/8	5	1 3/4	1 11/16	1 41/64
2	4 1/2	1 55/64	1 25/32	1 47/64

*Letter-size drill; if not available, use size given in parenthesis. †Wire-size drill; if not available, use size given in parenthesis.

The relation between tap-drill size and the elbow grease required to drive a tap is not realized until you have pulled a 2½-in. tap through 3 or 4 in. of steel. I had this experience during the early days of apprenticeship at a Middle Western tool works. The job was given to the newest apprentice, with the idea that while he and the shop helper were pulling their lungs out at opposite ends of a double-end tap wrench he would absorb the first principles of machine-tool building, which in those days was more sweat than science. Fortunately the pipe shop was not far removed, and more fortunately there was plenty of room all around the casting which was to be tapped, so that, before long, science came to the aid with two 14-ft. lengths of 1½-in. pipe that reduced the pull and increased the walk.

But even so it was a slow walk, for the tap had been preceded by a drill that was scarcely larger than the root diameter of the threads and it took close to a day and a half to finish what might have been accomplished in an hour or two at most with equally good results, had the hole been drilled somewhat larger. Nothing on earth could have stripped those threads, I am sure, even had they been half-threads only, for that steel was the toughest material that ever escaped from a steel-foundry scrap heap!

The table of tap-drill sizes given here will enable the small-shop man to use judgment and save his taps. In no case should he use a tap drill smaller than 90 per cent. of the depth of the thread, such as is given in the third column. For machine tapping, a 75 per cent. depth is ample; and in fact if the hole is made smaller, tap breakage will be a considerable item. For ordinary screw fastenings where no great strain or pressure is brought against the parts, 50 per cent. of depth will answer the purpose except in cast iron. The speed of tapping is largely influenced by the selection of the tap-drill size and increases much faster than the percentage of full thread depth decreases.

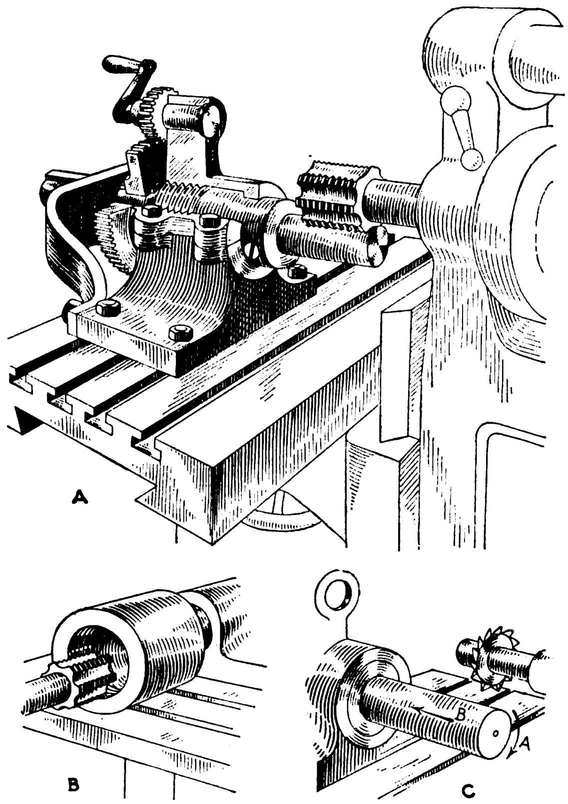

FIG. 3. MILLING THREADS WITH A SINGLE CUTTER AND WITH MULTIPLE CUTTERS

Hand tapping should be looked upon as a very expensive way to do the work; in fact, it should be regarded as similar to the crude method of ratcheting a hole instead of machine drilling it. Even when a close fit is desired, the holes should first be machine tapped with an undersized tap and then retapped to size by hand. Retapping with a sizing tap is the only way in which a large number of tapped holes can be kept to a close standard of size, as has

been discovered by those who have had experience in shell work. This is a natural thing to expect, as the shopman would scarcely think of using any other form tool but a tap for both roughing and finishing cuts, with the expectation of holding size. There is no reason why this cutting tool should be an exception to the rule, and shopmen are rapidly finding that it is not.

The only machine tapper available in small shops is quite likely to be the drilling machine. Even if this is not fitted with reversing gears, a tapping chuck can be obtained that is automatic in its action and that will start to back the tap as soon as the feed lever is raised. These tapping chucks are not only reliable, but are time savers, and no small shop can afford to be without one. When the work runs in large quantities of one or two tap sizes, it is time to consider a tapping machine. Some of these are very simple in construction, and in fact one of the most convenient I ever saw was a home-made affair in which a horizontal spindle was controlled by two friction gears, the tap going into the work when the operator pushed the piece against it and backing out with a fast reverse motion when he started to pull. A contrivance of this kind will tap an almost incredible number of holes without getting stiff in the joints, which is more than can be said for the average vise hand. Probably 90 per cent. of the screws used in the small shops are die cut. Like all female threads, those in dies are infernally hard to measure. The best test of the die is the work that it does; and its offspring being all of the male gender, one can readily measure and inspect them.

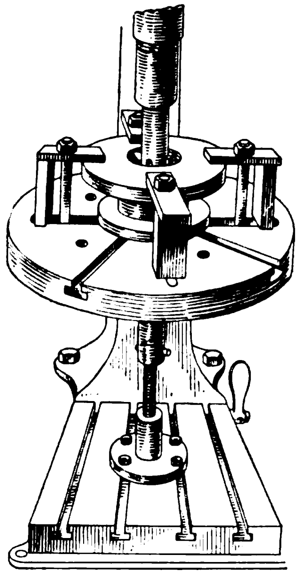

FIG. 4. THREADING WITH A LEADER ON THE DRILLING MACHINE

All threads come originally from the King of Machines, the engine lathe. One of the best kinks in cutting threads on a lathe with a single tool is that attributed to Professor Sweet, in which the compound rest is swiveled 30 deg., so that instead of feeding directly into the work and cutting on both sides of the thread the tool has a one-sided cut, as shown in Fig. 1. This scheme prevents torn threads and is not as widely used as it should be.

Screw Cutting on the Lathe

While the lathe has the ability to develop a thread through its lead screw by means of a single-pointed tool, it is not by any means restricted to such high-grade but expensive kind of work. It will carry either a tap or a die and thus transform itself without protest into a tapping machine or a bolt cutter. And speaking of bolt cutters, some very pretty screw threads are produced on these machines, which are sometimes considered to be crude. Their work is not by any means restricted to threading rough bolts, however, and they can be applied for short feed screws such as are used in blacksmith drills and the like, where the exact lead need not be held to close limits. A bolt cutter will produce just as finely finished threads as a screw machine, for in both cases the quality of the work and the lead depend upon the die, the machine simply being the means of making things go around and important mainly for driving power.

When the small-shop man gets up to leads of $1\frac{1}{2}$ in. or over, he begins to have trouble with the feed works of his lathe. Such leads are not common on screw threads pure and simple, but are not infrequent on its close cousin, the worm, and on some multi-thread screws. In such cases change gears can be saved from breaking and the job may be made easier by rigging up as shown in Fig. 2, on the principle that there is always less strain involved in slowing down than in speeding up.

Accurate Screws on the Thread Miller

Since the advent of the thread miller, the lathe with its single-point tool is not the only machine which can produce accurate screws. A positive lead is used in this milling process, the accuracy of the product, as far as lead is concerned, depending upon the accuracy of the miller lead screw, just as it does on the lead screw in lathe work. The thread miller has another advantage in being a semiautomatic machine and thus slicing off a large portion of the labor required to cut a screw. While a specialized machine of this type is possibly outside the range of most small shops, adaptations of the milling process are not. Some of these are shown in Fig. 3.

At *A* is an attachment rigged up on a plain miller of the knee and column type. The cutter is a plain grooved cutter and has no lead. The length of the cutter is equal to the length of the thread desired on the work, which is held in a fixture having a master screw of the same pitch as the cutter. One rotation of the work mills the entire length of thread and does it in about one-tenth the time that is required by any other method. This is a scheme that has been largely applied to milling internal threads in the base recesses of high-explosive shells where there is not room enough for a tap to clear, the recess at the bottom of the thread being just about equal to the width of one thread. This is shown at *B* in Fig. 3.

Milling Threads with a Single Cutter

It is not necessary to mill threads with a multiple cutter, for they can be handled as shown at *C*, in which a cutter is used having the form of a single tooth space. The work is held and moved as in the previous case. This is the principle employed in thread milling, except that the cutter is moved instead of the work. A more accurate thread can be produced by a single cutter than by a multiple cutter, owing to the changes in form and pitch which the latter undergoes in hardening. Any one of these three schemes may come in handy in a small shop when there is a quantity of work to be done at low cost and yet at a profit.

Even the vertical drilling machine may be made to cut a thread with positive lead and a single-pointed tool if it is rigged up as shown in Fig. 4. There are some jobs too large to be swung on a lathe, which may be handled this way to advantage, although to be sure it is a slow and clumsy way to do the work. Sometimes slow ways are the only ways, however, and this kink should be stored away in the small-shop man's mind for use on an occasion of that kind.

Tools for a Latch Ring

By Robert Mawson

SYNOPSIS—Tools for machining a latch ring for hosiery machines. They employ a large plug in a previously bored hole as locating means.

The firm of Scott & Williams, Inc., Laconia, N. H., manufactures a large variety of hosiery machines. From their practice the various tools used in machining a latch ring have been selected as the subject for this article. The piece itself is illustrated in Fig. 1 on page 1021.

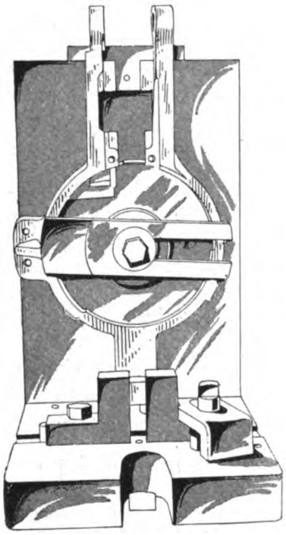

FIG. 2

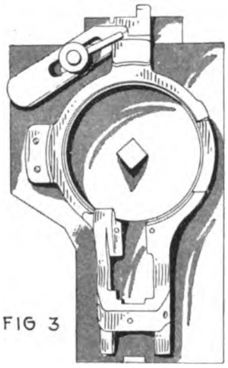

FIG 3

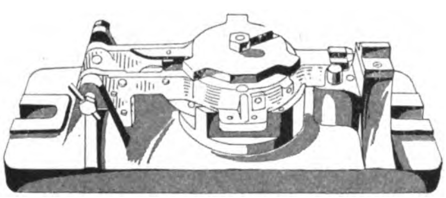

FIG. 4

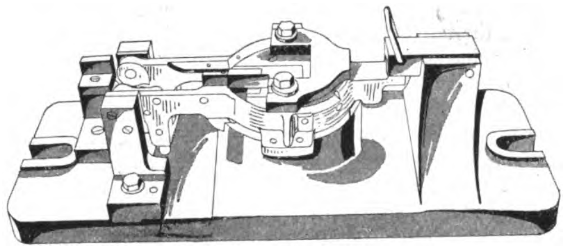

FIG. 5

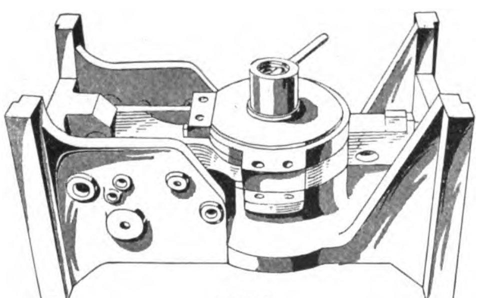

FIG. 6

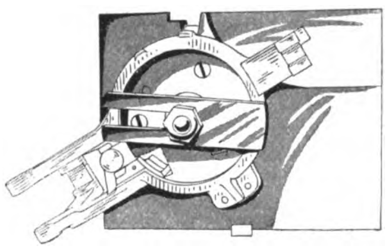

FIG. 7

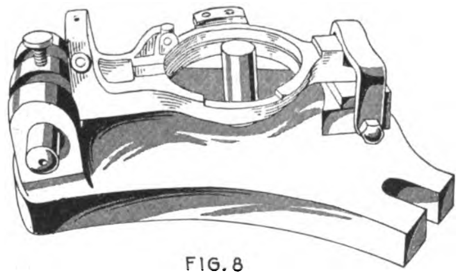

FIG. 8

TOOLS FOR MAKING A LATCH RING WITH WORK SHOWN IN POSITION

FIGS. 2 AND 2-A

Operation—Milling fork end of latch ring, Fig. 1. The casting is located on a $3\frac{31}{32}$-in. plug that fits into the hole bored in a previous operation. An open-end clamp is then tightened down on the casting by a nut.

Surface Machined—Inner surface at fork end, using an 8-in. by $\frac{3}{8}$-in. milling cutter operating at 200 r.p.m.

FIGS. 3 AND 3-A

Operation—Milling pads at back end of latch ring, Fig. 1. The casting, on a $3\frac{31}{32}$-in. plug, is tightened by a nut.

Surface Machined—End of back end, using two $3\frac{1}{2}$-in. by $\frac{1}{2}$-in. milling cutters operating at 200 r.p.m.

FIGS. 4 AND 4-A

Operation—Milling front end of latch ring, Fig. 1. The casting is placed on a $3\frac{31}{32}$-in. plug and located in contact with an adjustable screw. The washer is tightened by a setscrew.

Surface Machined—Tongue at the front end, using two straddle mills 3 in. by $\frac{3}{8}$ in., operating at 140 r.p.m.

FIGS. 5 AND 5-A

Operation—Milling outer surface at back end of latch ring, Fig. 1. The casting is placed on a $3\frac{31}{32}$-in. plug and located by a swing clamp that fits over the milled tongue.

Surface Machined—The fork end of the casting, using a milling cutter 4 in. by $\frac{7}{16}$ in. wide, operating at 140 r.p.m.

FIGS. 6 AND 6-A

Operation—Drilling and reaming latch ring, Fig. 1. The casting is placed on a plug fitting into the large center-bored hole and located by a steel tongue in the machined fork.

Holes Machined—One $\frac{23}{64}$-in. and one No. 5 drilled, one No. 19 and two No. 28 drilled, one $\frac{15}{64}$-in. drilled, two $\frac{1}{4}$-in. spot-drilled and reamed, three No. 33 drilled, four No. 20 drilled, one $\frac{3}{8}$-in. spot-drilled and reamed and one No. 31 drilled.

FIGS. 7 AND 7-A

Operation—Milling surface on latch ring, Fig. 1. The casting is placed on a plug and located by a pin in the milled surface at the fork. It is then held by the open-sided clamp.

Surface Machined—Notch on edge of casting, using a 5-in. diameter by $\frac{31}{32}$-in. wide cutter operating at 160 r.p.m.

FIGS. 8 AND 8-A

Operation—Last milling on latch ring, Fig. 1. The casting is located by a $\frac{3}{8}$-in. pin in the reamed hole at the fork. The tongue is set in a groove and held down with a clamp.

Surface Machined—The pads on the face of the casting, using a 1-in. end mill operating at 200 r.p.m.

THE JIGS AND FIXTURES SHOWN ARE MADE WITH THEIR BASES OF CAST IRON. THE PINS, SCREWS AND STRAPS ARE OF MACHINE STEEL, CARBONIZED AND HARDENED. THE LOCATING SURFACES AND GUIDE BUSHINGS ARE TOOL STEEL, HARDENED AND GROUND. ON THE MILLING FIXTURES TOOL-STEEL SURFACES ARE PROVIDED AND SET BLOCKS TO ASSIST THE OPERATOR IN SETTING THE MILLING CUTTERS. MACHINE-STEEL TONGUES ARE FITTED IN THE BASES OF THE MILLING FIXTURES SO THAT THE TOOLS WILL BE PLACED ON THE TABLE IN THE CORRECT ALIGNMENT. ALL BUSHINGS USED FOR GUIDING TOOLS ARE BLACKENED

DETAILS OF TOOLS USED IN MANUFACTURING A LATCH RING

The Purchasing Agent as a Safety Valve

By H. W. Wolff

The mere fact of being a successful buyer on market values, without a working knowledge of the materials bought, makes a purchasing agent nil in value to any company. If the agent is furnished with a requisition for 5,000 ft. of brass rod and is supposed to buy it at the lowest possible price, he would be an expense to any company at $10 a week. Any intelligent clerk could perform the work.

The real purchasing agent has been referred to as a safety valve. To explain the connection, we will suppose that a requisition for 5,000 ft. of brass rod is turned over to a purchasing agent who is following the safety-valve rule and observe how he handles it.

First, he would want to know how many feet of this size were in stock and how many feet were actually required for orders on hand. If he found that with stock on hand only 3,000 ft. was actually required, he would want a good reason furnished before making the over-investment.

Second, he would want a sample or print of the part for which the rod is ordered. If he found it was, say, ½-in. square stock, that a binding-post screw was being made from it—a square head on a No. 10-32 screw—and that about two-thirds of it was waste, he would want to know why a pressed or brazed head would not answer. Further, he would want to know the previous manufacturing cost or estimated cost, if a new part. This he would check against the purchase of finished screws; and if it was found that purchase was cheaper than manufacture, finished screws would be ordered.

Real Points in Purchasing

It is better to let a machine stand idle and figure 6 per cent. loss on machine investment than delude yourself with the idea of keeping it running or have a mistaken opinion, due to company pride, that your output is better than that of the specialist in screws—or any other article—and lose double or triple your 6 per cent. in higher shop cost.

On a requisition for brass castings the purchasing agent would raise the same question of stock on hand and actual requirements. Many a growing concern has lost its ability to pay dividends through excessive stock investment. The surplus stock of materials too often becomes obsolete before sale and is sacrificed at a "junk" price.

Further, on this casting proposition the agent would want to know why a die casting could not be used, eliminating machine work. If this was not practical, then he would question the use of extruded metal to size, ready for machining, thereby eliminating the work of preparing the castings, etc., as extruded metal can be purchased at approximately the same price as good castings. However, if nothing but a casting was practical, he would investigate the pattern, secure a price on castings from the pattern as it stood, then put the proposition to a foundry to make a price on it mounted, two on a board, or split the pattern on a board for machine molding. This change would double or triple the production and automatically reduce the purchase price.

This method of pattern investigation would be followed on gray iron, malleable and steel castings as well. Foundries have been known to take work at a pound price from the pattern furnished and then make duplicate patterns or equip them for machines at their own expense and make the equivalent of double the price. So with every requisition received, careful analysis would be made.

Like a safety valve requiring careful adjustment, the purchasing agent would adjust himself to the working out of reductions in quantities and changes in methods and designs. If he could not accomplish these results without friction, the ultimate savings would be minimized by antagonism of the different units in the organization.

He could not go or send to the stock or order departments and say, "Reduce your requisition from 5,000 ft. to 3,000 ft.," for immediately they would feel that their work, experience and efforts were being criticized. He could not go or send to the engineering department and make a summary request to change the plans of a screw to show a swaged or brazed head without that department's rightly feeling that its engineering experience was being questioned.

Diplomacy in Changing Requisitions

He could, however, go to the order or stock department and talk stock and values to them. He could point out that the additional 3,000 ft. of brass would cost approximately $500 without the lost interest that would accumulate and that for the ultimate good and success of the company a working capital in cash was as important as a large stock. The money to pay dividends would keep the invested capital interested and ready to supply additional money for growth and expansion. Realizing that the saving of lost interest on excessive stock investments would show a larger percentage of earnings and that their future depended on net earnings more than volume of business or stock, the stock keepers would soon begin to read their requisitions and orders differently. They would not say: "Well, order a gross of files; we'll use them up." Instead, they would figure out that a gross of files meant so many dollars and that a quarter of a gross would stock up for at least three months. They would learn to look at their stock as a bank looks at its deposits and not figure it simply in drills or in gallons of oil.

Possible Nature of the Agent's Suggestions

The purchasing agent could go to the engineering department and ask—not give orders or suggestions—if the use of brazed or forged heads had ever been considered, point out the advantage and cost reduction, show how designs affect the manufacturing cost and that reduction in cost through less expensive designs, equally good as far as service and requirements are concerned, means profit to the company and to the department. It would soon be understood that it was not a question of a little screw costing only 2c., but a question of dollars in purchasing and manufacture, and that the little screw at 2c. reduced to 1c. would mean $100 saving on every $10,000.

If the engineers, as naturally they might do, questioned the screw, die casting or whatever it might be, then the agent would have to take up with the engineers the question of reliable concerns who would recommend and guarantee certain articles as well as agree to furnish them. The engineering department would soon learn to be on its "mettle" and that the best engineering talent in the country was competing with it.

Making Piston Rings With Grinders for the Major Operations

By Ethan Viall

SYNOPSIS—The piston rings here described are made from individual castings and not cut from pot forms, as is commonly done. Except for a metallic gap-guard or saddle, the rings closely resemble the familiar type of concentric ring. A feature of the manufacturing process is that grinders are used for all the major machining operations

In making piston rings from pot castings, flaws, porous spots or widely varying grades of iron frequently develop, causing breakage or dead, unresponsive rings.

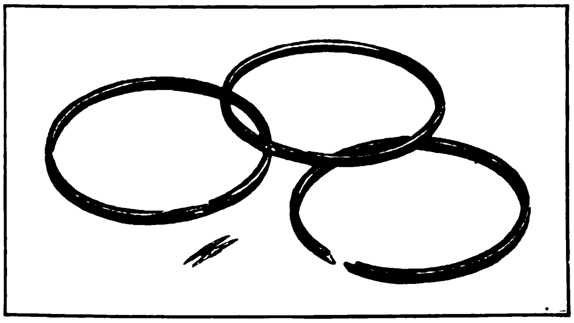

FIG. 1. SAMPLES OF BURD TYPE PISTON RINGS

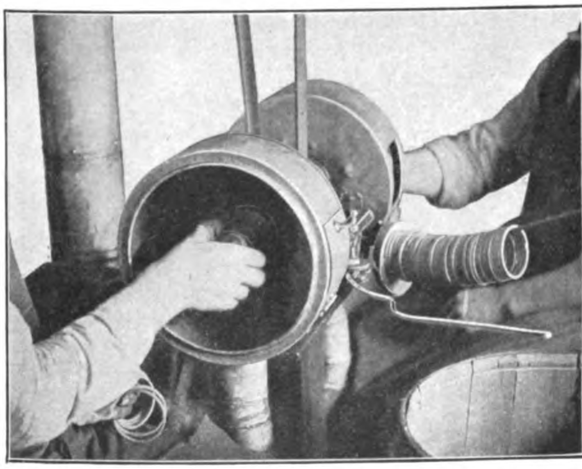

FIG. 3. SNAGGING INSIDE OF RINGS. PRODUCTION: 2,600 PER MAN PER 10-HOUR DAY

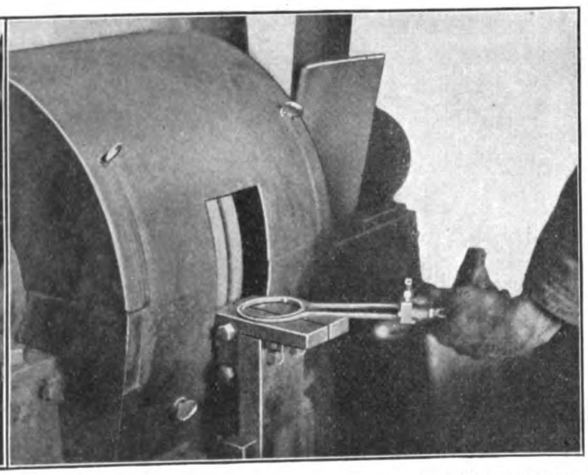

FIG. 4. ROUGHING OFF SIDES OF RINGS. PRODUCTION: 6,000 PER DAY

Individually cast rings, when properly finished, eliminate many of the difficulties encountered in the use of the other type. The Burd High Compression Ring Co., Rockford, Ill., makes all its piston rings from individual castings. These are so handled as to leave the harder skin on the inside of the rings, insuring resiliency and life without the use of objectionable alloys. A special mixture of gray iron finished by grinding on the outside gives a glass-like smoothness when fitted to the walls of the cylinder.

The rings made are of the concentric type, with a pressed-metal gap-guard or saddle that effectually seals the slit, yet allows all the expansion or springiness needed in the ring itself. This will be understood by reference to Fig. 1, where three of the rings are shown; also to Fig. 2, where one is shown in detail. The rings are

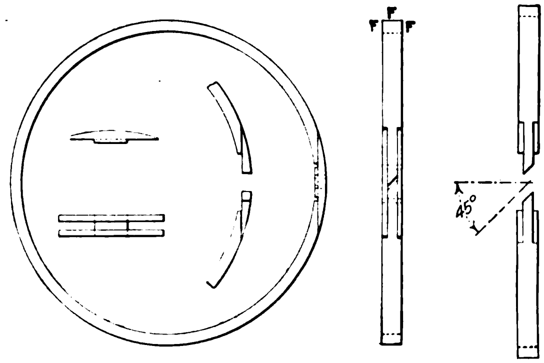

FIG. 2. DETAILS OF A BURD PISTON RING

practically solid, as the objectionable gap is sealed by the saddle. The rings are made in every size called for by the various makers of automobile or other engines. Special testing devices are also used to insure the users' receiving rings of the radial tension which they may specify.

The first operation on an individual ring is to grind the inside, as shown in Fig. 3. This is really a snagging process, and merely removes small lumps or projections and smooths up the inside without removing the skin to any extent. The workman simply holds a ring in his fingers and gives it a rotary motion over the grinding wheel. The wheels are hooded and connected to the exhaust system so as to effectually carry off all dust.

The next operation is the rough-grinding of the sides. The rings are held in a spring holder, as shown in Fig. 4, and then thrust in between the wheels of a Gardner double-disk grinder. This roughs them down to about 0.010 in. of finished size. Outside snagging is the next operation. In this they are held between two flanged holders, as shown in Fig. 5, and revolved against the grinding wheel. This operation, like the inside one, does not cut under the skin of the casting to any extent, but merely removes objectionable lumps. A bunch of the rough rings is shown at the right in Fig. 6, and at the left is a bunch after being ground as just described. It must be understood that while only individual operations are illustrated, numerous machines are employed on each step, both for the same and for different sizes. One of the slitting machines is shown in Fig. 7.

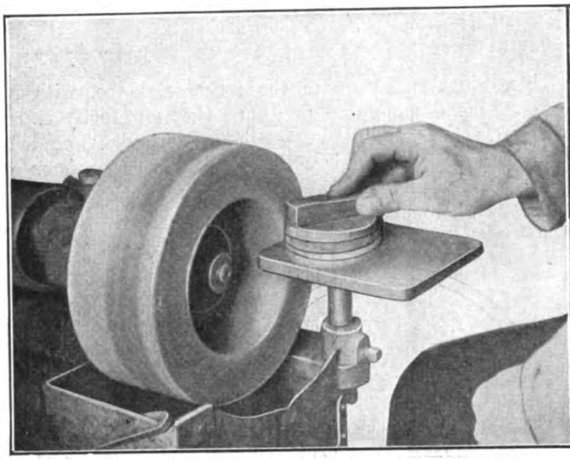

FIG. 5. SNAGGING OUTSIDE. PRODUCTION: 1,700 PER DAY

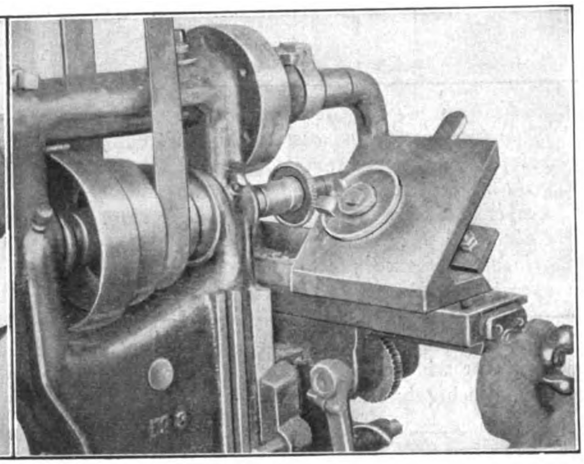

FIG. 7. SLITTING THE RINGS

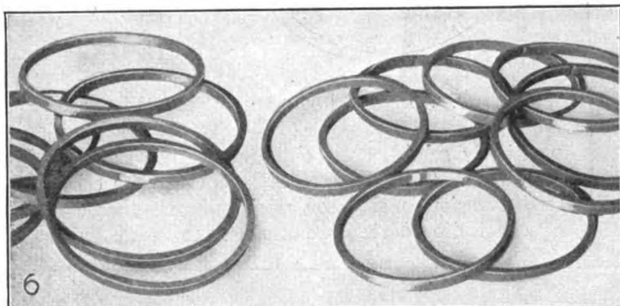

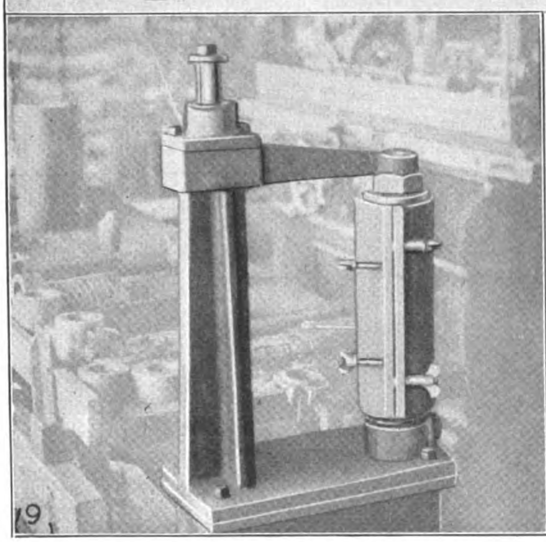

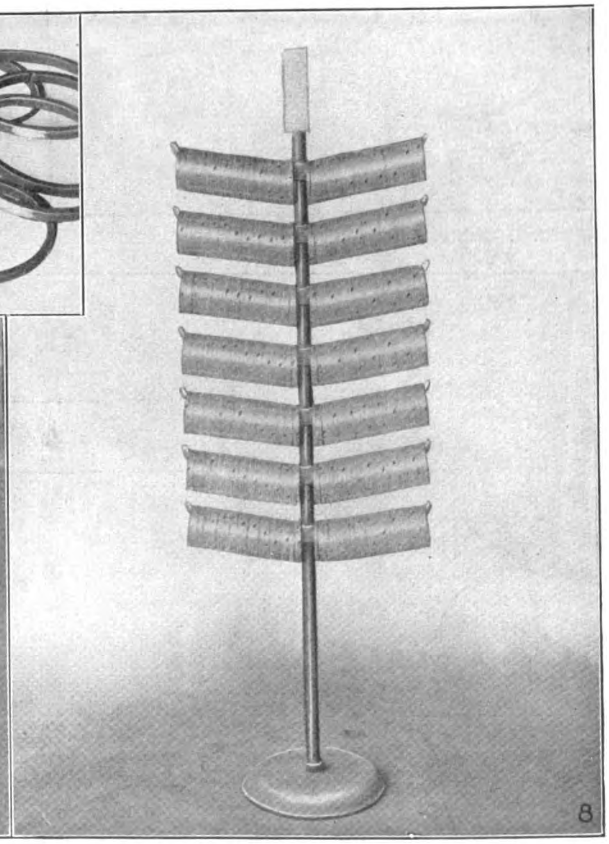

FIG. 6. SAMPLES OF ROUGH AND ROUGH-GROUND RINGS. FIG. 8. TYPE OF WORK RACK USED. FIG. 9. RETAINING SLEEVE AND MANDREL BRACKET

The ring to be slit is held on an angled plate by means of hooked clamps operated by an eccentric lever from underneath. Two milling saws are used on the arbor

After being slit the rings are compressed and placed in retaining sleeves, as shown in Fig. 9. The sleeves full of rings are slipped down over flanged mandrels and

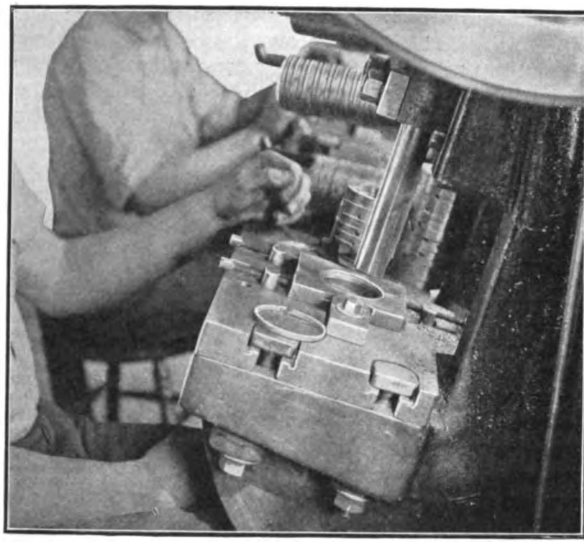

FIG. 10. ROUGH-GRINDING OUTSIDE DIAMETER. PRODUCTION: 3,000 PER DAY

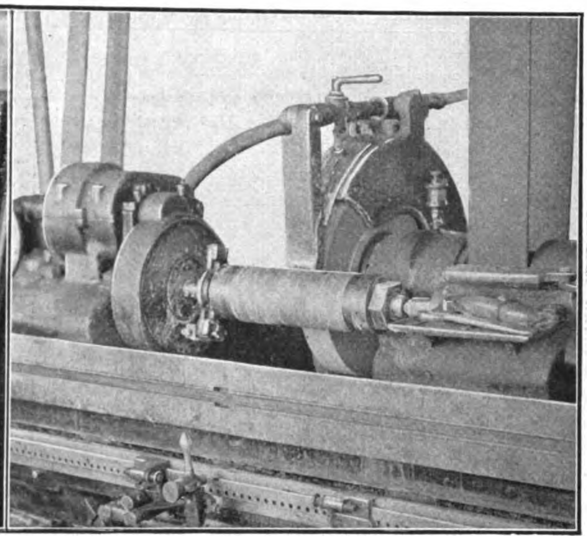

FIG. 11. BROACHING SADDLE SLOT. PRODUCTION: 2,800 PER DAY

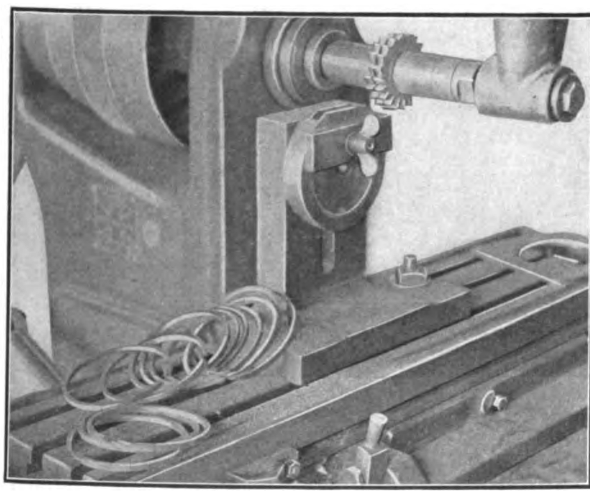

FIG. 12. STRADDLE-MILLING FOR SADDLE. PRODUCTION: ONE OPERATOR, TWO MACHINES, 1,500 PER DAY

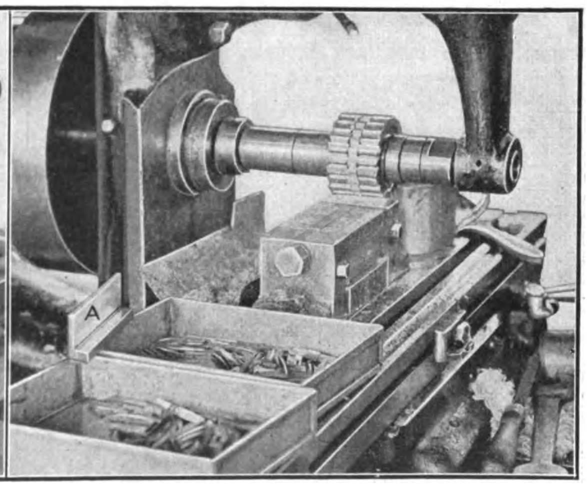

FIG. 14. MILLING BACKS OF SADDLES. PRODUCTION: SIX IN JIG, 1,000 PER DAY

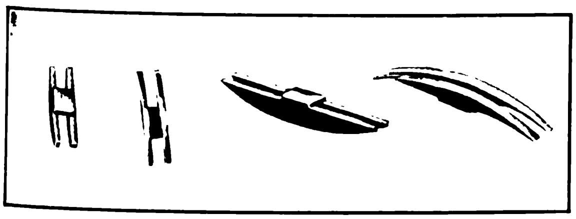

FIG. 13. ROUGH AND MILLED SADDLES

and feeding is done by hand, using the ball crank on the table feed screw. As the rings are slit they are placed on racks like the one shown in Fig. 8. These are used throughout the shop and are very convenient. They may be revolved or rolled from one machine to another with little trouble and no danger of losing their load.

clamped for grinding in the usual way. The mandrel is held in a special fixture while being loaded, and after the sleeve and removable flange with the locking nut have been put in place, the steadyarm is swung over to support the end of the mandrel while the nut is tightened. The arm is then swung out of the way, the sleeve loosened and removed and the loaded mandrel placed in a grinder as shown in Fig. 10. Plenty of water is poured over the work while grinding to prevent warping or distortion.

After being rough circle ground, as just described, the rings go to punch presses, where the slot for the cross-piece of the saddle is broached out. One of the presses is shown in Fig. 11. The ring is compressed so that the two ends are in contact, and then it is placed in the holder shown on the press platen. The broach is

held in the ram of the press and the slot is finished at one stroke.

Next the ends of the ring are straddle-milled for the sides of the saddle. This is done as shown in Fig. 12.

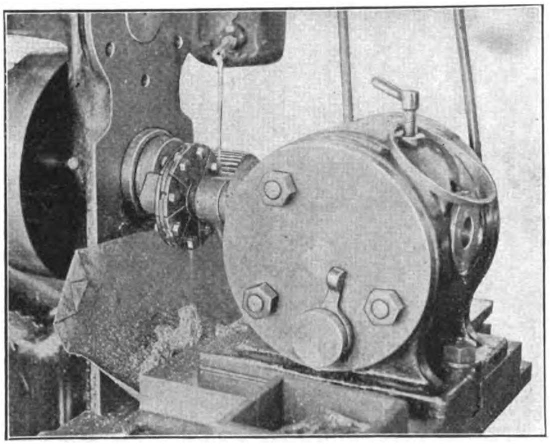

FIG. 15. MILLING RADIUS ON SADDLES. PRODUCTION: 1,500 PER DAY

are first milled as shown by the third one from the left, and then the radius is milled as shown at the extreme right. The milling of the backs is done as shown in Fig. 14. The rough saddles are set into the jig and are located by means of the setting gage A, which is laid over the corner of the jig, and the ends of the saddles butted against it. After being located the clamp bolt is tightened and the gang mill run across.

The radial milling is done as shown in Fig. 15. This is a continuous operation, as the holder revolves all the time. The operator removes the milled saddle as it comes up and clamps in another between the split flanges of the holder.

Numerous burring operations are interspersed at various places between grinding or machining operations. Fig. 16 shows a group of girls busy burring saddles after the milling operations. Fig. 17 shows a boy burring and assembling rings and saddles. Large numbers of both girls and boys are employed for the burring operations at various stages. After the rings have been burred and assembled, they are placed on magnetic chucks and the sides ground to size as shown in Fig. 18. The operators on this operation work in pairs. The first operator grinds one side and passes the ring to the second

FIG. 16. BURRING SADDLES

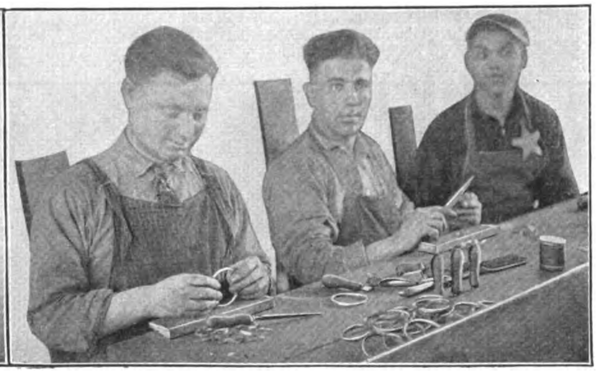

FIG. 17. BURRING AND ASSEMBLING

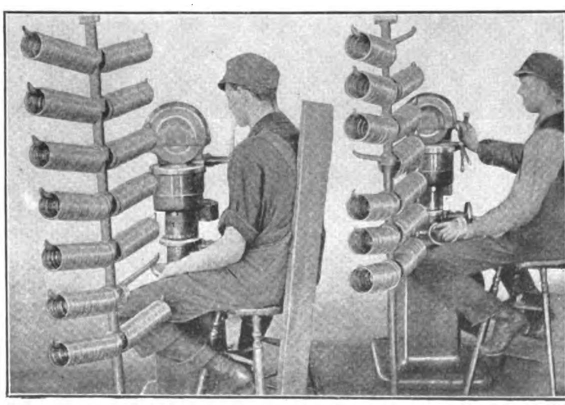

FIG. 18. FINISH-GRINDING SIDES. PRODUCTION: TWO OPERATORS, 1,200 EACH

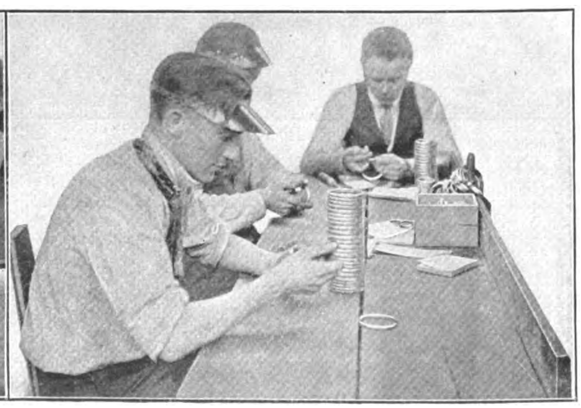

FIG. 19. FINAL INSPECTING, IN WHICH MICROMETERS ARE USED TO INSURE ACCURACY

The ring is compressed into a recess turned in an angle plate and then clamped in with a strap clamp as shown. The two cutters are then fed across.

The saddles are made of pressed metal, and are received as shown at the left in Fig. 13. The "backs"

operator, who grinds the other side and finishes it to size.

After the sides have been finish-ground, the rings are again placed in retaining sleeves and put on mandrels. They are then finish-ground to size on the outside diam-

eter, the saddles of course being in place as they were when the sides were ground. This grinding is practically the same as that for the rough circle grinding, so is not illustrated.

While several inspections have taken place during the progress of the rings through the shop, a final accurate inspection is given them by a group of special inspectors, as shown in Fig. 19. Micrometers are used, and the limits are very close. Many users specify just what radial wall pressure must be given by the rings they buy. To give them just what is called for, a special testing device is used. This is shown in Fig. 20. The ring to be tested is placed against the holder, with the slit to the left. The foot treadle is then pressed, bringing the upper plunger down on the ring. It is pressed down until the test indicator shows it to be the correct diameter, and then the radial pressure is read from the scale below.

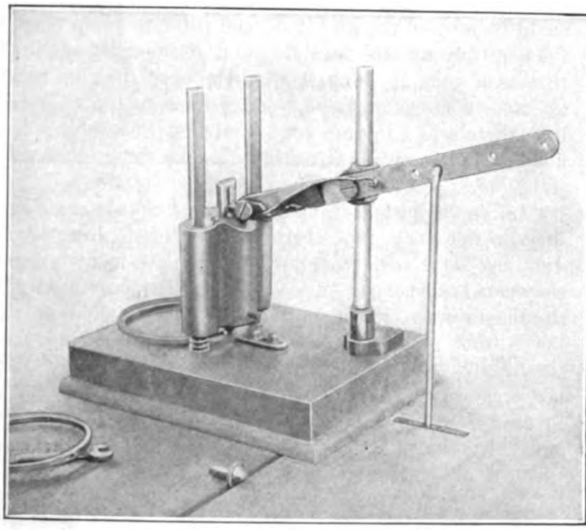

FIG. 21. TRADE-MARK STAMP

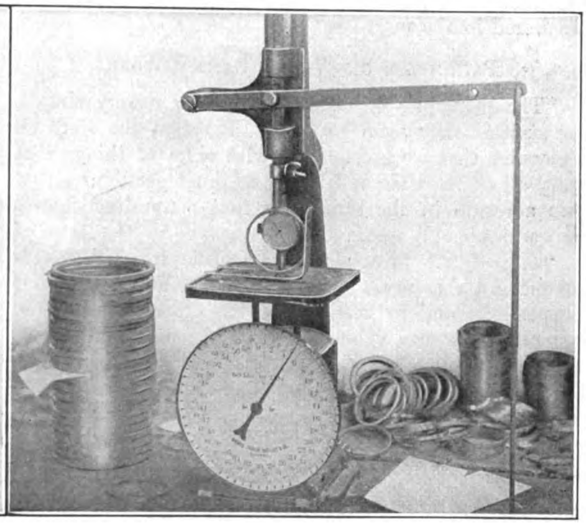

FIG. 20. DEVICE FOR TESTING RADIAL WALL PRESSURE

Small drop hammers like the one shown in Fig. 21 are used to stamp the trade mark on the sides of the rings. As a foot treadle under the bench is pressed down, the hammer head is raised until the dog slips out of the slot, when the hammer drops onto the ring below. As the treadle is released, the end comes down so that the dog or latch again engages the slotted piece on top of the hammer.

Sammy's Shop--Timekeeping for the Foreman

By W. Osborne

Fred W. Taylor started at the bottom of the ladder and reached the top. In doing this he did for the world a wonderful work that might be compared in some ways with the work done by scientists in other lines.

Lately we find on the market some gages that are known as Swedish gages. The workmanship on them astonishes mechanics.

Doctor Brashear does work that is recognized by the great societies of the world as of value in the advancement of human knowledge.

The child and the youth and the man are advised and urged to climb the ladder to the heights, but the fact remains that but few men are able to do the wonderful things.

Some practical fellow tried to analyze genius, and he said that "it is the *capacity* to take *infinite* pains."

An old joke told on a man who had struck oil and had sent a thick-headed boy to school was that when the boy had not made progress and the man was informed that the boy lacked "capacity" the rich man said, "Buy some for him." Old as this joke is, it always gets a laugh.

A friend who had dropped in was doing some "kicking" about the working of the latest cost-keeping system in his shop. He was general foreman.

"The job cost too much, all right. I am not denying that. The cost is away up, and that is wrong. But what are you going to do about it when it is not found out until it is all over but the funeral? Starting at the total and hunting back for the cost of the thing in detail, we found some steel priced wrong by a clerk, and we found too much time charged in by a man who has since quit. Sammy, it is lucky for you that you have a small shop that does not have to have much system. You can carry it all in your head, or most of it, anyway," he added, as he saw Sammy shake his head.

"If you had been able to get your people to look at the principle of the thing right, you should not have had so much trouble," said Sammy.

"What is the use of saying anything about principles?" asked the friend. "I have read articles written by Emerson and by Taylor and by Gantt and by Gilbreth and by Church and by others too numerous to mention, and they all seem all right when I am reading them; but when I try to get our principles and apply them to my own job, where am I? And when I look around and see the mess that a lot of folks make of it in trying to apply them, I feel sure that a lot of other fellows are in the same kind of a fix."

"Why don't you get up a system of your own that will just suit yourself?" Sammy asked in a way that carried doubt as to the answer.

"For at least two very good reasons: In the first place, my job is getting out the work; and in the second place, what is the use of another system gotten out by another man who does not know the principles on which he is trying to build? Now, honestly, Sammy, can you tell me the principles on which you run your own little private system?" queried the friend, as he settled back in his chair and looked at Sammy as though he knew he had asked a question that could only be answered in the negative.

Principles on Which Sammy Works

"The principles on which we work are very simple, or at least they seem so to us. Right at the start we recognize that we are dealing with a lot of things that vary all of the time and that we cannot get figures that are accurate in the same way that accounting figures are accurate.

"One of the principles of scientific investigation is to make a change on only one element at a time, if it is possible, and to keep all of the other elements the same. While you cannot do that if you call the complete job the thing under investigation, you can do it if you cut the jobs into small enough pieces and call each piece a thing under investigation.

"The machine-shop foreman knows that if the time that it takes to do a certain piece has not changed and that the wage that is paid the man is not changed, then the cost, as far as his share in it goes, has not changed.

"As I see it from the shop side of it, if you subdivide your jobs into operations and watch each operation so that the time on it does not increase, without any elaboration you know that the time on the completed machine has not increased. If the time on some operation does change, then the time on the completed machine changes; and by paying attention to those changes it is readily seen which way it has changed and how much.

"Just think of the position of your superintendent, or general foreman, or production boss, or whatever you may call the man who is held responsible for getting out the work in your shop. You put him into a shop with a lot of tools and a lot of men and give him a lot of material and supplies. He is not responsible for the shop's being built and filled as it is and very often is not given authority to rearrange the machines in the shop. The class of men that he has to use and the wages which they receive are often beyond his control. The material is not bought by him. In all fairness, how much should he be held responsible for? While the powers given to such men differ in different shops, yet as a general proposition all that he has it in his power to do is to have the operations performed on the machines best suited for them, by the men at hand who are best qualified to do the operations and in a time that is reasonable."

An Experience with Shop Burden

"I wish that you would come over to our shops and convert our cost department to that view. I was up on the carpet some time ago because some of the work was costing too much. The shop was running on short time. I had a chance to look after things closer than if we had been crowded with work and could not believe that I had been at fault. After they named pieces that they said cost more than they used to, I hunted things up and found that we were doing better on them than the average, but that it was the *burden* that had made the difference." The friend wiped the sweat from his face and continued. "How was I responsible for that burden and why, when they thought that something was wrong, did they jump onto me instead of onto some other one?"

"Don't you understand?" asked Sammy, laughing at his friend's earnestness. "You were there where you could be jumped on, and it seemed safer to jump on you than on anyone else in sight, and it must be admitted that as a general thing it would appear that, as being the man who got out the work, you were the only one that there was to jump on. You see, this subject has not received *scientific* investigation like some other subjects.

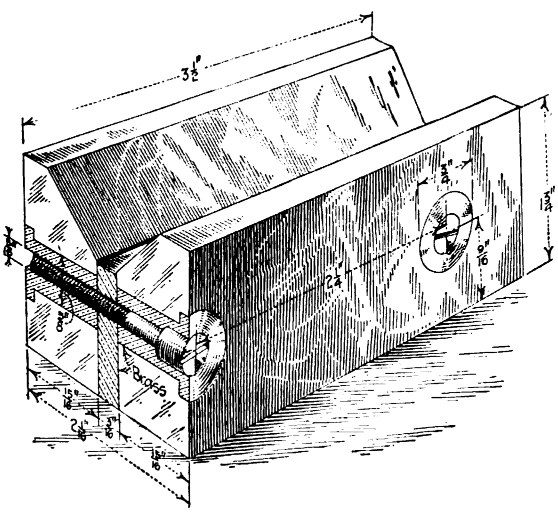
"As long as people think that their methods are right, they do not know that there is anything to investigate. Just the same, my friend, I believe that many a good shopman has lost out on cost-keeping evidence that put the blame where it did not belong. Dig right down to the bottom of these bonus systems and you find that the man has to get the work done in a *time*. The cost keeper should be able to show the shop from the time side in every system, and the shop be judged by that only, and after that the other things should be put on one by one and the rest of the organization judged."

"You want to look out a little, Sammy," said the visitor, as he started out. "You belong in some of the other places too. You may dodge a little trouble in the shop and get a lot more in the office. Mind about the fellow who said something about leaving familiar troubles for a lot that we can't size up until after we are in them."

V-Block for Magnetic Chuck

By J. C. Stuart

A very handy V-block to be used with the magnetic chuck on the surface grinder is shown herewith. Its



V-BLOCK FOR THE MAGNETIC CHUCK

usefulness on round work is readily seen. The block is ground all over after assembling.

Making 1-Lb. Cartridge Cases--II*

By Robert Mawson

SYNOPSIS—In this article are described the remaining tools and operations used in manufacturing the 1-lb. cartridge case. The illustrations give details of the punches, dies and other tools. Rates of production are also included. A novel method of packing is shown—a seamless casket that not only keeps the cases air-tight, thus preventing tarnish, but is also a convenient method of shipping.

After the cases have been trimmed to the 5½-in. length overall, they are washed in a tank containing "Carlsrhue" compound which has been heated to 210 deg. F. They are left in the liquid for about 1 min., afterward being rinsed in hot water, then in cold water. For the heading operation the shells are transferred to the

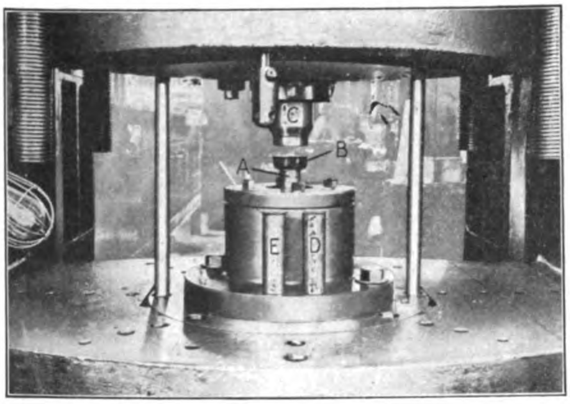


FIG. 45. HEADING THE SHELL

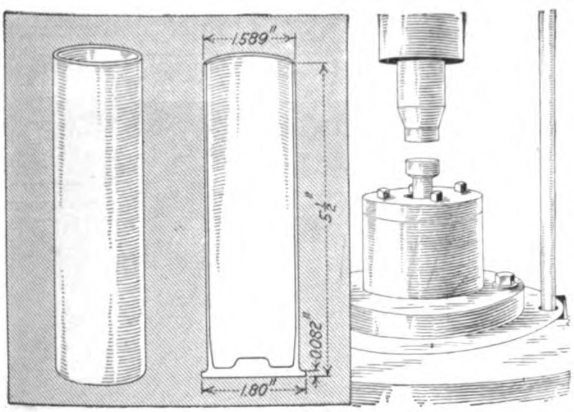

FIG. 46. OPERATION 17: HEADING
Machine Used—Bliss 12-in. stroke press.
Production—400 per hour.
References—Figs. 45 and 47.

machine seen in Fig. 45. The case is placed in the die *A*, and the bunter *B* is put on top of the shell. The punch *C* is then forced down onto the case and, pushing it down, forms the head. One of the shells before heading is illustrated at *D*, and after heading at *E*. The operation is shown in diagrammatical form in Fig. 46. Details of the punch, die, bolster, bunter and knock-out for the heading operation are given in Fig. 47.

The cases are washed in "Carlsrhue" compound, rinsed in hot water and afterward in cold water to remove the grease, as previously described. The cases are then annealed at the open end by dipping in saltpeter heated to about 760 deg. F., in which they remain for 2 min.

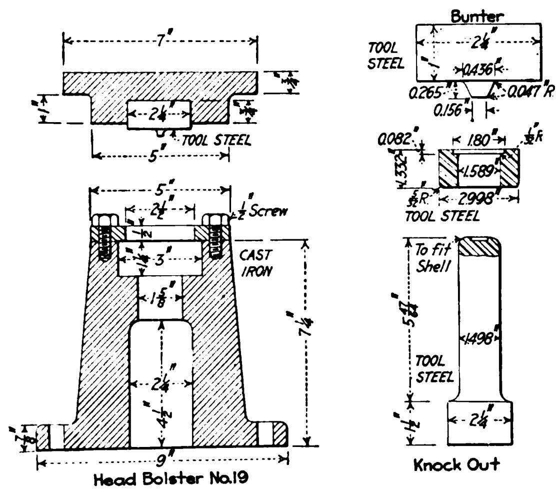

FIG. 47. DETAILS OF PUNCH, DIE, BOLSTER, BUNTER AND KNOCK-OUT FOR HEADING OPERATION

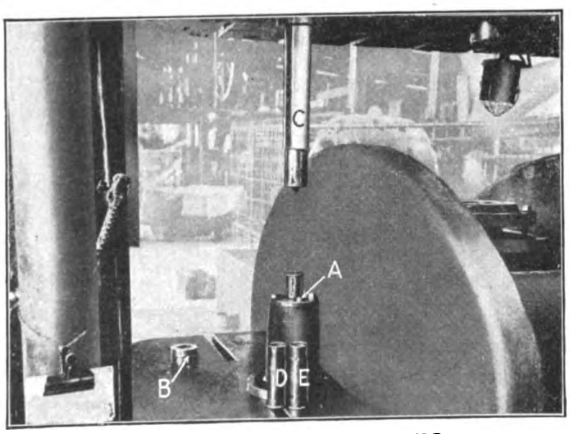

FIG. 48. TAPERING THE SHELL

The next operation is tapering, which is performed with the tools seen in Fig. 48. The case is slid into the die at *A* and the bunter *B* placed on the head. The punch *C* is fed down by the machine, and the case is forced into the die. As the die is made with a tapered surface, a similar contour is produced on the case. One of the shells before tapering is shown at *D*, and one after at *E*. The operation is given in diagrammatical form in Fig. 49. Details of the punch, bunter, die, bolster and knock-out for the tapering operation are shown in Fig. 50.

The shell is then taken to the small turret lathe, Fig. 51, the flange faced and turned to size and the primer

*Previous installment appeared on page 987.

hole roughed out. For this operation the shell is pushed into the chuck, being located against a stop surface. The handle A is pulled over. This operates the chuck, gripping it and holding the case so that it is revolved by the lathe. The tool B in the turret is pushed up by

the handle C, and the primer hole is rough-drilled and counterbored. The tool D machines the inside of the flange and its diameter to size.

The front post E carries two tools, one machining the outside surface of the flange and the other forming the radius in the flange. The tool posts are operated with the handle F. Stops are used on the turret slide and both tool posts, so that the correct dimensions may be obtained. The machining operation is shown in diagrammatical form in Fig. 52. Details of the tools for the operation are given in Fig. 53.

The case is transferred to the drilling machine, Fig. 54, and machined to length. The shell is placed on

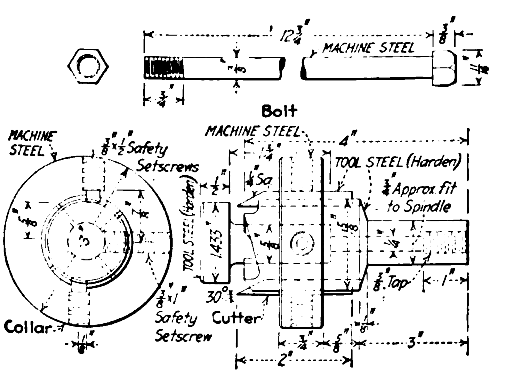

FIG. 57. CUTTER FOR FINISHING SHELL

Details of the clamp and holding fixture are given in Fig. 56, and the cutter in Fig. 57 is used for the machining operation. The inside of the primer hole is burred, as shown in diagrammatical form in Fig. 58. For this operation the case is held in a similar manner to that described for the preceding operation. The fixture and wooden clamp, Fig. 56, and the cutter, Fig. 59, do the machining.

The next operation—reaming the primer hole and forming the recess—is performed on the machine seen in Fig. 60. The shell is held on an arbor, as at *A*. The handle *B* enables the operator to hold and guide the case

under the tools. The primer hole is reamed and counterbored with the combination. The operation is shown in diagrammatical form in Fig. 61.

The combination tool and holding fixture for the machining is illustrated in Fig. 62. The cases are then conveyed to the inspection department for the final ex-

amination. A view of the inspection bench is given in Fig. 63. The various gages used are shown in detail in Fig. 64.

After the final inspection the cases that have been passed are stamped with the foot-operated press seen in Fig. 65. The case is placed on an arbor resting on a steel base, with the head carrying the stamp *A* raised. The operator removes his foot from the rope that holds up the trip, which then descends. The stamp thus marks the end of the cartridge case as desired.

The operation is shown in diagrammatical form in Fig. 66. The cartridge cases are washed to remove the grease and afterward packed ready for shipment. A novel method of shipping the cartridge cases is employed at this factory. The firm was originally in the business of manufacturing seamless steel caskets. These are now being used for the finished cartridge cases.

Each casket will hold 516 cases, which are placed in two trays. Attached to each tray is a board properly spaced to keep the cartridge cases from moving. The advantage of this method of packing is the ease with

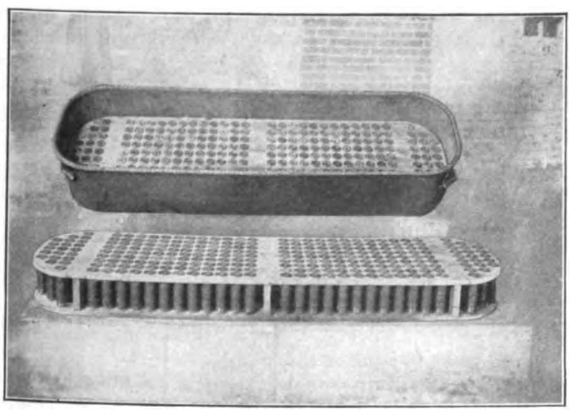

FIG. 67. PACKING CASE FOR CARTRIDGE CASES, WITH CAPACITY FOR 516 CASES

which the cases may be placed in the tray. Further, by removing the trays individually and turning them over, the cases will drop out straight and in a convenient position for forcing the steel projectile in position. Another advantage is that the shipper can readily see when the correct number has been put in, without the necessity of calculation.

One of these caskets is illustrated in Fig. 67 with the upper tray removed, so that the method of packing may be easily observed.

Packing Box for Shells

Packing boxes for shells have been made in almost every conceivable manner. Taking the 3-in. shell as an example, the practice of various manufacturers has been to place anywhere from four to twelve shells in a case. The way in which the boxes are made shows a similar variety, some being quite flimsy and others rather elaborate.

The International Steam Pump Co., Jeanesville Iron Works Plant, Hazleton, Penn., made an extensive study of the question, and the details of the type which it finally adopted are shown in Fig. 2. It will be seen that the box holds eight shells. The approximate weight of the loaded box is 129 lb.

FIG. 1. BOX PACKED WITH SHELLS

The boxes are marked consecutively, and a record is kept so that the actual number of shells exported in each case is known. The specifications for these packing boxes are as follows:

Box to be made of yellow-pine boxing lumber, free from knots and well seasoned; grids of white pine; battens and handle strips of yellow-pine. Sides, bottom, cover and ends to be preferably of single pieces; but, if not, material is to be tongued and grooved. Sides and ends to be jointed and battens to be worked over the joint at each corner. Battens to extend from bottom of box to top of cover, as shown, the upper and lower ends to be beveled to prevent splintering. Strips to be worked in between the battens to facilitate handling, as shown.

External dimensions of box over battens: Length, 10⅛ in.; breadth, 10¾ in.; height (including cover), 11⅞ in. Sides, tap ends and bottom to be of 1⅛ in. thickness net; to be surfaced on both sides. Internal dimensions of box: Length, 16⅛ in.; breadth, 8½ in.; depth, 9⅝ in.

Wood screws to be used in assembling bottom, sides and ends, as shown. In case bottom, side or end pieces are made of more than one piece, at least two wood screws shall be used at each end. All wood screws to be well countersunk; battens and handle strips to be securely nailed to box. No nail heads to enter box; or, if so, must be clinched flush with inner surface.

Grids: Two in number for each box, assembled as shown, and strips nailed together at each intersection, as shown. Nails to pass through both strips with ends clinched. The

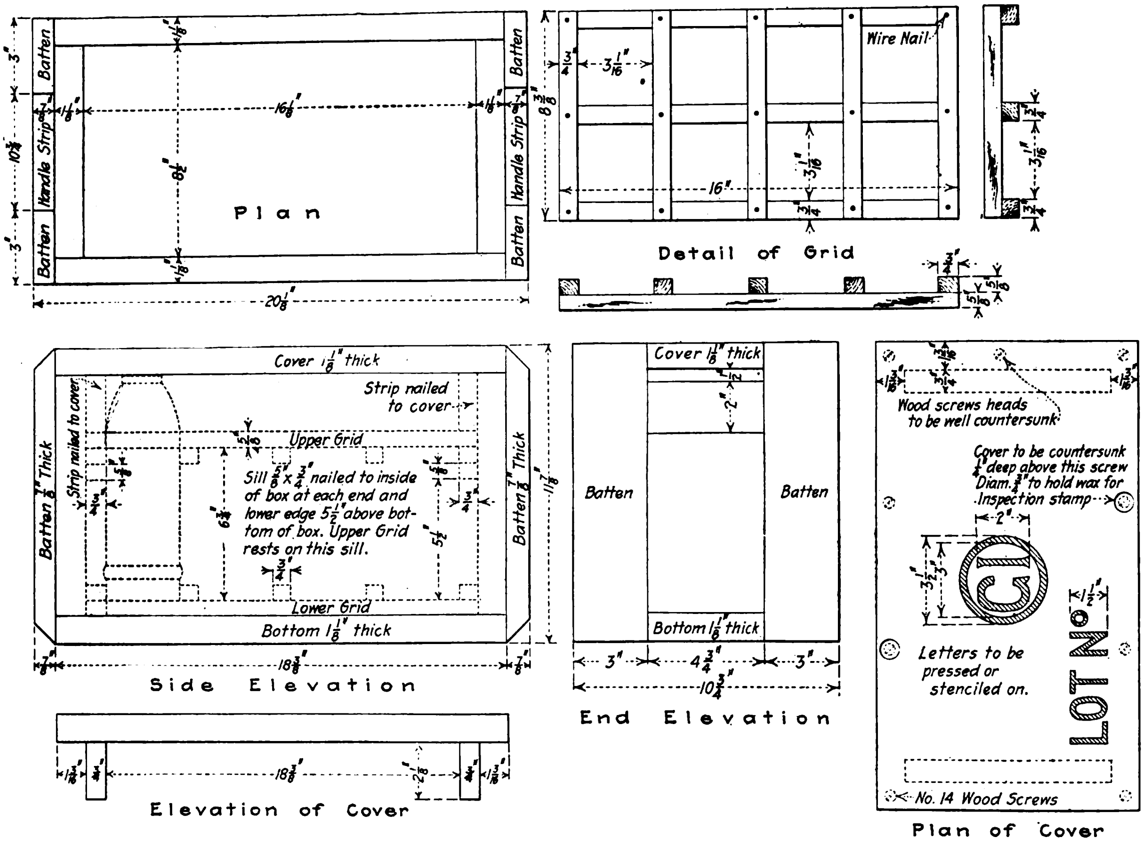

FIG. 2. DETAILS OF PACKING BOX FOR SHELLS

lower grid to be placed in bottom of box, as shown by dotted line, and nailed in place. The upper grid to rest on strips $\frac{5}{8}$x$\frac{3}{4}$ in., marked to ends of box inside, as shown. Lower edge of these strips to be $5\frac{1}{2}$ in. above bottom of box. To hold the upper grid securely in place, strips will be nailed to under side of cover, as shown by dotted lines on cover plan. Length of strips, $8\frac{3}{8}$ in.; width, $\frac{3}{4}$ in.; depth, $2\frac{5}{16}$ in.

Cover: The cover will be secured to box by 10 wood screws No. 14, spaced as shown. Then wood screws will be well countersunk. Two of these screws, shown on cover plan, will be countersunk somewhat more than $\frac{1}{4}$ in.; and above their heads will be worked a cylindrical countersink at least $\frac{1}{4}$ in. deep and of a diameter of $\frac{3}{4}$ in., to hold wax for the inspection stamp. On the cover will be stamped, pressed or stenciled the letter in black.

Bottom: The bottom is to be fastened to box in the same manner as the cover; heads of wood screws to be well countersunk. Sides and ends of the box will be fastened together with wood screws—heads countersunk—at least four screws to a joint. In cases where sides or end consist of more than one piece there shall be at least two wood screws at each end of each individual piece.

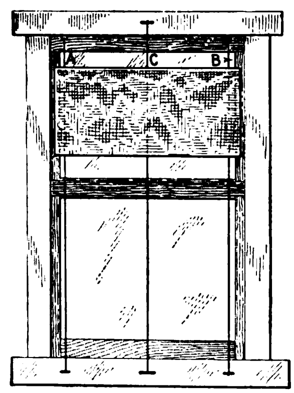
It will be seen from the detail that the shell rests in a grid at the bottom and in another which is attached to the cover. By this means the shells are held rigidly apart, preventing injury. A view of a box packed with shells, ready for screwing down the cover preparatory to shipment, is shown in Fig. 1. In this illustration may be seen the construction of the box and also the design of the grids on the cover.

Brittleness of Annealed Copper was made the subject of a paper at the annual convention of the American Electrochemical Society. The conclusion was drawn that brittleness of copper developed during heating in the process of manufacture and frequently ascribed to "burning" is in reality a deoxidation. With ordinary commercial copper, serious brittleness begins to appear at 400 deg. C. in dry hydrogen, at 600 deg. C. in wet hydrogen.

Light-Saving Window Blind

By J. H. Moore

What is more annoying to anyone working in an office than to have the sun beating directly on one while at work? Of course, to pull down the blind is the remedy, but good strong light is shut off before relief is experienced. The window blind shown in the accompanying illustration was made to overcome this defect and has proved to be a success.



LIGHT-SAVING WINDOW BLIND

It will be seen that the blind is of a narrow type, 14 in. wide, guided by the small wires *A* and *B* and pulled up or down by an endless cord *C*.

The Factory Transportation of Product and Materials*

By W. Rockwood Conover†

SYNOPSIS—The transportation of materials around a factory is a considerable item of expense. The author takes up the narrow-gage railroad, team, electric truck, elevating shop truck and mechanical conveyor, showing where each should be used and giving unit operating costs in some cases.

Transportation about large manufacturing plants constitutes an important item of expense. The old method of handling materials between shops by team and wagon is recognized as both slow and costly. Quick delivery of castings from foundry to machine shop, as well as the prompt unloading of incoming freight and its distribution to the various shops or departments, requires organization along systematic lines. Of equal importance are the rapid transfer of parts of apparatus on which labor is performed in more than one shop and the delivery of the finished product to the shipper.

The location of receiving and shipping departments as nearly central as possible reduces time and distance to the lowest practicable limit. A considerable percentage of bulky incoming goods, such as heavy castings and car lots of one kind of material, will of necessity and for economical reasons be unloaded at the platforms of the shops where they are to be used; but a large portion of the freight received at many manufacturing plants reaches the receiving building or central storehouse for tallying, storing and convenience of distribution.

The best results are uniformly obtained where the movement of materials is organized under the supervision of a superintendent or manager of transportation, whose function is to see to the prompt transfer of materials and shifting of trains in all parts of the plant. He should provide for the shifting of trains at the central receiving department so that the interval of delay is as short as possible. Under normal conditions the time required to make a shift should not exceed an average of 15 to 30 min. This is most important, as any delay at this point not only hinders the distribution of material to the shops, but also involves loss of time by the unloading gang.

The handling of broad-gage cars at the shipping department, and also of broad- and narrow-gage cars at the doors of shops or at platforms, so that materials or finished apparatus may be moved with facility and without delay, is equally important. The placing of cars at or within shops in large industrial plants is often a serious problem. Several departments frequently require cars for loading apparatus at the same time; and as often happens, the necessity for moving the material may be equally, or nearly equally, important in each case. Often the trackage at these shops is already occupied with cars containing incoming materials. Prompt action and judgment on the part of the superintendent of transportation are required to handle all these situations, which are constantly coming up, to the satisfaction of those who are being served.

It is necessary that the department foremen give their coöperation and direct the loading and unloading by the floor-labor gangs within their shops so that the work is accomplished in the shortest time practicable. Demurrage charges, which in many instances are unavoidable, are frequently the result of a lack of interest and attention on the part of those who should hold themselves responsible. In plants covering a large acreage, with numerous buildings, a division of the work into sections will render collection and distribution of materials much simpler, and the rapid movement of supplies will be greatly facilitated.

It is also advisable to provide some form of signal at the front of each shop to indicate to the train crews that service is desired in the hauling of either loaded or empty cars. The superintendent's office should be connected by telephone with all shops and departments, in order to afford quick notice of service required and also to provide for prompt action and remedy in the case of complaints or delays.

Careful attention should be given to the transfer of raw materials between the central receiving building and the various shops, as well as to the transfer of partly finished goods between departments, in order to avoid the delay and loss resulting from the delivery to wrong points of parts required for immediate production. This detail in frequent instances is of serious moment. In the hurry of business such materials may be thoughtlessly taken into stock, and only after long search and expenditure of time and labor are they located and returned to the proper department. The foremen in charge of the several departments should instruct each of their assistants to report immediately any articles received for which they have not already in possession the proper shop orders.

Moving Materials by Narrow-Gage Car System

The narrow-gage car system in general affords a rapid and satisfactory method of transportation about large plants for all classes of material, where the tonnage of individual pieces of apparatus or packages falls within appropriate limits. The adaptability of this system to short curves and narrow avenues, as well as to entering shops, renders it practicable and possible to reach nearly all points of the plant. It hardly need be stated that the electric-operated system is more practical than the steam operated and far more economical than the old method of transferring materials by team.

The cost per ton-movement, or per ton-haul, under the electrically operated system should not exceed 4½c. This cost should include the wages of the crews (motormen and helpers), cost of electric power for operating, repairs to motors or locomotives and cars, the necessary motor and car supplies, such as oils, etc., as well as the maintenance of tracks and overhead equipment. Among these items will necessarily also be included a charge for depreciation and also a fair proportion of the expense of superintendence of transportation. It does not include the time of loading and unloading cars, which labor is separate from transportation and is usually performed by the crane oper-

*Prepared for the author's forthcoming book on "Industrial Economics."

†Factory economist, General Electric Co.

ators and followers, the freight handlers in the receiving and shipping departments and by the floor-labor gangs of the several shops.

In certain lines of manufacture a large percentage of the material moved by the narrow-gage system will be heavy castings or packages of large size, which will be handled by crane operators and followers. The time occupied in loading and unloading this class of goods will be relatively less per ton than for lighter articles and smaller packages, which are loaded and unloaded by hand. It may be assumed therefore that the expense of handling will under normal conditions average approximately 2½c. per ton. The cost of this part of the labor should not exceed this figure, and the total expense of transportation, including loading and unloading, will therefore be 7c. per ton-haul under this system.

The average load per car for each haul should be between 5 and 7 tons, depending on the class of materials handled. When the pieces are castings, the average load will not be less than 5 tons; and on other goods it may reach an average of 7 tons.

Cost of Trucking by Team

The maintenance of trucking teams varies somewhat in different localities, necessarily affecting the cost per ton-haul of material under the old method. The average expense per year for operating a team and truck, including wages of teamster and helper, cost of feed, repairs and renewals to harness, wagons, shoeing, veterinary service, depreciation of wagons and trucks, etc., should not exceed $1,850, and under favorable circumstances may sum up as low as $1,600.

The class of materials usually hauled by team varies almost without limit, but in manufacturing plants in general throughout the country the average load will come within the limit of 2 tons. In plants of large acreage, 8 to 10 hauls per day may be adjudged a fair day's work for a team. The total distance traveled will average 8 to 10 mi. per day. If we consider the limit of 2 tons as the average of all hauls and 10 hauls as a day's work, the cost per ton-haul will be at least 27c., or nearly four times that by the narrow-gage electric system. It is reasonable to assume, however, that in the hauling of miscellaneous materials about factories by team the average weight of individual loads will more frequently approximate 1 ton to 1½ tons, and under these conditions the cost per ton-haul will be proportionately greater.

In comparing the cost of transportation of materials by the narrow-gage electric system with the old method by horse trucks I am considering plants covering an area not exceeding 100 to 125 acres in extent and am allowing for the operation of approximately 300 cars. It is evident in any such comparison that the acreage of the plant, number of miles of trackage, as well as number of cars operated, will materially affect the cost per ton-haul.

Economy of Electric Trucks

Electric trucks are valuable for rapid service about manufacturing plants for transferring goods from the receiving building to the various shops and for delivering material between shops as well as to the shipping building, express offices and railroad depots. These trucks will average at least 15 to 20 mi. total haul per day, not less than 10 tons of miscellaneous small pieces and a much greater tonnage of heavy articles for a day's work. They are specially adapted to the hauling of loads up to 3 tons' weight, where quick transfers and deliveries are essential.

The initial investment cost is lower than that of gasoline trucks, as is also the cost of operation and maintenance. Some types of storage batteries give a service of 30,000 to 40,000 mi.; and because of the fewer and simpler mechanical parts to get out of order, the amount spent for repairs to the truck is relatively lower. The cost of operation should include the wages of motorman and helper, expense of charging batteries, necessary repairs, supplies, etc., and this sum will vary considerably in different localities under different conditions as to cost of materials, service, etc.

The utility and economy of this method of transportation in comparison with trucking by team are self-evident in the rapidity and convenience with which materials can be transferred from point to point and in the reduced cost per ton-haul. Where a limited number of long hauls are made, the total mileage may be increased, while with short hauls the mileage will be greatly reduced, provided the average time of loading and unloading is approximately comparable in both instances. The character of materials hauled and the time required for loading and unloading will naturally affect the amount of business handled in any given period as regards both mileage and tonnage.

It is evident therefore that the manufacturer about to purchase an equipment of trucks should carefully consider the nature of the materials to be handled, the length of hauls and size of loads, as well as number of hauls it is desired to make per day, in order to select such capacities of trucks as will give the greatest efficiency and service at the lowest maintenance cost. This is an important point, which is apt to be overlooked in seeking a low initial expenditure. It has much to do with the final question as to whether the transfer of material by electrically operated trucks is economical and advantageous in the large degree that it should be.

Various Types of Hand Trucks

The equipment for plants manufacturing a variety of product, moving articles ranging in weight from very light to very heavy and making hauls of various lengths should consist of several or more trucks of varying capacity. It is obviously poor economy to operate large trucks of several tons' capacity for short, rapid hauls of light materials. In like manner the small-capacity trucks should not be used for the longer hauls of more or less heavy pieces.

The amount of service obtained in a day or a given period will necessarily depend in no small degree on the care and skill of the operator, and this, too, will affect in a large degree the life of the truck itself. In renewing or changing batteries the new battery should be put on the trucks that are making the longest mileage, and the partly worn-out batteries should be transferred to trucks making the shorter hauls and more frequent trips, where possible to do so. Some of the plates of batteries that have been removed can still be used in partly consumed batteries, thus greatly increasing their life and reducing the cost of maintenance in a very appreciable degree. The truck that receives the best care and attention, no less than the horse, will give the best economic results, other things being equal.

Hand elevating transfer trucks adapted to running beneath small platforms or boxes constructed upon lateral,

upright support pieces serve a valuable purpose in the moving of materials from one machine to another between operations or in transferring parts about shop floors or from one building to another. The trucks are so constructed that they can be pushed or backed beneath the platform, box or crate by the floor laborer. When the trucks are in proper position beneath the load, lowering the truck handle to its proper position for hauling the material to its destination lifts the load sufficiently to clear the shop floor. The manufacturers claim a marked saving in floor-labor expense by the use of these trucks, and their claim appears fully justified. Under this system the machine operator piles his castings or materials upon the platform or puts them in the box or crate, thus eliminating entirely the necessity of repeated rehandling by the shop-labor gang. Under normal conditions a laborer with one truck should serve not less than 80 to 100 platforms, and frequently one truck will take care of the handling of over 100. The number will depend upon the frequency with which the materials have to be moved between machines or from one section of the department or factory to another.

Accumulating trucks also perform a valuable service in the collection and transfer of materials. They are constructed with two or three tiers of trays on which to place all the parts for assembling a given piece or type of apparatus. These trucks are operated between the stockrooms and the assembly floor.

Material stands, composed of two or more trays for holding productive work, facilitate the moving and handling of articles between machine tools and benches or various parts of the shop floor. They should be constructed with wheels or casters, so that they can be transferred from one point to another with ease by the labor gang.

Advantages of Mechanical Conveyors

The economical advantage of mechanical conveyors is so generally known that no statement need be made in their favor. Where certain kinds of material are to be transferred at short intervals or continuously across open areas or courtways between the various shops or departments of a plant, the utility of the different types of belt or bucket conveyors has long ago been demonstrated. In the work of unloading coal, sand, cement or other supplies of a similar nature received in bulk or carload and transferred to storage piles or storage houses the conveyors are of especial value. Moving platforms can be installed in some factories for conveying materials between different points or along machine and assembly floors, thus eliminating the necessity of employing large floor-labor gangs.

Electric locomotives on the broad-gage system are of great worth in making hauls to and from sidings and in cases where definite, regular classes or kinds of productive goods are to be handled. For short shifts, also, or the placing of a limited number of cars and for the handling of irregular classes of work under special and difficult conditions the electric locomotives are not only giving excellent service, but are proving fully equal, if not superior, to the steam locomotive.

The wage of operating crews, it is apparent, should approximate closely the scale of wage on the narrow-gage electric system, while the expense for repairs in the present state of perfection in electric-locomotive building is relatively small, as is also the cost of supplies.

This type of broad-gage motive power is coming more and more into general use in large plants as the manufacturer is becoming more familiar with its economic advantages and utility.

In any system of transportation the providing of proper facilities for loading and unloading will be recognized as a most important factor in obtaining adequate or satisfactory results. Platforms should be placed at convenient locations near shops, storage sheds, warehouses and casting floors, so that materials may be transferred into and out of cars with as little handling as possible. Inclined approaches to platforms that are raised above the ground or floor level of the shop are a necessity where the materials have to be conveyed to or from the platforms by trucks.

The means for loading and unloading should also include a sufficient equipment of cranes of such types as are adapted to the specific conditions, in order to handle materials rapidly and save delay or stoppage in the movement of either cars or electric trucks. Overhead cranes of ample tonnage capacity are essential in conveying heavy castings or other bulky articles from point to point along the storage platforms or open storage areas, whenever it is desirable to pile these materials in stock until required for use.

Repairs to Rolling Stock

Repairs to locomotives and cars deserve consideration. These repairs generally constitute a large item of expense. Short curves, often required in laying the tracks around buildings and in carrying the shorter contributing lines into narrow areaways or shops, are frequently a source of trouble and accident. The placing of empty flats or lightly loaded cars between cars loaded with heavy machinery or castings should be avoided as far as possible. Even where reasonable care is exercised by the engineer or motorman in the handling of his trains, the shunting of the cars together in the rapid movement of goods often results in derailment of those lightly loaded and sometimes of those carrying heavy freight. These accidents not infrequently occur at switches and cause damage either to the cars themselves or to the tracks, with the consequent delay in the movement of materials and also the cost of repairs. The danger of breakage to fragile pieces that are being transported from one point to another has also to be considered.

While a considerable percentage of the renewals is the necessary result of legitimate wear and tear, the handling of the rolling stock should receive careful supervision and the cost of upkeep be brought within the lowest limit consistent with the demands of rapid service. The building devoted to the housing of locomotives should be of sufficient size to provide for a repair department, with necessary trackage and pits and a proper equipment of tools to keep in first-class shape both the locomotives and the broad-gage as well as narrow-gage cars. Sufficient space should be provided for carrying a stock of parts in such a convenient way that repairs can be rapidly made with facility and economy. The office of the superintendent of transportation is located in this building, which makes it possible for him to see that the work of keeping the transportation equipment in good condition progresses properly and without delay to the service.

The maintenance of broad- and narrow-gage tracks, especially during the winter months, also adds to the cost of transportation. The melting snow from roofs,

together with that which falls on the surface, at times renders difficult and costly the work of keeping clear the tracks through narrow areaways between buildings. In those narrow places the tracks should be raised above the surface as far as practicable, the shop roofs should be provided with suitable gutters, and a series of catchbasins and drains should be installed to carry off the surplus water. The expenditure necessary for these improvements will be found in most instances to represent a good investment.

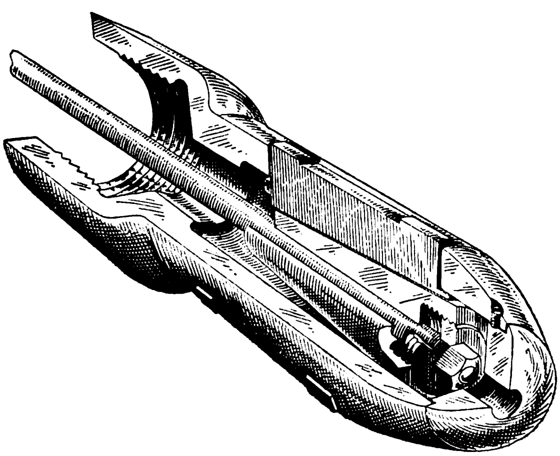
In a majority of plants there is a greater or less extent of trackage that lies below the adjacent ground surface and that is in consequence a constant source of expense. Even during the summer months the wash of earth and refuse caused by heavy rains makes it necessary that the switches receive frequent and special care. The labor of clearing these tracks is usually charged in with repairs or other yard expense, and by reason of this fact the matter does not commonly receive the full amount of attention that the subject merits. A moderate outlay for betterments will frequently save the manufacturer no inconsiderable yearly loss.

Expanding Mandrel for High-Explosive Shells

By John S. Watts

The illustration shows a mandrel devised for holding the British 4.5-in. high-explosive shell while rough-turning the body and finishing the base to thickness. This mandrel has been used successfully for over six months.

The chuck is operated by a 6-in. double-acting air cylinder attached to a ¾-in. rod passing through the hollow lathe spindle. It could of course be tightened



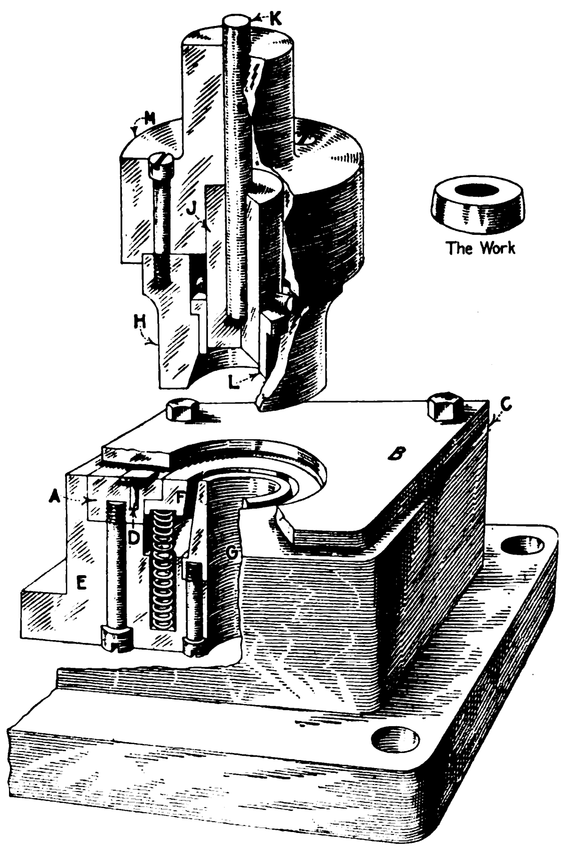
EXPANDING MANDREL FOR SHELLS

up by means of a handwheel on the back end of the lathe spindle, where compressed air is not available. The screwed bushing in the end of the sliding piston is to make it easy to adjust the position of the sliding piston longitudinally without having to disconnect the air cylinder. The mandrel itself is threaded to screw on the nose of the lathe spindle, so as to make the overhang as short as possible.

One-Operation Punch and Die for Making Ferrules

By Nicholas Ernzer

The tool shown was designed for making ferrules in one operation. The stock, which is 0.015 in. thick, is passed over the die *A*, under stripper *B* and held against the gage *C* at the back side of the die and also against the stop pin *D*. The stripper and gage are held down by two $\frac{5}{16}$-in. fillister-head screws tapped into the die, which is sunk into the shoe *E* and held by three $\frac{5}{16}$-in. fillister-head screws. It has a shoulder that keeps the spring pad *F* in place, allowing it to move down when a ferrule is being formed over the piercing die *G*, which



COMPOUND-TYPE PUNCH AND DIE FOR MAKING FERRULES

permits the slug to pass down through the bolster. The element *G* is sunk into the shoe *E* with three $\frac{3}{16}$-in. fillister-head screws to hold it in.

As the operation of cutting and forming with *H* is nearly completed, the punch *J* pierces the ⅞-in. hole in the ferrule and carries it to the top of the stroke, and the knock-out pin *K* strips it off the punch. With the press tilted back, the ferrule will readily drop free of the die.

The knock-out pin runs loose inside of the piercing punch, which is slotted to allow the $\frac{3}{16}$-in. pin to come in contact with the collar *L*, which in turn moves up when the ferrule is being formed and therefore does not cause any interference.

Tools Used for Machining Automobile Details

Editorial Correspondence

SYNOPSIS—In this article are shown some of the jigs and methods used in machining automobile details. The machine for boring the crank case is fitted with stops against which the fixture is placed in boring the crankshaft and camshaft holes. A planing machine that has been converted into a miller is also interesting. A miller on which an attachment is fitted for keyseating is worth noticing. Some aluminum jig templets are illustrated.

The Dile Motor Car Co., Reading, Penn., has a number of interesting tools for machining automobile details. In Fig. 1 is shown the machine for boring the bearings in the crank cases. The casting is located by dowels that fit into holes previously machined. It is held securely with clamps.

The head carrying the boring tools is fed down and also revolved by gearing driven by the pulley *A*. The table-feeding mechanism may be thrown out of mesh by a clutch operated with the handle *B*. The heads may then be fed by hand by the handwheel *C*. It will be seen that two stops *D* are fastened on the table. The fixture holding the casting is pushed against the stop, as shown, and against the stop *E* for machining the main and cam bearings respectively. The average time for boring the crank case is 30 min.

In Fig. 2 is a planer that has been changed over and is used as a miller. The casting is fastened on the table,

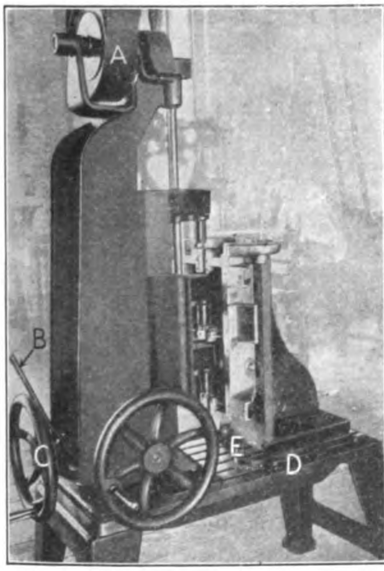


FIG. 1. MACHINING CRANK CASES

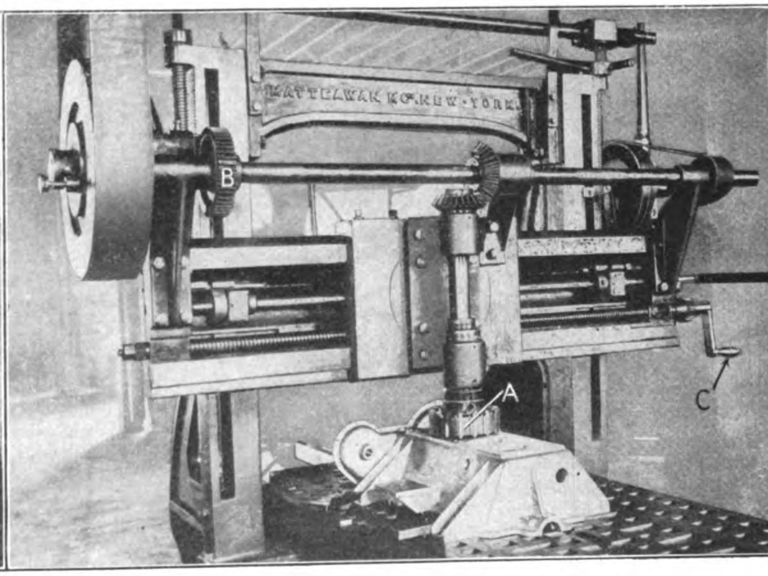

FIG. 2. PLANER CONVERTED INTO A MILLER

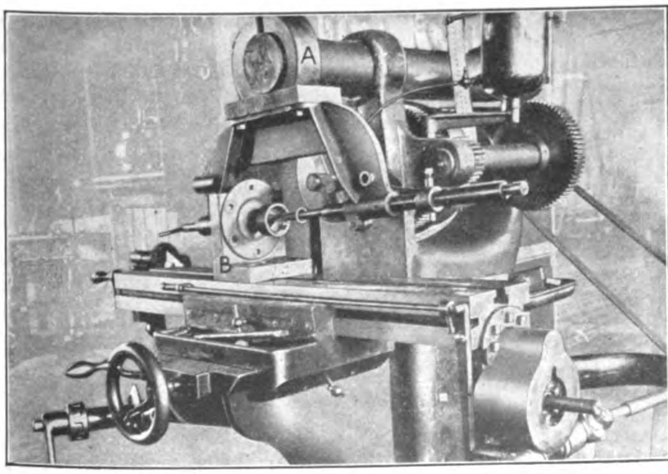

FIG. 3. KEYSEATING ATTACHMENT

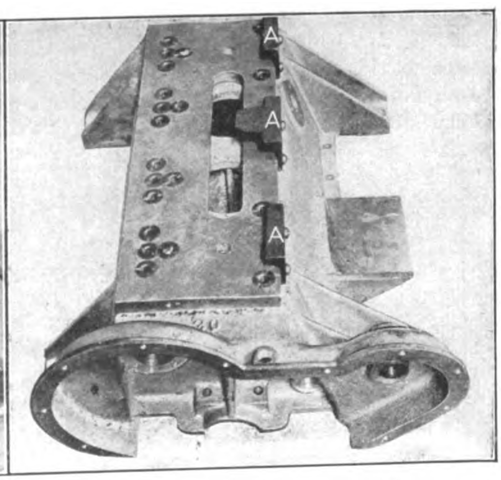

FIG. 4. JIG FOR CRANK CASE

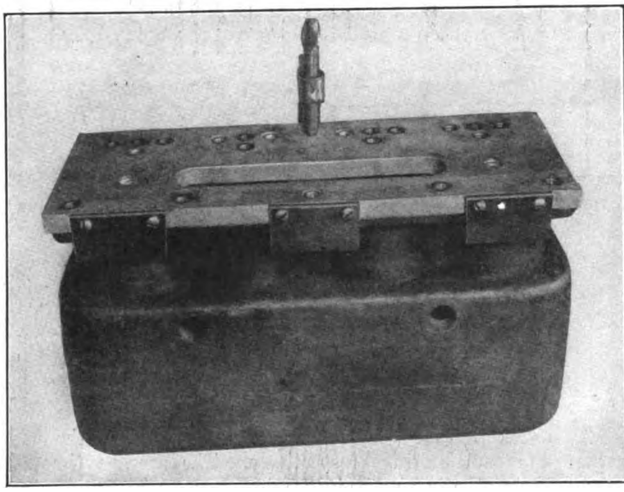

FIG. 5. DRILLING THE CYLINDER

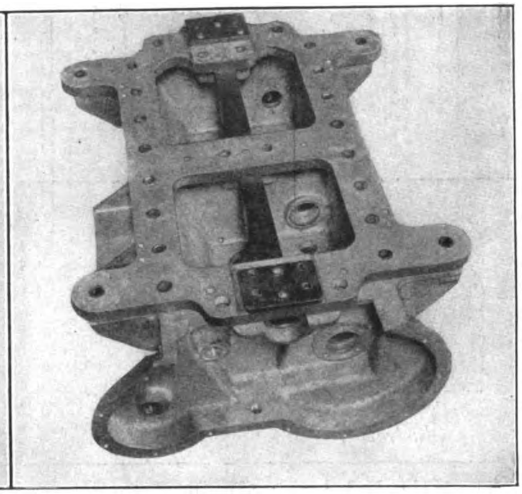

FIG. 6. DRILLING JOINT SIDE OF CASE

as shown. The milling cutter *A* is driven through bevel gears. The adjustment of the cutter is obtained through screws and nuts, the motion being received through the gearing *B*. The head is moved across the table with the handle *C* operating the screw shown.

In Fig. 3 is an attachment fitted to a miller for cutting keyways. It is fastened to the arm at *A*. The part to be machined—in this case a rear hub—is attached to a fixture *B* on the table. The bar *C*, carrying the correct size of tool, is held as shown. As the table carrying the part is fed along, the tool machines the desired keyway. An advantage of this method is that it machines not only straight splines, but also keyways with any degree of taper. To obtain a tapered spline, it is only necessary to slide around the attachment at *A* to the desired angle.

In Fig. 4 may be seen the jig templet used in drilling the cylinder side of the crank. The templet is placed on the milled casting, being located by the ears *A*. The various holes are then drilled through the bushings shown. The jig is reversed as in Fig. 5 for drilling the cylinder, being located again by the stop plates. With this method the holes will be in alignment with each other in the crank case and cylinder.

The jig for drilling the joint side of the crank case is seen in Fig. 6. The jig is located by pads that are set into the bored hole of the crank case. A rather novel feature of these jigs is the fact that aluminum is used in their construction. This material has been found satisfactory and has also the advantage of being much lighter than regular cast iron.

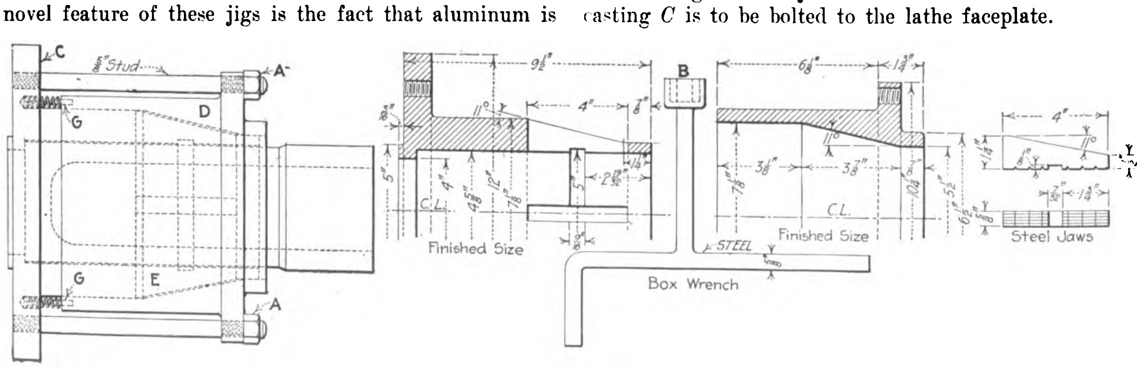
Nonslipping Shell Chuck

By H. P. Hoag

One of the annoying things in most shell shops is the slipping of shells as they are held for boring in the standard lathe chucks. After a careful investigation of this problem the chuck in the illustration was brought out. It is giving entire satisfaction on the 4.5-in. shell, as it will hold without slipping against the heaviest cut either on a rough or a finished shell. Not only is this chuck cheap to make and maintain, but it is quick to operate—simply tighten two hexagonal nuts *A* with the crank wrench *B*.

The chuck body *C* and the outer movable sleeve *D* are both made of close-grained cast iron. The hardened tool-steel jaws *E* are held in place by a clock spring. Should the chuck get out of alignment, it is only necessary to remove one of the jaws and grind off the back enough to make the work come true again. Two small springs *G*, between the main casting and the outer sleeves, keep the sleeve back against the tightening nuts.

One interesting feature of this chuck is that, should the back of the jaws wear into the movable sleeve *D*, two more holes may be drilled in the flange of the sleeve, which is thus moved around by the tightening studs to a new bearing for the jaws. It will be noticed that the casting *C* is to be bolted to the lathe faceplate.



DETAILS OF A NONSLIPPING SHELL CHUCK FOR USE IN THE LATHE

Letters from Practical Men

Progression Punch and Die

The illustration Fig. 1 shows a die that should be of interest to readers. The die and punch are shown at *A*, a section of the strip with the operations in sequence at *D* and three of the finished blanks at *C*. These blanks consist of a flanged cup with three perforations. The flange is $1\frac{3}{8}$ in. in diameter. The cup is $\frac{3}{4}$ in. in diameter by $\frac{1}{2}$ in. deep and is perforated with an $\frac{11}{32}$-in. hole. The flange has two $\frac{3}{16}$-in. perforations. In Fig. 2 is shown the lower half disassembled.

Promoting the Right Man

I think that the methods used by various managers and superintendents in selecting department heads and substitutes would be of value, if related in the *American Machinist*. I am prompted to write this after seeing several what I call foolish promotions. These were generally made because the man advanced was thrown more in contact with the superintendent, or man with promoting power, than the rest of the men. My own experiences strengthen this belief.

I was working in a shop on a large special job that took about five months. It was not complicated work that needed any special skill; any good tool maker could have done it. It was out of the ordinary for this shop, so that the superintendent took particular interest in it and stopped very often to look it over and talk to me, which he was not in the habit of doing with the rest of the men. He therefore got better acquainted with me than with anyone else in the room.

Shortly after this job was finished, it became necessary to put on a night force in the machine room. This force consisted of 100 men, all but three or four of them green at our work. I was made general foreman of this force, over the heads of men who had been there several years longer than I and who had considerably more experience, some of them having been foremen in other places.

I received this promotion because, when the superintendent found himself up against it for a foreman in a hurry, his thoughts turned to me, simply because of our recent conversations over that special job. Of all the men in the toolroom I was foremost in his mind. There were several men better fitted for the position than I, right there before his eyes, but he could not see them. I have seen so many instances of this same kind of promotion that I am convinced it is often done.

When I was a young man, I worked beside a fellow whom I will call Tom. He was an exceptionally good man and I was very chummy with him, though he was ten years my senior. I worked beside him for about five years and knew his good and bad points.

About two years after leaving this shop I found myself superintendent of a shop and in need of a foreman. My first thoughts were of Tom. I had a foreman who was recommended by Tom's superintendent, but it became necessary to dispense with him. So I went up to Tom's superintendent and said, "I have come to swap you a poor foreman for a good tool maker." "Do you think Tom would make a better foreman than Frank?" he asked. "I know he would," I replied; "if you had worked beside him for five years, as I did, you would think differently. He does not move fast, but every move he makes counts. When he starts somewhere, he knows where he is going and what he is going for."

I saw Tom and put my proposition up to him. He was glad to see that I had remembered him, but he wanted a week to think it over. At the end of a week he told me that he would not be able to take up my proposition, as he had been made general inspector of the whole plant. He had been working there eight or nine years, and no notice had been taken of him until I opened the superintendent's eyes. How many managers and superintendents have a Tom in their shops? They should

dig him out instead of picking men on the impulse of the moment. Have them picked out in advance.

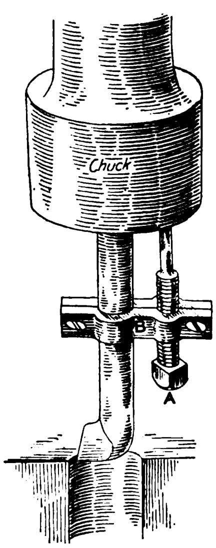
It makes discord among the other workmen to see a man less competent than themselves put over them, and discord never makes for the efficiency that we are all striving for. There is always some feeling, no matter who is chosen; but if he is a capable man, the others soon forget their jealousy. If he is not a capable man, he himself will not allow them to forget it, because he will always be doing or saying something to remind them of it.

Hartford, Conn. J. C. STUART.

Offset Boring Tool for Miller

The accompanying illustration shows a method of making an attachment for use with an offset boring tool. In using offset boring tools it is best to have them under tension. The setscrew *A* is for obtaining this effect and for springing the tool so that it will bore to size. This tool has proved of value in shops not equipped with offset boring tools. The clamp *B* can be made to take in various sizes of tools.

THOMAS W. R. MCCABE.
Waterbury, Conn.

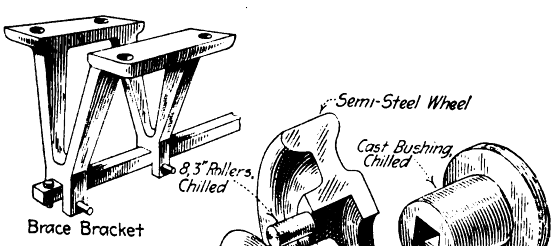


OFFSET BORING TOOL FOR THE MILLER

Truck Wheel with Chilled Roller Bearings

In the sketch are shown a heavy-duty truck wheel and bracket designed for rolling-mill purposes. Artistic designs and "mike" measurements are seldom considered in the make-up of trucks used around a rolling mill. A loose easy fit, a pound of grease—where an ounce would do—and a strong, able-bodied chunk of corned beef and cabbage pulling at the handle, his body bent at 45 deg. to the ground, answer all requirements in make and motive power in a rolling-mill truck.

The life of the truck is short, because the laborer at the handle thinks from his neck down. If there is one chance in a hundred to put the truck out of commission, he is Johnny on the spot.



TRUCK WHEEL WITH CHILLED ROLLER BEARINGS

The wheel here shown is of the underhung or caster type. There is very little machine work on the parts. The wheel itself, which is of cast semisteel, is assembled as it comes from the foundry. A dry-sand core is used to make the center hole, better results being obtained when the hole is made in the core. The roller bearings are of chilled cast iron 3 in. in diameter and 5 in. long. The axle bushing, or sleeve, is of chilled cast iron, having a cored hole to receive the square axle. The retainer washer is of cast semisteel.

The cast-steel bracket, of Y-design, with plenty of spread where it bolts to the truck, is fork shaped, to fit down over the square axle, and has holes to receive bolts. As compared with some of the trucks now in use, it is easy rolling for the man in the mill.

Kenosha, Wis. M. E. DUGGAN.

Valve-Seat Facing Tool

Fig. 2 illustrates a self-contained facing tool which we had occasion to use in facing off the valve seat of a T-head cylinder, as shown in Fig. 1.

The valve-seat boss of this cylinder was ¼ in. larger than the port plug hole through which the facing tool must go, so it was necessary to have some way of expanding the tool after it had gone through the port hole. Accordingly, we constructed the tool shown. The shank *A* is made to pilot into the port hole before it is tapped. This shank has a T-slot cut across it and the tool holder *B* fitted into it, so as to slide back and forth. A groove is cut in the tool holder to hold a spring, and a pin *G* is set in as a stop. The stop *F* holds the spring in place. It in turn holds the tool holder even with one side of the shank.

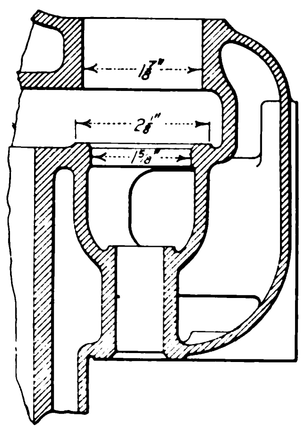


FIG. 1. THE VALVE SEAT

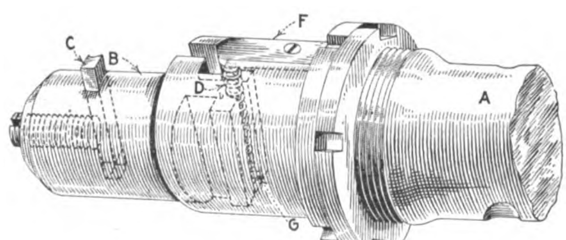

FIG. 2. THE FACING TOOL

The tool *C* is set into the holder so that the end comes even with the opposite side of the shank. In operation the tool passes through the port hole; and as the taper on the tool holder strikes the taper of the valve seat, it centralizes the tool holder, taking the tool out over the surface to be faced. When the tool is withdrawn, the

holder springs back and is able to come up through the port hole. The notched stop nuts determine the height of the boss. We have used this tool with great successs at the Rochester Motors Co. FRED F. BOWEN.

Rochester, N. Y.

An Oxyacetylene Job at Sea

A novel job was recently done at sea on board a vessel belonging to the United States Navy. A bucket on a direct-connected air pump was broken beyond repair. For temporary purposes an auxiliary feed pump was connected to the channel way, after the links to the disabled air pump had been disconnected. With the assistance of an oxyacetylene outfit an emergency bucket was made as follows:

The bore of the cylinder was 30 in. To allow for machining and for the removal of iron oxide two circular steel plates 32 in. in diameter were cut. The top plate, $\frac{3}{4}$ in. thick, carried the spiders for the valves and the lower $\frac{1}{2}$ in. plate. A templet was then cut out of sheet tin, embracing one-fifth of the top of the bucket, which included a nest of three valves. The sections to be cut out were then accurately laid off from the templet to the $\frac{3}{4}$-in. plate and center-punched for easy burning. To allow for the free passage of the water, circles 5 in. in diameter were cut out in the lower plate.

In all, about 25 ft. of cutting was done in the $\frac{3}{4}$-in. plate and about 19 ft. in the $\frac{1}{2}$-in. plate. The work was completed in less than three hours, while the vessel was steaming in the trough of a heavy ground swell.

To make the bucket of the proper depth, a distance or filling piece of teak was placed between the top and bot-

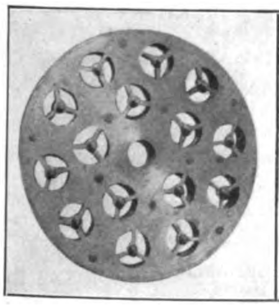

FIG. 1. TOP OF VALVE BUCKET

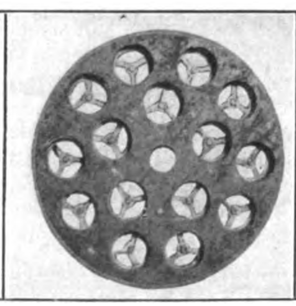

FIG. 2. BOTTOM OF THE BUCKET

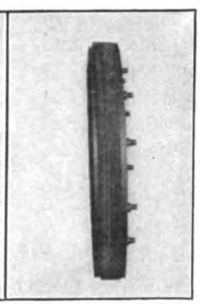

FIG. 3. SIDE VIEW OF BUCKET

tom plates, which were then riveted together, as the use of bolts and nuts was not considered desirable.

The bucket was chucked in the lathe and bored to suit the taper of the rod, which was then forced home. Next the rod was swung between centers and a cut taken across the upper surface of the top plate to provide a true surface for the valves to seat against.

The outer surfaces of the top and bottom plates were then turned down $\frac{3}{16}$ in. smaller than the bore of the cylinder of the pump. The teak filling, or distance piece, was then turned down $\frac{1}{16}$ in. smaller than the bore of the cylinder, water grooves being also cut to obviate the use of soft packing. Teak was employed as a distance piece on account of its oily nature, which makes it impervious to water.

Fig. 1 shows the top of the bucket, with the rod, valves and springs removed to illustrate the design used in cutting out the $\frac{5}{8}$-in. plate so as to provide a spider for carrying the studs, springs and valves.

Fig. 2 illustrates the bottom of the bucket, while Fig. 3 is a side view showing the teak filling piece. Although the bucket has not as yet been put into actual service, it is being held as a spare part for an emergency. It was completed and made ready for service in less time than it would have taken to make a pattern of it for casting. F. A. SAAR.

U. S. S. "Prometheus."

Grinding-Wheel Experiences

One of the few points that grinding-wheel experts are agreed upon is that different kinds of work require different kinds of grinding wheels. Carried to its logical conclusion, this also means that, although work may be similar in character, if the material is different the grinding wheels may also have to vary to get the best results. Not only may we have to change the grade and grain, but we may have to use wheels made up from another basic material.

To the average shopman who takes only a superficial interest in grinding wheels this shifting from one make of wheel to another presents many difficulties, and for this reason changes are not as frequent sometimes as results warrant. What we really need is to have the wheel makers give in their catalogs a close comparison between their own wheels and those of their competitors for a given class of work. There is, to the best of my knowledge, no catalog of grinding wheels in existence that gives a table showing the comparative hardness of the wheels. Such a policy might be advertising the product of other manufacturers, yet for the purpose of changing over from one make to another it is essential that the various hardnesses should be known.

Possibly the wheel makers may point out that close comparisons are out of the question. But suppose a would-be customer asked a manufacturer to supply a wheel for work that had been done previously by a competitor's wheel of a certain grain and grade. Would the manufacturer say he could not form any comparison or would he send a wheel? We rather think he would send a wheel. This being so, then the information is really available and could be tabulated. Failing this comparative list, we want more data about the wheels in service; that is, users should tell us of wheels that have been successful on certain classes of work and should detail the conditions. A statement of some of the writer's experiences with the grinding wheels in an ordnance factory may be of interest and possibly may also draw out the grinding-wheel experiences of other readers of the *American Machinist*.

The wheels in both the foundry and the forge were 24x3 by 2-in. hole and were set on ordinary floor stands. The peripheral speed of these wheels was between 5,000 and 5,500 ft. For the rough work that they had to do—snagging castings, forgings, etc.—probably the best all-round wheels that came under observation were those made by the Sterling Emery Wheel Co. They were corundum wheels—grain 24, grade *Q*, and grain 20, grade *P*.

Another corundum wheel that did well was a Sundale grain 24, grade *O*. A batch of wheels supplied by the Pike Manufacturing Co.—grain 16/14, grade *Q*—gave excellent service. A remarkable point about these large wheels for rough work was that none of the wheels made from artificial abrasives did nearly as well as those made from corundum. This showing we believe to be due to the greater toughness of the natural abrasive. Probably the best wheel of artificial abrasive tried on this group was Alundum grain 24, grade *O*, and grain 20, grade *P*.

The last experience to be mentioned on this size of wheel was with some sent in by the American Emery Wheel Co. They were corundum wheels. For the foundry, wheels of grain 14, grade *P*, performed well. For the forge, grain 2820, grade *Q*, was tried, but the wheels were found to be too hard until the peripheral speed was dropped to about 4,800, when they cut very well. However, this wheel—grain 2820, grade *Q*—was found later to give excellent service in grinding the edges of bullet-proof plate.

Another large wheel in this factory was a 24x2 by 5-in. hole, for use on Norton cylindrical grinders. On this class of work the artificial abrasives seem to have the field to themselves. The writer cannot remember a case where corundum was as good as Alundum or Aloxite for grinding on precision work—that is, where both work and wheel are rigid.

The best Norton wheels in this group were Alundum 24 combination grain, grades *K* and *L*—with a preference for grain 46, grade *L*, when working on nickel steel. These grades were also found to do good work on the larger Landis machines where the wheels were 18x1½ by 8-in. hole. For the smaller Landis wheels 14x1 by 5-in. hole Alundum 24 combination, grades *K*, *L* and *M*, were good, but the best wheels of this size for general service on steel were Aloxite grain 60, grade *P*, and Aloxite grain 403, grade *O*.

For grinding ball-race rings (flat faces) with this size of wheel on the Landis, Alundum grain 3860, Grade *J*, and grain 3846, grade *J*, gave splendid results. For cast iron and manganese bronze, Carbolite wheels, made by the American Emery Wheel Co., grain 60, grade *K*, and grain 46, grade *L*, were good.

On surface grinders we had fine results from Alundum grain 2846, grade *G*, on steel. Other good wheels were Alundum grain 24 combination, grades *F*, *G* and *H*; and for cast iron, Carbolite grain 46, grade *G*. These wheels were 12x2 by 5.9-in. hole and ran, according to material operated on, between 4,000 ft. for mild steel and 3,200 ft. for certain hardened cast steels and cast iron. It should be noticed that these low speeds are essential for good work on the surface grinder.

When a good finish is desired, preference may be given to a straight-grit wheel of fine grain (such as 46 or 60 grain), but a fine-grit wheel should be softer in grade than a combination grit, to work equally well. Fine finish here is more a question of correctly truing the wheel than of choosing a finer grain. The writer tried Aloxite wheels for surface grinding in this size of wheel and found that grain 60, grade *T*, was better than grain 403, grade *S*, for steel.

Both wheels, however, were a trifle too hard to be efficient when running as low as 3,200 ft. per min.

A large number of wheels 10x1½ by 1-in. hole were used in this plant on floor grinders for the convenience of the workmen in touching up their tools. Alundum wheels grain 36, grade *O*, and corundum wheels made by the American Emery Wheel Co., of similar grain and grade, did well. Another good wheel that was selected subsequently after a comparative trial was grain 46, grade 4½ *W*, a corundum silicate wheel made by the American Emery Wheel Co.

For toolroom work generally, Norton's Alundum wheels were used, grain 46 in grades *L* and *K*, also grain 60 in grades *K* and *J*.

For internal grinding the wheels ranged from ½ to 1½ in. in diameter. Alundum grain 60, grade *J*, and grain 46, grade *K*, were good on steel. Satisfactory work was also done by some American Emery Wheel Co.'s corundum silicate wheels grain 60, grade 2 *W*, and grain 46, grade 2½ *W*.

A good many wheels were provided for saw sharpening. For gulleting, Alundum wheels 8x⅛ by $3\frac{9}{16}$-in. hole were used, grain 80, grade 5½ elastic. For topping the saws a somewhat wider and softer wheel was selected—Alundum 8x¼ by $3\frac{9}{16}$-in. hole, grain 60, grade 5 elastic. We also tried an Alundum vitrified wheel for topping. This was grain 60 and grade *P*. While this wheel did very well for a short time, it eventually broke; and undoubtedly for this class of work no vitrified wheel of this size should be thinner than ⅜ in.

Similar-sized wheels made from corundum by the American Emery Wheel Co. were: For gulleting, grain 80, grade 5½ *E*; and for topping, grain 60, grade 5½ *E*. For saw sharpening there was little choice among the different makes of wheel. In closing these notes it might be mentioned that, except where definitely stated otherwise, all the wheels referred to were made by the vitrifying process.

WALTER G. GROOCOCK.

Guilford, England.

Pitch of Broach Teeth

The making of broaches has been more or less on the cut-and-try plan. In order to systematize it a little the following data have been compiled.

The table herewith gives the pitch of broach teeth for work varying from ¼ in. to 12 in. in length. These pitches are calculated from the formula $P = \sqrt{L} \times 0.35$,

PITCH OF BROACH TEETH

Length of Hole in Work, In.	Theoretical, In.	Practical, In.	Length of Hole in Work, In.	Theoretical, In.	Practical, In.
¼	0.175	3/16	4	0.700	11/16
⅜	0.214	7/32	4¼	0.721	23/32
½	0.247	¼	4½	0.742	¾
⅝	0.277	9/32	4¾	0.763	¾
¾	0.303	5/16	5	0.782	25/32
⅞	0.327	5/16	5¼	0.802	13/16
1	0.350	11/32	5½	0.820	13/16
1⅛	0.371	⅜	5¾	0.839	27/32
1¼	0.391	13/32	6	0.857	27/32
1⅜	0.410	13/32	6½	0.892	29/32
1½	0.429	7/16	7	0.926	15/16
1⅝	0.445	7/16	7½	0.959	31/32
1¾	0.463	15/32	8	0.990	1
1⅞	0.479	15/32	8½	1.020	1 1/32
2	0.495	½	9	1.050	1 1/16
2¼	0.525	17/32	9½	1.079	1 3/32
2½	0.553	9/16	10	1.106	1 3/32
2¾	0.580	19/32	10½	1.134	1⅛
3	0.606	19/32	11	1.160	1 5/32
3¼	0.631	⅝	11½	1.187	1 3/16
3½	0.655	21/32	12	1.212	1 7/32
3¾	0.678	11/16			

where *P* equals the pitch and *L* the length of the work. The table shows the theoretical length and the nearest fractional dimension to which it is practical to make broach teeth.

R. C. HAYNES.

Hudson, Mass.

Discussion of Previous Question

Cutting Off Steel in the Lathe

Gustave A. Remacle, on page 294, while pointing out the most elementary fact—the setting of the tool—in parting still leaves plenty of opportunities for chatter, which he claims to have overcome.

Leaving out the setting of the tool and the coolant used, chatter may be due to width of tool, distance of tool from chuck, state of headstock bearings and, last, but by no means least, the manner in which the tool is held.

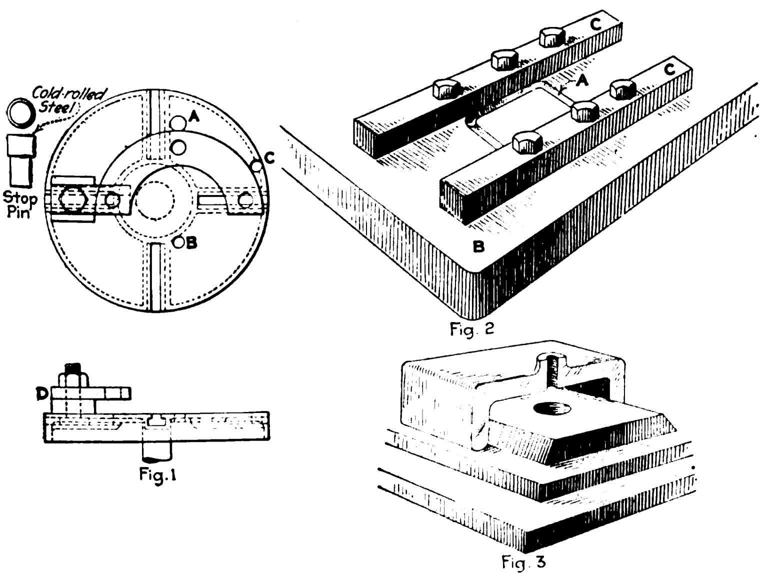
The typical American tool post is not an ideal one to use in parting, particularly for large-diameter stock, and the larger the diameter the greater the inclination of even the best-behaved tool post of this type to allow the tool to dig and chatter.

John H. Van Deventer demonstrated this point admirably in his "Small-Shop Lathe Lecture—No. 1," with two sketches and descriptions to suit. The first, "A rakish appearance, but no good for work," is applicable to the case in point; and the second, "Give a dog teeth if you want him to bite," shows a four-way tool box with the double grip on each tool. JOHN C. WELLS.

Dumfries, Scotland.

Simplifying Drilling Operations

Mr. Hampson's article in the *American Machinist*, on page 558, reminds me of some similar work I have come across. In view of the heavy rush of business at the present time we would hardly go to the expense of designing a special jig, even if it should be a very simple one. On the other hand, because of the present rush, the quick methods herein described may be particularly interesting.



SIMPLIFYING DRILLING OPERATIONS

In any of these methods accuracy is not attempted, but for general approximate work at high speed they answer exceptionally well.

In Fig. 1 is illustrated a brass locomotive-hub liner to be drilled and countersunk, as shown at one of the end holes. The various operations for producing this work in quantities are as follows: First, the liners are brought to the bench, and the location of each hole is center-punched through a plate jig. A very heavy punch mark will enable the hole to be drilled close enough. After being center-punched the liners are taken to the drilling machine, in the table of which the three holes *A*, *B* and *C* have been drilled.

The rig *D* is merely a leaf jig, so to speak, and is made up of a leaf and a drilled block secured to the drill-press table by a ¾-in. bolt. A stop pin is provided, as shown. The distance between the under side of the leaf and the table is about $\frac{1}{32}$ in. greater than the thickness of the liner, to allow for possible burrs, etc.

One end of the liner is slipped under the leaf, the ¾-in. drill is brought down into the punch mark and the first hole drilled, the stop pin being placed in the hole *A*. All the liners are so drilled at this setting. Then the stop pin is placed in the hole *B*, and the center hole in all the liners is drilled. Last, the stop pin is placed in hole *C*, and the last hole is drilled in all the liners. The stop pin, as its name indicates, is merely a stop. The leaf is to prevent the liner from breaking the drill by running up on it under the excessively heavy feed.

After the drilling, another machine does the countersinking, using a stop for depth, of course. Since the center-punch mark is used to locate the hole, some might think the leaf a superfluity; but the fact remains that the quickest and the safest way (for the operator) is shown here.

In Fig. 2 is shown a jig for the same purpose as Mr. Hampson's jig, but in design, construction and operation this one can hardly be excelled for simplicity. The work is kept from turning by the two straps *C* and is centered by the shallow grooves *A*. As a piece is drilled it is readily pushed out of the way and another piece placed in position. To save the drill-press table, the grooves are cut in a separate plate *B*, and to this plate the straps *C* are secured by the six capscrews shown, the whole then being bolted, or clamped, to the drill-press table.

In Fig. 3 is illustrated a device of some use on brass, or where the stock is pretty close to size. Good brass or malleable castings can often be drilled to advantage in this way. The slightly tapered square boss on the base plate fits loosely inside the casting, as shown—within 0.005 in.

or so. If the central chip hole is lined up with the drill-press spindle, this will center the work; but the edges of the piece being drilled must be set down firmly, all around on the shoulder, as illustrated, in order to bring the hole straight as well as central. Accuracy, of course, cannot be attained by any of these methods; but where production is the first essential or where the hole is to be used for an arbor for further machining, etc., these methods will deliver the production.

Besides, it ought to start a good line of thought as to how much can profitably be done in using jigs of this sort in the absence of jigs or fixtures of a better kind. It seems to me that a great deal of duplicate work might be handled, especially where the quantity has seemed too small to justify the designing and building of more elaborate jigs. These built-up jigs are also capable of considerable elaboration. J. B. MURPHY.

Plainfield, N. J.

Practical Points in Operating the Suggestion Plan

I have observed of late that managers are reviewing the suggestion system from a more practical viewpoint than formerly. [See pages 78, 212, 561, 692 and 815, Vol. 44, also editorial, page 1001, Vol. 43.] The profit from the specific suggestion has been the prime reason for its adoption in the past, and only few employers recognize the possible coöperation and loyalty features that are the outgrowth of a suggestion plan.

Not long since a boastful employer said, "Why, I have over 3,000 men working for me." I answered, "Yes, I know that, but how many men have you working *with* you?" He nearly lost his breath for a second and finally concluded by saying, "We supposed they all were, but I doubt it."

There is no other system that will assist to determine who is or who is not loyal to a company quite as efficiently as a well-managed suggestion plan. It may be well to quote a few lines from my letter published in the *American Machinist* some eight years ago: "The objects of the suggestion box are justice, coöperation and profit."

The first requisite of such a system should be a man at the head of the department who merits the confidence of both employer and employee; one who can readily detect evil motives in the suggestion or criticism and put a stop to it.

Second, give to each communication a thorough investigation and, if rejected, give evidence to the suggestor of the impracticability of the considered project that will convince him beyond any doubt of the company's square policy.

Third, if the suggestion is accepted and the employer installs it, the suggestor should receive a compensation in proportion to its value, the value being based upon a percentage of the net saving to the company for a stated period of time, dating from the actual application of the suggestion.

It is important that all three of these requirements be complied with, and any fundamental change in them will bring the plan into disfavor and failure. Every breakdown of the suggestion system to date is attributable to modifications affecting these points.

In the last six years I have observed several suggestion systems dry up and blow away because one or more of these requisites was disregarded. In one case shop politics, through the incompetency of the committee in charge of the suggestion department, caused the help to distrust the motive of the company, and valuable suggestions stopped coming in. The men with a pull got good pay for suggesting, and the honest fellow got left.

There is hardly a man who has worked at a trade 10 years that cannot recall at least one incident where his suggestion was taken to the management as an idea of the foreman or superintendent, thereby giving credit to one to whom it did not belong. The disloyalty among employees that such methods develop is incalculable, and the right system will obviate it.

The suggestion system brings an employee in close touch with the other elements of the business, such as cost of supervision, maintenance, interest, taxes, insurance, depreciation, etc., which the regular day's work salary, piecework and bonus methods fail to do. The employee hears of these items; but when he sees the percentage that must be added to the cost of bringing his suggestion into actual service, an appreciation of the true condition dawns upon and impresses the suggestor as no other method will.

The suggestion system should be divided into three divisions—observation, criticism and suggestion. An employee may be able to observe and report things of interest that should be investigated and corrected, and yet he may be unable to criticize or offer a suggestion to correct the condition observed. However, such a person should receive credit for the discovery made. It is also true that a person may observe and criticize a condition that escaped the notice of persons competent to suggest a remedy. Such a person should receive a greater credit than the one who only observed the condition. While the person who observed the condition, criticized it and offered an accepted suggestion to remedy it should receive credit in proportion to the service rendered. Such grading of merits, whether it is represented or recorded by merit points or dollars, will surely enlist all intelligent employees to work with the employer and create an enthusiasm and loyalty that will increase efficiency beyond the calculation of the most enthusiastic advocate of the system.

The employee's record card should show the number of suggestions offered or accepted every month. If an employee presents suggestions every month, we know he is trying to do his best for the company, although the idea may not be very valuable. The suggestion system properly operated is one of the best methods of discrimination between the loyal and disloyal employee ever devised, as well as a profitable department in any business, wherever it is installed; but justice must prevail. Shop politics must be eliminated and the management must not expect results too quickly. It is a process that should be developed on practical lines, and each branch of the business will present a different problem to solve. The greatest handicap under which such a system is installed is the general lack of confidence on the part of the employees. When they are convinced that absolute fairness will prevail, the inherent advantages of the plan assure success. CYRUS F. RAYMOND.

Akron, Ohio.

Progress of Industrial Education

The advance of industrial progress has been so rapid during the past decade that the corresponding advance in the environment and ideals surrounding technical education, as depicted in the new buildings of the Massachusetts Institute of Technology described on page ??? of this issue, seems in harmony with the trend of events. It is no doubt the most finished and impressive example of architecture that has ever been applied to such a purpose.

Quite a contrast is presented when one considers the disadvantages under which were developed many of the great names which have been handed down to us for their discoveries in science and engineering. Newton, Watt, Maudsley and Sweet had no palatial buildings in which to ferret out the secrets of nature; neither had they laboratories containing all manner of appliances, nor had they instructors who were ready at hand to fill in the missing gaps in their supply of information.

And yet the names of Newton, Watt, Maudsley and Sweet come down to us and will outlive most of the names of those who acquire their knowledge and training in modern educational institutes.

Just as an unexplored country develops rugged pioneers who surpass in physical hardihood, so the unexplored regions of knowledge of years ago developed intellects of a magnitude that is hard to equal under present conditions of uniformity and standardization.

For the purposes of present-day civilization the modern scheme is no doubt a better one. Science has to a large extent taken the place of inspiration, and it is better for us to have a large number of scientists and engineers trained in a comparatively standardized manner as they are, than to look, probably in vain, for the reappearance of inspired genius of bygone days. And it must be said that the Massachusetts Institute of Technology has an enviable reputation in turning out those equipped to advance industrial and scientific progress.

Do not be discouraged, however, if it has not been, or will not be, your lot to acquire information amid such beautiful and impressive surroundings. Remember that, while a man can acquire knowledge within a building, he must learn to reason within his own head.

And what a contrast it will be for some of the coming Tech grads when they leave these marble halls for the unæsthetic shops and factories which will be the scene of their life work!

What Is the Economical Length of Workday?

One of the effects of the widespread making of munitions seems likely to be the general shortening of hours in the machine shops of the country, even though this change may not be accomplished immediately. It has already taken place in many localities; and if history is to repeat itself, as it generally does, this shorter day will become more common rather than give way to the old schedule.

As a sidelight on the situation it is interesting to mention the experience of a number of shops that are now running two shifts in order to get out their production of shells in the shortest possible time. The usual method seems to be to run a 10-hr. day shift and a 13-hr. night shift. For while this seems like an unequal and almost absurd division, it has some advantages. The night man might just as well go to work at 6 as to wait an hour or so. On the other hand, there is nothing to be gained by quitting much before 7 in the morning. The advantage is that it keeps the automatics going and gives them a longer day on the payroll. But the economy of it is quite another matter.

In most of the shops we know that are running in this way the management is more than satisfied if the night shift of 13 hr. gets an output equal to that of the day shift of 10 hr., giving an hourly production much below the day rate. In other words, the extra 3 hours can be called entirely nonproductive.

To just what extent this policy can be carried economically remains to be seen. It cannot be forecasted with any certainty. But it does show that many of our predictions about the bad economical effects of the shorter workday have not come true. The difference in the quality and in the quantity of light between the day and night shifts will account for some of the difference, but there can be no question as to a man's ability to work at a higher efficiency during a short period. And it is really the efficiency that counts, for on this depends the output of the machines.

The worst problem in all such cases is to know what is best to do when an output is demanded which is larger than can be had in 8 hr., but which does not require working two shifts. Overtime work is a makeshift, to be put into practice only in emergencies; yet the organizing of a night force is more of a problem than many realize. The shorter hours seem to produce a normal day's work as well as the longer day we formerly thought necessary, and the old 60-hr. week has a diminishing number of advocates. If we remember that in most cases efficiency is in getting the most work out of a machine rather than the greatest amount of physical labor, it may change the solution of the problem to some extent.

Storing the Capacity for Making Ammunition

There is much discussion as to the relative merits of government and private plants for the making of arms and ammunition. Unfortunately, this talking is too often done by those who know little or nothing of actual manufacturing conditions. There are many sides to the question, all of them more or less debatable; but the best solution depends largely upon conditions.

Huge government plants tie up vast amounts of capital, which would be—fortunately, in most ways—idle most of the time. This sum represents a far larger expenditure than would appeal to the average taxpayer, although it is barely possible that such procedure might be cheaper in the end. Then too, the average arsenal is not run as economically as might be desired, although no one has been able to show just why it is impossible to run a government shop so as to produce goods at fair prices; in fact, we have some very good examples of this possibility in our own country.

On the other hand, the arsenals, with a large surplus capacity, might serve as a balance wheel to prevent exorbitant prices being charged for munitions supplied by private concerns. In fact, arsenals should go farther than this and act, in a measure, as experimental shops to find the best way of making such products as they are likely to be called on to make in large quantities. They should determine the best methods for varying shop conditions, determine fair standard times in which the work can be done and use these results as a basis for prices of contracts that may be let at any time.

While no arsenal in this or in any other country has carried on such investigation to any extent or is in position to do it at the present time, we in the United States have an excellent opportunity to secure these data for future use. It is this consideration, in fact, that has prompted the *American Machinist* to publish in detail so many of the operations of shell making in the various shops. These data, backed up by the experience of our own arsenals and of the best private plants, give us a basis for standardizing times that should prove of great value in future work.

It has been suggested that the machinery of some of the large munition plants that have been especially equipped for the purpose might well be purchased by the Government and stored for future use. Such machines should be bought at a nominal price, because they are practically of junk value, owing to their being very special and having no market value except to the Government, and because they have already earned a large profit on the investment. Any attempt to secure high prices for such machines would tend to prevent their purchase, as it would give the best of arguments to those who contend that all preparedness is for the personal profit of those with material to sell.

With enough special equipment stored in various arsenals, or in special shops that can be secured at low cost in inland cities, to turn out 100,000 shells a day in case of need and with a skeleton organization that understands the machines we are a long way on the road to practical preparedness at a very low cost. It must be remembered that the question of labor hardly enters into this problem, as most of the special machines have been designed especially so as to be readily handled by men who never saw a machine shop before.

An equipment of this kind, slushed to prevent rusting, could be maintained at a low cost and could be put into commission at short notice. While it might not supply all that would be needed, it would give an excellent foundation and enable at least a good beginning to be made.

This is very different from the proposition to purchase gages and fixtures which might be altered to suit our conditions. The machines are made for just this work and only need sets of tools to suit our type of shells. With gages, on the other hand, almost all would require alteration that would be as costly as new gages in many cases. Making new gages in large numbers, however, so as to have them ready, would be of real value.

We must not overlook the fact that there is a deep-rooted conviction (which unfortunately has too good a foundation in some cases) that personal profit is behind much of the urging for preparedness. Any plan that succeeds must disarm this suspicion. The best way of accomplishing such an end is to show that national service, as well as personal profit, is being considered.

Russian Credits--Shipping Documents for Russia

As Russia is principally an agricultural country, sales there are made on credits maturing with the yearly harvests. In seasons when crops have been poor it has been found necessary to extend some credits to the following year. Russians, as a class, are disposed to guard their financial standing jealously, although the fact that bankruptcy is not uncommon there shows the necessity for care in obtaining credit information.

Our leading bankers have made arrangements to handle Russian-American business direct, and through branches established in Russia they will find means to finance the loans required there after assuring themselves of the soundness of the security offered. Now is the time for American manufacturers to get the information they require, connect with agents, provide catalogs, etc., so that they will be able to place their sales campaign in full swing at the end of the war.

The economic similarity between Russia and the United States indicates that soon after the war Russia may place a still higher tariff wall around her territory, so that manufacturers intending seriously to enter that market should keep in mind the examples of two successful American firms, one manufacturing agricultural machinery, the other sewing machines. Both these concerns do a world-wide business and both found it advantageous to establish branch factories in Russia. There the heavier pieces of their machines are made, the lighter and more complicated parts being imported from the United States.

In shipments made from the United States to Russia the documents may be in English. The Department of Commerce in Washington, D. C., publishes the consular regulations covering shipments in all countries. Machine builders may also turn over all these details to commission merchants or forwarding agents who specialize on Russian shipments. Correspondence from Russia should be answered in the language in which the inquiry is written.

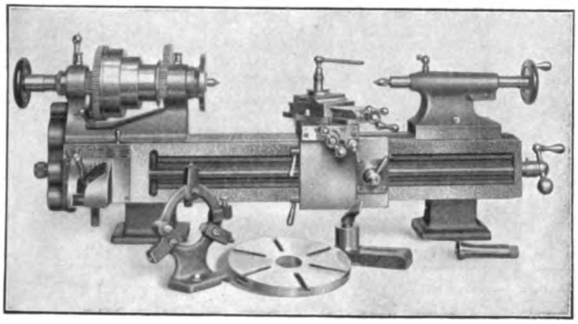
During the war the principal exports to Russia have consisted of munitions of war, while the imports from Russia have greatly decreased, owing to laws prohibiting the export of certain articles and to the high freights demanded.

This has caused the ruble, ordinarily worth 61½c., to drop to about 31c., but the normal rate of exchange will doubtless be reached as soon as peace is declared. This may not be far off, and American machine builders should start now a comprehensive campaign to extend their interest in Russian markets.

Shop Equipment News

Bench Precision Lathe

The precision lathe illustrated represents a recent product of Walter H. Wade, 311 Atlantic Ave., Boston, Mass. Although this lathe is designed primarily for



BENCH PRECISION LATHE
Swing, 8½ in.; distance between centers, 24 in.

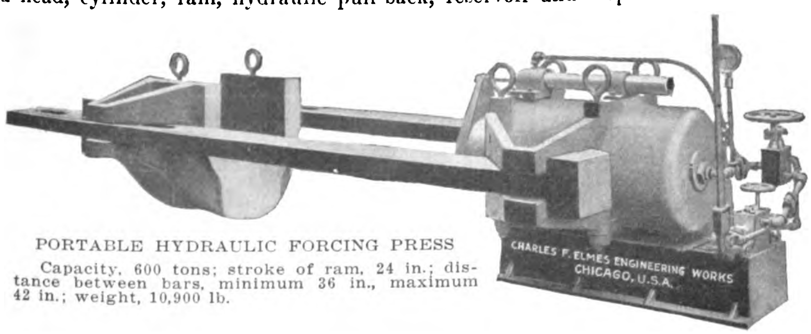
toolroom use, the various classes of accurate work for which it is especially adapted will come to mind.

The bearings are of tool steel, hardened and ground. The lathe is equipped with a quick-change gear box through which threads from 12 to 120 per in. can be cut.

The machine is furnished with either two-speed and reverse treadle countershaft or friction countershaft.

Portable Horizontal Hydraulic Forcing Press

The press shown was designed for pressing shafts out of dredge tumblers, rolls, large gears, etc. It consists of a head, cylinder, ram, hydraulic pull-back, reservoir and



PORTABLE HYDRAULIC FORCING PRESS
Capacity, 600 tons; stroke of ram, 24 in.; distance between bars, minimum 36 in., maximum 42 in.; weight, 10,900 lb.

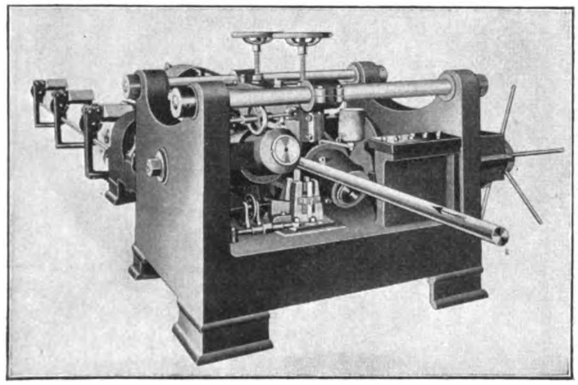
double-plunger hand pump with valves and hydraulic gage, all self-contained.

The low-pressure pump bypass is closed until the ram comes up to the work; then it is opened by means of a handwheel, and the heavy-duty work is completed by the high-pressure pump. The geared screw stem transfer valve alternately operates the hydraulic ram and pull-back.

The press is a recent product of the Charles F. Elmes Engineering Works, Chicago, Ill.

Bar-Straightening Machine

The machine shown is automatic in action and, while designed for straightening and polishing steel shafting, is found equally suitable for straightening iron, brass and



BAR-STRAIGHTENING MACHINE

bronze bars. The operation is continuous after the rolls are set for a certain size of bar. The rate of straightening is about 30 ft. per min.

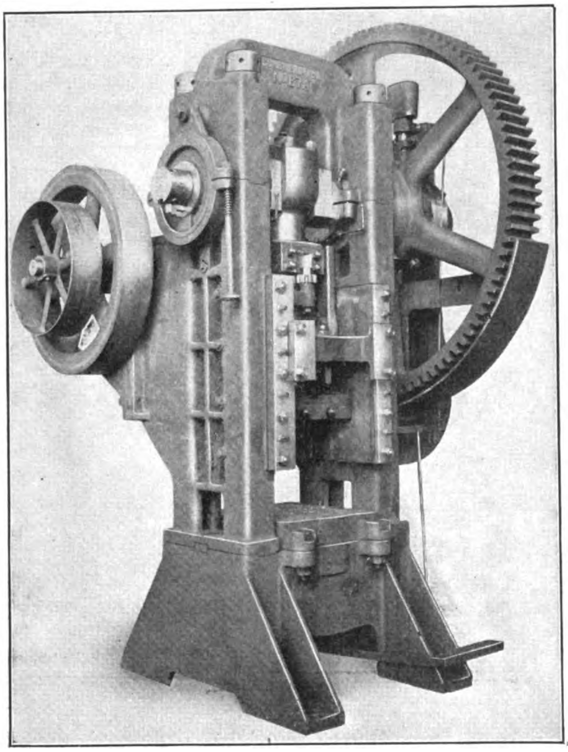
The shaft, or bar, is straightened by passing between two rolls, one of which is ground concave, the other straight. These rolls are set at an angle with each other so that the face of the roll ground straight will be nearly parallel with the concave surface of the other roll. By this means the bar operated on is bent uniformly its entire length, thereby removing all crooks and leaving the bar as straight as is possible to make it by machine operation. These rolls are made of very hard chilled iron, and two sets are furnished: One for rough-straightening—that is, straightening the bars before they are turned—and the other set for restraightening, removing all tool marks, finishing and polishing the shaft after it is turned.

Either set of rolls can be used for polishing to start with, but after using rolls for rough-straightening they should be kept for that purpose only, as they become rough in time and it is not necessary that the rough-straightening rolls have as good a surface as the polishing rolls, which should be kept ground smooth to get good results. The machine is readily set up for the different-sized shafting, and the adjustments are easily made.

The type o' machine shown is made in a variety of sizes and represents a late product of the Medart Patent Pulley Co., St. Louis, Mo. A machine accommodating bars from 1 to 3 in. in diameter and 25 ft. long will occupy a floor space of 30x3 ft.

Heavy Press for General Automobile Work

The press shown was made especially for producing Ford brake drums, but may be used for general automobile or other work of all kinds within its capacity. It is known as No. 67-A and is manufactured by the



PRESS FOR GENERAL AUTOMOBILE WORK

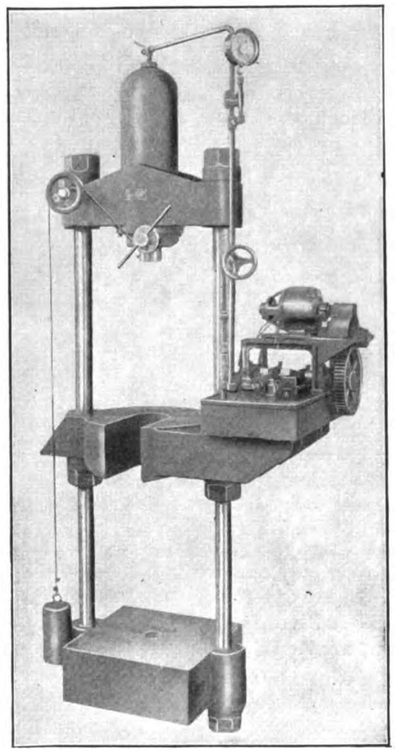
Width between uprights, 28 in.; opening in bed, 12x14 in. (but this can be made to suit customer); die space from top of bolster to face of slide, stroke down, adjustment up, 12 in.; stroke of slide on standard, 4 in.; maximum stroke of slide, 10 in.; adjustment of slide, 4 in.; thickness of bolster, 3½ in.; hole in slide for shank of punch, 3 in. (this is made dovetailed on order); distance between gibs, 18 in.; area of bolster, 30x26 in.; area of face of slide, 18x18 in.; height from floor to center of shaft, 93 in.; flywheel, geared, 48x9 in.; pulleys, 26x7½ in.; ratio of gearing, 8 to 1; floor space, 85x98 in.; weight, about 30,000 lb.

Consolidated Press Co., Hastings, Mich. It is made with either single or double pulleys and is double geared. The frame is grooved and tongued at every joint. Gears and dangerous places are guarded, and nothing has been overlooked to make the machine satisfactory for long and hard shop service.

Hydraulic Forcing Press

The hydraulic press shown is a recent design developed by the Hydraulic Press Manufacturing Co., Mount Gilead, Ohio. It is a double-purpose press, especially intended for two distinct forcing operations, and was constructed primarily for use in forcing locomotive piston rods into the piston heads and also for removing the piston head from the piston rod. However, it can be readily seen that the press is adaptable to a wide range of miscellaneous forcing work coming up in general machine, repair, automobile and railroad shops. The press is also suitable for certain classes of arbor and broaching work, the open slot in the press proper allowing ample space for the arbor forcing operations and providing a place for a broach to pass through.

For forcing the piston head on, the piston head is set on the lower base with the rod passing up through the press base proper, the pressure then being applied from



HYDRAULIC FORCING PRESS

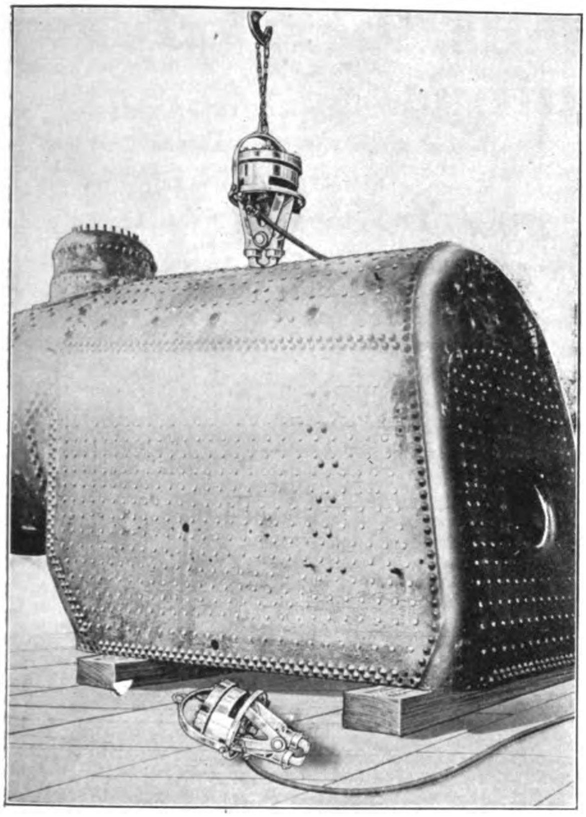
Maximum pressure capacity of upper part, 100 tons; lower part, 50 tons; diameter of ram, 10 in.; length of run, 22 in.; total daylight space, 86 in.

the end of the piston rod, forcing it into the piston head. When the press is used for forcing the piston head off the rod, the piston head with the rod is hung on the press base proper and the pressure applied from the end of the rod, forcing the rod out of the piston head.

This press is self-contained, the pressure being furnished by a direct motor-driven horizontal double-plunger pump with double gear reduction. A T-screw hydraulic operating valve controls the pressure from the pump to the press cylinder.

Pneumatic Stay-Bolt Cutter

The machine shown was primarily intended for cutting locomotive-boiler stay-bolts, but by using an extra set of blades suitable for cutting rivet heads it may be used for all kinds of car, boiler and structural repairs. The machine is composed of an air cylinder and frame combined, the jaws being worked by a lever and toggle movement attached to the 15-in. piston. It is operated at a working pressure of from 90 to 100 lb. of air and will cut off, leaving the proper amount for heading, about 1,200 stay-bolts, ranging from ¾ to 1⅛ in. in diameter, per hour.



While the machine itself differs but little from similar types, the big feature is that it is hung in a sort of universal joint, which is perfectly balanced, so that the operator can with perfect ease swing the big machine to any angle desired. It weighs about 300 lb. and is made by the Baird Pneumatic Tool Co., Topeka, Kan.

Handy Woodworking Vise

It will be observed from the illustrations that the form of vise shown may be used in either a horizontal or a vertical position. The vise automatically locks at any point on the complete circle. The tightening of the jaws simultaneously clamps the vise on its base. The jaws are $2\frac{1}{2}$x$3\frac{1}{2}$ in. and open 5 in. The vise weighs 15 lb.

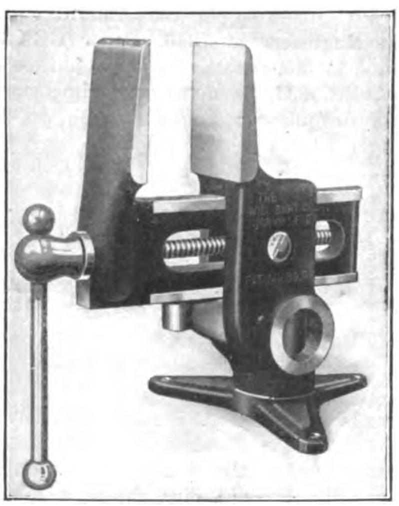


FIG. 1. WOODWORKING VISE

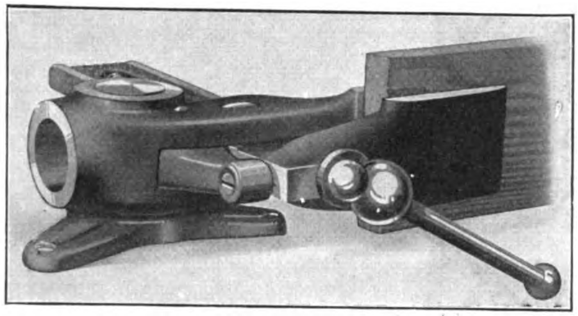

FIG. 2. VISE IN HORIZONTAL POSITION

It is a recent product of the Will-Burt Co., Orrville, Ohio.

Federal Government Will Build a Nitrate Plant

The Army Reorganization Bill as finally enacted authorizes the President to make an investigation to determine the best process "for the production of nitrates and other products for munitions of war and useful in the manufacture of fertilizers and other useful products." He is further authorized to select a water-power site or other site and to construct a plant for the manufacture of such product. The products of the plant are to be used for military and naval purposes to such extent as the President may deem necessary, and any surplus may be sold under such regulations as he may prescribe. The bill does not specify the capacity of the plant, but $20,000,000 is appropriated for its construction and an issue of Panama Canal bonds to raise the money is authorized in case sufficient funds in the treasury are not available. A provision is inserted that the plant must be operated "solely by the Government and not in conjunction with any other industry or enterprise carried on by private capital."

In view of the widely published fact that one of the most needed measures for national defense is the provision of a supply of nitrates that will be available for use at any time the shipment of nitrates from Chile is interrupted, there is no doubt that the Government will proceed promptly with the construction of the plant.

A Rapid Planting Machine

A machine that plants from 10,000 to 15,000 forest-tree seedlings a day is now being used at the Letchworth Park Forest and Arboretum, in Wyoming County, N. Y., according to officials of the Forest Service, who are acting as advisers in the work. Previously the planting has been done by hand at the rate of 1,200 to 1,500 trees each day per man.

The machine was designed to set out cabbage and tomato plants, but works equally well with trees. It is about the size of an ordinary mowing machine and is operated by three men and two horses. One man drives the team while the other two handle the seedlings. The machine makes a furrow in which the trees are set at any desired distance, and an automatic device indicates where they should be dropped.

Straight Pipe Threads for Fixtures and Fittings

Report of A.S.M.E. Committee

SYNOPSIS—This report summarizes the findings of a committee appointed by the American Society of Mechanical Engineers and gives in condensed form the suggested dimensions, formulas and gages for straight pipe threads for fixtures and fittings.

The term "outside diameter" used in this report refers in the case of male threads to the top of the threads or largest diameter, and in the case of female threads to the bottom of the threads or largest diameter. The term "root diameter" similarly refers to the smallest diameter. The "pitch diameter" is of course determined by subtracting from the outside diameter of a theoretical full V-thread the single depth of the thread. Fig. 1 illustrates these various diameters.

Straight Threads Not To Replace Tapers

This report is in no way to be considered as recommending the use of straight pipe threads on pipe in place of taper threads made to the American Briggs Standard. On certain classes of female fittings, however, straight pipe threads are used with entire satisfaction when the engaging male thread is taper and to American Briggs Standard, as a "make up" nonleaking joint is obtained. The use of straight male threads under these conditions is therefore not to be recommended, as an excessive amount of cement is necessary to prevent leaks. Often, however, in fixture work such a joint is not necessary and is in many cases undesirable for purposes of finish, and in such cases straight male threads may be used to advantage. It will be manifest upon inspection of the figures given in Tables 1 and 3 that a female threaded fitting will not screw down to the end of the thread, but will "make up" at a proper point, which is normally to be desired; further, from inspection of Tables 1 and 5, that the ⅛-in. socket caps will screw down to end of the thread without "make up," which in this particular case is desired. Also, by comparison of Tables 2 and 3 together and Tables 2 and 5 together, it will be noted that the female fitting will not "make up" at any point, but will show a slight looseness at all points, making the use of a considerable amount of cement necessary if a nonleaking joint is desired.

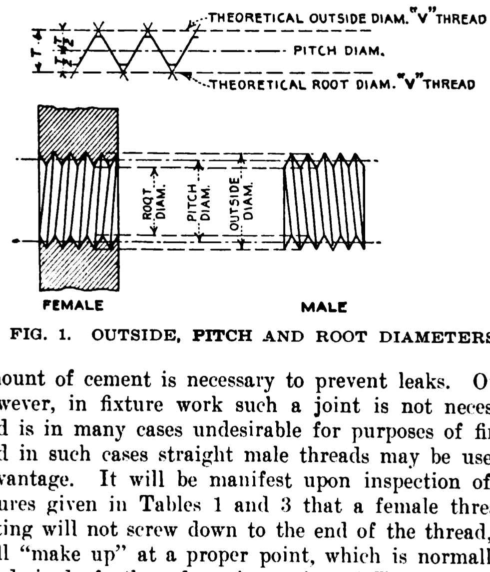

FIG. 1. OUTSIDE, PITCH AND ROOT DIAMETERS

The notch on the American Briggs Standard which is located by the thickness of the American Briggs Ring is well recognized as locating the proper point on the standard for the measurement of the pitch diameter of straight pipe size threads. The thickness of this ring was recommended for each size of pipe by the Committee on Standardization of Pipe Thread Gages appointed by the American Society of Mechanical Engineers, working in conjunction with the Committee of Manufacturers on Standardization of Valves and Fittings. Further, this latter committee adopted the sizes at the notch as correct for straight pipe threads. The angle, form and pitch of the thread are of course the same as on the American Briggs Standard.

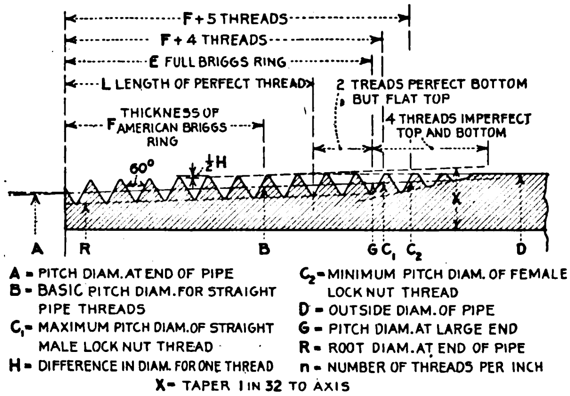

FIG. 2. BASIC STRAIGHT PIPE SIZES

Formulas for Basic Pitch Diameter

The report of the Committee on Standard Pipe and Pipe Threads presented to the American Society of Mechanical Engineers in 1886, Paper CCXXVI, and supplemented by the report of the Committee on Gages previously mentioned, gives standard dimensions of pipe and certain formulas shown in Fig. 2. In this figure

$$L = \frac{0.8D + 4.8}{n} \qquad E = L + 2\left(\frac{1}{n}\right)$$

$$R = D - \frac{0.05D + 1.9}{n} \qquad A = R + \frac{0.8}{n}$$

$$B = A + \frac{F}{16} \qquad G = A + \frac{E}{16}$$

$$H = \frac{1}{16n}$$

The sizes shown in Fig. 2 and previously described were adopted by the Committee of Manufacturers on Standardization of Fittings and Valves on Sept. 17, 1913, except the straight pipe thread and the locknut sizes, which were later adopted by the same committee

on Mar. 16, 1915. The figures for the various pipe sizes as published by that committee are given in Table 1, with the addition of columns headed *D, G* and *H.*

Tolerances Suggested

The maximum tolerances taken on the pitch diameters by the Committee of Manufacturers on Standardization of Fittings and Valves are one thread above and one thread below *basic* sizes, or a total of twice *H*, Table 1.

While your committee recommends the same *basic* sizes as the foregoing committee and concurs with it in its recommendation for tolerances on pipe fittings with straight threads, yet for the special fittings hereafter mentioned it is necessary to use different tolerances. The straight pipe threads recommended by the Committee of Manufacturers are almost universally used on female fittings only, and the tolerance that is taken above and below *basic* size is therefore eminently a proper one. This is not the case, however, when both male and female fittings have straight threads, and a careful survey of the product in consultation with manufacturers and users developed that the following maximum tolerances be allowed on pitch diameters: 0.004 in. on 1/8-in. pipe size; 0.005 in. on 1/4-in. and 3/8-in. pipe size; 0.006 in. on 1/2-in. and 3/4-in. pipe size; 0.007 in. on 1-in. pipe size.

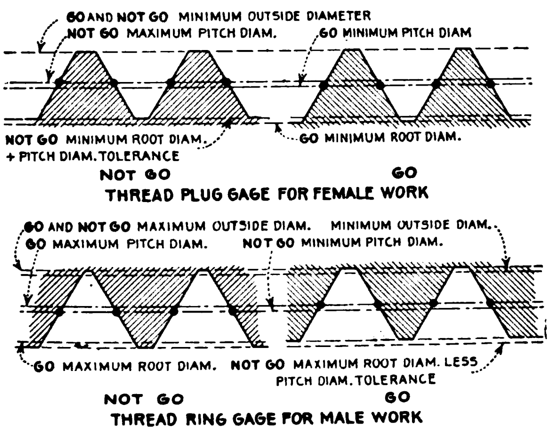

FIG. 3. "GO" AND "NOT GO" GAGES

These tolerances should be taken over *basic* sizes for female fittings, and under *basic* sizes for male fittings. When female fittings with these tolerances are used with male fittings made taper to American Briggs Standard, a proper "make up" joint will result. One inch is the largest pipe size in use on this work.

In order to allow sufficient wear for taps and dies and as it is further recognized that a thread three-quarters full depth is not too flat for commercial practice, it is recommended that the minimum outside diameter of female threads and the maximum root diameter of male threads be made United States Standard and that the maximum root diameter of female threads and the minimum outside diameter of male threads be such that three-quarters of the depth of a full V-thread results. The maximum outside diameter of female threads and the minimum root diameter of male threads is purposely not specified so that manufacturers may, if so desired, start their taps and dies full V-thread and allow them to wear to the specified limits already given. All calculations for root and outside diameters should be based on the pitch diameters.

The length of thread should not be less than the full Briggs ring.

Threaded gages should be made primarily to check the pitch diameters. The maximum allowable flatness of thread should be checked by plain gages. Gages for female fittings made to maximum sizes should not enter, and made to minimum should enter, the fittings. Gages for male fittings made to maximum sizes should be entered by, and made to minimum sizes should not be entered by, the fittings. This will insure the fittings being made with less variation than the allowed tolerances.

Reference Gage Dimensions for Male and Female Fittings

It will be noted above that a flatness of three-quarters of a full V-thread is recommended in extreme cases. This is to cover commercial practice in tapping and threading sheet-metal shells. Working gages for fittings turned from rod may, however, ignore this allowance. Further, in order that the pitch diameter may always be properly gaged, clearance should be allowed on the outside thread diameters of the gages; Fig. 3 and the dimensions given hereafter in connection with Tables 2, 3, 4 and 5 cover these points.

The tables on the following page give the results of the findings of the committee in a condensed and readily usable form.

* For sizes above 10 in. the preceding formulas should also be used.

FOR MALE FITTINGS

Reference Gages

"Not Go" Threaded Ring

Outside diameter = Maximum
Pitch diameter = Minimum
Root = Maximum less pitch-diameter tolerance

"Go" Threaded Ring

Outside diameter = Maximum
Pitch diameter = Maximum
Root = Maximum

"Not Go" Plain Ring

Diameter = Minimum outside diameter

"Go" Plain Ring

Diameter = Maximum outside diameter

Working Gages

For sheet-metal work same as reference gages above.
For turned work threaded rings and "Go" plain ring same as reference gages above.

"Not Go" Plain Ring

Diameter = Maximum outside diameter less pitch-diameter tolerance

FOR FEMALE FITTINGS

Reference Gages

"Not Go" Threaded Plug

Outside diameter = Minimum
Pitch diameter = Maximum
Root diameter = Minimum plus pitch-diameter tolerance

"Go" Threaded Plug

Outside diameter = Minimum
Pitch diameter = Minimum
Root diameter = Minimum

"Not Go" Plain Plug

Diameter = Maximum root diameter

"Go" Plain Plug

Diameter = Minimum root diameter

Working Gages

For sheet-metal work same as reference gages above.
For turned work threaded plugs and "Go" plain plug same as reference gages above.

"Not Go" Plain Plug

Diameter = Minimum root diameter plus pitch-diameter tolerance

The tolerance on pitch diameter will be known as T. The formulas are:

MALE FITTINGS

$$\text{Maximum pitch diameter} = B$$
$$\text{Maximum root diameter} = B - \frac{0.64952}{n}$$
$$\text{Maximum outside diameter} = B + \frac{0.64952}{n}$$
$$\text{Minimum pitch diameter} = B - T$$
$$\text{Minimum outside diameter} = B - T + \tfrac{1}{2}\left(\frac{0.86603}{n}\right)$$

FEMALE FITTINGS

$$\text{Maximum pitch diameter} = B + T$$
$$\text{Maximum root diameter} = B + T - \tfrac{1}{2}\left(\frac{0.86603}{n}\right)$$
$$\text{Minimum pitch diameter} = B$$
$$\text{Minimum root diameter} = B - \frac{0.64952}{n}$$
$$\text{Minimum outside diameter} = B + \frac{0.64952}{n}$$

Tables 2 and 3 are given for convenience, being derived from the foregoing formulas.

TABLE 2. SPECIAL STRAIGHT FIXTURE PIPE THREADS; MALE THREADS

Dimensions in Inches

Pipe Size	Threads per In.	Maximum Diam. Outside	Maximum Diam. Pitch Basic	Maximum Diam. Root	Minimum Diam. Outside	Minimum Diam. Pitch	Tolerance Pitch Diam.	Minimum Length of Thread
1/8	27	0.3989	0.3748	0.3507	0.3868	0.3708	0.004	0.2638
1/4	18	0.5260	0.4899	0.4538	0.5089	0.4849	0.005	0.4018

1/2	14	0.8248	0.7784	0.7320	0.8033	0.7724	0.006	0.5337
3/4	14	1.0353	0.9889	0.9425	1.0138	0.9829	0.006	0.5457
1	11½	1.2951	1.2386	1.1821	1.2692	1.2316	0.007	0.6828

TABLE 3. SPECIAL STRAIGHT FIXTURE PIPE THREADS; FEMALE THREADS

Dimensions in Inches

Pipe Size	Threads per In.	Maximum Diam. Pitch	Maximum Diam. Root	Outside	Minimum Diam. Pitch Basic	Root	Tolerance Pitch Diam.	Minimum Length of Thread
1/8	27	0.3788	0.3628	0.3989	0.3748	0.3507	0.004	0.2638
1/4	18	0.4949	0.4709	0.5260	0.4899	0.4538	0.005	0.4018
3/8	18	0.6320	0.6080	0.6631	0.6270	0.5909	0.005	0.4078
1/2	14	0.7844	0.7535	0.8248	0.7784	0.7320	0.006	0.5337
3/4	14	0.9949	0.9640	1.0353	1.9889	0.9425	0.006	0.5457
1	11½	1.2456	1.2080	1.2951	1.2386	1.1821	0.007	0.6828

While the sizes given in Tables 2 and 3 should be satisfactory on gas burners, fixture nipples, insulating joints, hickeys and the general run of similar fittings for all female threads and for male threads when straight threads are necessary, they are not safely usable on electric socket caps, as the fit with the nipple or coupling should be sufficiently loose to permit the cap to be easily screwed down to the shoulder without strain.

ELECTRIC SOCKET CAPS

Pipe couplings into which male electric socket caps are screwed are commercially made with a tolerance of one thread each side of the notch on the American Briggs Standard as adopted by the Committee of Manufacturers on Standardization of Fittings and Valves. Therefore, it is desirable that the maximum be less than basic size by 0.001 in. more than one thread. Referring to Fig. 2,

$$\textit{Maximum pitch diameter} = B - (H + 0.001)$$

The tolerances as well as the relative root and outside diameters are given in Table 4; in this the minimum lengths of thread recommended are also shown.

TABLE 4. SPECIAL STRAIGHT ELECTRIC FIXTURE THREADS; MALE ELECTRIC CAPS, ETC.

Dimensions in Inches

Pipe Size	Threads per In.	Maximum Diam. Outside	Maximum Diam. Pitch	Root	Minimum Diam. Outside	Minimum Diam. Pitch	Tolerance Pitch Diam.	Minimum Length of Thread
1/8	27	0.3956	0.3715	0.3474	0.3835	0.3675	0.004	0.250
1/4	18	0.5215	0.4854	0.4493	0.5044	0.4804	0.005	0.281
3/8	18	0.6586	0.6225	0.5864	0.6415	0.6175	0.005	0.281
1/2	14	0.8193	0.7729	0.7265	0.7978	0.7669	0.006	0.375
3/4	14	1.0298	0.9834	0.9370	1.0083	0.9774	0.006	0.375
1	11½	1.2887	1.2322	1.1757	1.2628	1.2252	0.007	0.500

The ⅛-in. size female is most largely used; and owing to the oversize fixture nipples now in use an arbitrary minimum pitch diameter of 0.3790 in. is recommended. This size will not be too loose on standard nipples. For sizes above ⅛ in. a minimum pitch diameter one thread larger than basic is taken:

$$\textit{Minimum pitch diameter} = B + H$$

Tolerances on all sizes should be the same as previously established, the root and outside diameters being proportional. Table 5 is derived for convenience, and in it the minimum length of thread recommended is shown.

The committee recommends the use of straight pipe threads and locknut threads as adopted by the Committee of Manufacturers on Standardization of Fittings and Valves, as described, and also the use of the special straight threads. It further recommends that there be deposited with the Bureau of Standards, Washington, D. C., master gages, the expense of such gages to be borne by the manufacturers.

TABLE 5. SPECIAL STRAIGHT ELECTRIC FIXTURE THREADS, FEMALE ELECTRIC CAPS, ETC.

Dimensions in Inches

Pipe Size	Threads per In.	Maximum Diam. Pitch	Maximum Diam. Root	Outside	Minimum Diam. Pitch	Root	Tolerance Pitch Diam.	Minimum Length of Thread
1/8	27	0.3830	0.3670	0.4031	0.3790	0.3549	0.004	0.2638
1/4	18	0.4984	0.4744	0.5295	0.4934	0.4573	0.005	0.4018
3/8	18	0.6355	0.6115	0.6666	0.6305	0.5944	0.005	0.4078
1/2	14	0.7889	0.7580	0.8293	0.7829	0.7365	0.006	0.437
3/4	14	0.9994	0.9685	1.0398	0.9934	0.9470	0.006	0.437
1	11½	1.2510	1.2134	1.3005	1.2440	1.1875	0.007	0.500

The straight pipe threads recommended by the Committee of Manufacturers on Standardization of Fittings and Valves are known by that name. The committee, therefore, recommends the use of this name for these standards only, and that the special standards previously described be known as special straight fixture pipe threads and special straight electric fixture threads respectively.

Edward S. Sanderson, Chairman, Harry E. Harris, William J. Baldwin, Stanley G. Flagg, Jr., Charles R. Hare, A. H. Moore, W. R. Webster and George B. Thomas, Secretary.

NEW PUBLICATIONS

LATHE DESIGN, CONSTRUCTION AND OPERATION—By Oscar E. Perrigo. Revised edition; four hundred and sixty 6x9 in. pages; 341 illustrations; indexed; cloth bound. The Norman W. Henley Publishing Co., New York City. Price, $2.50.

This is a new edition of a work originally brought out in 1907. In its present form the book has been revised and enlarged. A chapter has been added, detailing all kinds of lathe work, treating of lathe installation and management, milling, drilling and grinding attachments and their use, methods of turning tapers, turning spherical surfaces, making oil grooves and many other processes pertaining to practical lathe work. This matter has been prepared in such a form as to be readily followed by any apprentice, student or amateur machinist.

THE "MECHANICAL WORLD" POCKET DIARY AND YEAR BOOK FOR 1916. Two hundred and sixty-three 4x6-in. pages; illustrated; indexed; cloth bound. Price, 25 cents; 30 cents postpaid. The Norman, Remington Co., Baltimore, Md.

This is the twenty-sixth year of the issue of this pocket book, which is in keeping with those that have been published before.

A number of new features have been introduced, among them being the following: The section on steam boilers has been largely rewritten. There is a separate and enlarged section on the Diesel engine, embodying many concisely arranged data. Notes are given dealing with brazing and soldering, also new tables on these subjects, and on Lancashire and Cornish boilers, steel plates, friction clutches and one table for circle spacing.

The book is in a convenient form and contains much valuable information for the designer, the draftsman and the machinist.

PERSONALS

W. H. Neumeister, for sometime past a member of the machinist ranks of the Sioux City Welding and Machine Works, Sioux City, Iowa, has been promoted to the superintendency.

A. F. Orcutt, for some time past a member of the executive force of Deere & Co., Moline, Ill., has been appointed general manager of the Rivett Lathe and Grinder Co., Boston, Mass.

C. S. Maurer, formerly superintendent of the Independent Motor Co., Port Huron, Mich., has become agent and distributor of the Republic Motor Co., Alma, Mich. Mr. Maurer's headquarters will be in Findlay, Ohio.

Jack C. Carlton, formerly with the Lodge & Shipley Machine Tool Co., has organized and become president of the Carlton Machine Tool Co., Cincinnati, Ohio, successors to the William E. Gang Co., of the same city.

Otto Faber, until recently sugar engineer with the Palmarito de Canto, Oriente, Cuba, has become associated with the George L. Squier Co., Buffalo, N. Y., for which he will be in charge of the design and erection of sugar machinery.

J. E. Greensmith, formerly general manager of the Mason Machine Works, Taunton, Mass., and more recently assistant general manager of the New England Westinghouse Co., has resigned the latter position to become president of the Boston Scale and Machine Co., Boston, Mass.

OBITUARY

Mortimer H. Wright, one of the founders and superintendent of the Pennsylvania Shafting Co., Spring City, Penn., died in that city on May 28, after a brief illness. Mr. Wright was 49 years old.

James B. Wise, of Watertown, N. Y., who had attracted considerable attention since the outbreak of the war by his rapid development of a large cartridge and cartridge-machinery manufacturing business, died at Atlantic City, N. J., on June 7. Mr. Wise's regular business was the manufacture of plumbing supplies. He was 58 years old and a native of Stamford, Conn.

John Barnes, president and for many years the guiding mechanical spirit of the W. F. & John Barnes Co., Rockford, Ill., died at his home in that city on May 29 after a long illness induced by old age. Mr. Barnes was born in Mt. Morris, N. Y., in 1833 and when a young man migrated to Rockford, Ill. In 1872 he formed a partnership with his brother W. F. Barnes for the manufacture of foot-power machinery which partnership culminated in the formation of the present company which has become so well known in the field. In addition to his business capacity, to which much of the growth of his company was attributed, Mr. Barnes had a fertile mechanical imagination and was responsible for many of the designs and devices developed by his company during its existence from the pioneer days. While retaining the presidency of the organization Mr. Barnes withdrew from active management in 1908, since which time his sons Aubrey T. and John S. have been in charge. Mr. Barnes was for many years a conspicuous figure in the civic affairs of Rockford and at the time of his death was chairman of the Board of Trustees of Rockford College.

BUSINESS ITEM

To meet the requirements of its growing business the Norma Company of America announces plans for the erection of a four-story reinforced-concrete, 70x350-ft. building on a 10-acre site in Elmhurst, Long Island, which is on the outskirts of Long Island City.

TRADE CATALOGS

Rex Tool Post. Rex Mfg. Co., Hyde Park, Boston, Mass. Circular. Illustrated.

Screw Plates. Russell Mfg. Co., Greenfield, Mass. Catalog No. 2. Pp. 48. 5x7½ in.

Mr. R. Boehnke, Jr., 7 Tooronga Road, Upper Hawthorn, Victoria, Australia, would like to receive catalogs of machine tools used in the manufacture of automobile parts, including gear-cutting machines, drillers, slotters, grinders,

FORTHCOMING MEETINGS

Master Car Builders' Association. Annual meeting, June 14-17, Atlantic City, N. J. Joseph W. Taylor, secretary, Karpen Building, Chicago, Ill.

American Railway Master Mechanics' Association. Annual meeting, June 17-21, Atlantic City, N. J. Joseph W. Taylor, secretary, Karpen Building, Chicago, Ill.

American Society for Testing Materials. Annual meeting June 27 to July 1, 1916, Hotel Traymore, Atlantic City, N. J. Edgar Warburg, secretary, University of Pennsylvania, Philadelphia, Penn.

American Foundrymen's Association and American Institute of Metals. Annual meeting, September 11-16, Cleveland, Ohio, A. O. Backert, secretary, American Foundrymen's Association, Cleveland, Ohio.

American Society of Mechanical Engineers. Monthly meeting first Tuesday. Calvin W. Rice, secretary, 29 West Thirty-ninth St., New York City.

Boston Branch National Metal Trades Association. Monthly meeting on first Wednesday of each month, Young's Hotel. W. W. Poole, secretary, 40 Central St., Boston, Mass.

Providence Association of Mechanical Engineers. Monthly meeting fourth Wednesday each month. J. A. Brooks, secretary, Brown University, Providence, R. I.

New England Foundrymen's Association. Regular meeting second Wednesday of each month. Exchange Club, Boston, Mass. Fred F. Stockwell, 205 Broadway, Cambridgeport, Mass.

Engineers' Society of Western Pennsylvania. Monthly meeting third Tuesday; section meeting, first Tuesday. Elmer K. Hiles, secretary, Oliver Building, Pittsburgh, Penn.

Rochester Society of Technical Draftsmen. Monthly meeting, last Thursday. O. L. Angevine, Jr., secretary, 857 Genesee St., Rochester, N. Y.

Superintendents' and Foremen's Club of Cleveland. Monthly meeting third Saturday. Philip Frankel, secretary, 310 New England Building, Cleveland, Ohio.

Western Society of Engineers, Chicago, Ill. Regular meeting first Wednesday evening of each month, excepting July and August. J. H. Warder, secretary, 1785 Monadnock Block, Chicago, Ill.

Philadelphia Foundrymen's Association. Meetings first Wednesday of each month. Manufacturers' Club, Philadelphia, Penn. Howard Evans, secretary, Pier 45 North, Philadelphia, Penn.

Technical League of America. Regular meeting second Friday of each month. Oscar S. Teale, secretary, 35 Broadway, New York, N. Y.

Prices--Materials and Supplies

IRON AND STEEL

Pig Iron—Quotations were current as follows at the points and dates indicated:

	June 9, 1916	One Month Ago	One Year Ago
No. 2 Southern Foundry, Birmingham	$14.75	$15.00	$9.50
No. 2 X Northern Foundry, New York	20.25	20.75	14.00
No. 2 Northern Foundry, Chicago	19.00	19.00	13.00
Bessemer, Pittsburgh	21.95	21.95	14.55
Basic Pittsburgh	18.95	18.95	13.45
No. 2 X, Philadelphia	20.25	20.50	....
No. 2 Valley	18.00	18.50	....

No. 10 blue annealed	4.25	4.25	...	3.55	3.50
No. 28 galvanized	5.65	5.65	5.50	5.50	5.50
No. 26 galvanized	5.35	5.35	5.20	5.20	5.20
No. 24 galvanized	5.20	5.20	5.05	5.05	5.05

Standard Pipe—The following table shows the comparison in discounts, together with the net prices in cents per foot for carload lots f.o.b. mill:

	Black June 9, 1916	Black One Yr. Ago	Galvanized June 9, 1916	Galvanized One Yr. Ago
¾ to 2 in. steel butt welded	70%	81%	50½%	72½%
2½ to 6 in. steel lap welded	68%	80%	48½%	72½%
Diameter, In.				
¾	3.45	2.19	5.69	3.16
1	5.10	3.23	8.42	4.68
1¼	6.90	4.37	11.39	6.33
1½	8.25	5.23	13.61	10.18
2	11.10	7.03	18.32	10.18
2½	18.72	11.70	30.13	16.09
3	24.48	15.30	39.40	21.04
4	34.88	21.80	56.14	29.98
5	47.36	29.60	76.22	40.70
6	61.44	38.40	98.88	52.80

From New York stock the following discounts hold:

	Black	Galvanized
3½ to 6 in. steel lap welded	61%	36%
¾ to 3 in. steel butt welded	64%	42%

Malleable fittings, Class B and C, from New York stock sell at 30 and 5% from list price. Cast iron, standard sizes, 55%.

Bar Iron—Prices are as follows in cents per pound at the places named:

	June 2, 1916	One Month Ago
Pittsburgh, mill	2.60	2.50
Warehouse, New York	3.25	3.25
Warehouse, Cleveland	3.25	3.25
Warehouse, Chicago	3.10	3.10

Cold Drawn Steel Shafting—From warehouse to consumers requiring fair-size lots, the following quotations hold:

	June 9, 1916	One Month Ago
New York	List price plus 20%	List price plus 20%
Cleveland	List price plus 20%	List price plus 20%
Chicago	List price plus 10%	List price plus 10%

Swedish (Norway) Iron—This material per 100 lb. sells as follows f.o.b. places named:

New York Today	New York One Year Ago	Cleveland	Chicago
$6.00	$3.75@4.00	$6.30	$5.25

In coils an advance of 50c. is usually charged.

Drill Rod—Discounts from list price in New York are as follows: Standard, 65%; extra, 60%; special, 55%.

High Speed Tool Steel containing from 10 to 18% tungsten sells as follows per pound in New York:

Billets ....$2.40 Bars $3.25

METALS

Miscellaneous Metals—The present quotations in cents per pound, with a comparison of practically a month and year ago, are as follows:

	New York June 9, 1916	New York One Month Ago	New York One Year Ago
Copper, electrolytic (carload lots)	29.00	30.50	19.00
Tin	45.00	51.50	38.00
Lead	7.00	7.50	5.00
Spelter	13.75	18.00	27.00
ST. LOUIS			
Lead	7.00	7.37½	...
Spelter	13.62½	17.87½	...

At the places named, the following prices in cents per pound prevail:

	New York June 9, 1916	New York One Month Ago	New York One Year Ago	Cleveland	Chicago
Copper sheets, base	37.50	36.50	24.00	38.50	37.50
Copper wire (carload lots)	37.50	36.50	21.50	33.00	38.00
Brass, rods, base	44.50	44.00	20.50	42.00	38.00
Brass pipe, base	46.50	44.50	23.50	45.00	46.00
Brass sheets	44.50	43.00	20.50	42.00	38.00
Solder ½ and ½ (case lots)	28.00	31.62½	28.00	32.50	28@30

Old Metals—The following are the dealers' purchasing prices in cents per pound:

	New York June 9, 1916	New York One Month Ago	Cleveland June 9, 1916	Cleveland One Month Ago
Copper, heavy and crucible	23.50	25.00	23.50	25.00
Copper, heavy and wire	23.00	24.50	23.00	24.00
Copper, lhite and bottoms	19.50	22.00	20.00	24.00
Lead, heavy	5.50	6.00	6.00	7.00
Lead, tea	5.00	5.50	5.00	6.00
Brass, heavy	13.50	14.50	13.50	20.00

The Pennsylvania Lines West of Pittsburgh plans to enlarge its repair shops at Richmond, Ind. Estimated cost, $500,000. Thomas Rodd, Pittsburgh, Penn., Ch. Engr.

The H. B. Sherman Manufacturing Co., manufacturer of brass goods, Barney and Kalamazoo St., Battle Creek, Mich., is in the market for a second-hand, high-grade, good condition, short use Allis-Chalmers or equivalent 250-hp. engine, horizontal boilers 125-hp. each or an engine of similar capacity direct connected with generator 200-kw., alternating-current, 3-phase, 220-volt current.

Plans have been prepared for several additions to the plant of the Detroit Heating and Lighting Co., Detroit, Mich., manufacturer of sheet metal specialties for automobiles.

Dodge Bros., Detroit, Mich., manufacturer of automobiles, plans to construct an addition to its plant.

The England Manufacturing Co., manufacturer of automobile parts, is constructing a new factory at Leavitt and Campbell Ave., Detroit, Mich.

An addition will be constructed to the plant of the Fisher Body Co., Detroit, Mich., manufacturer of auto and carriage bodies. Estimated cost, $10,000.

The Studebaker Corporation, Detroit, Mich., manufacturer of automobiles, contemplates another addition to its plant.

The O. E. Aëroplane Co., Fenton, Mich., recently incorporated with $25,000 capital stock, plans to construct a factory at Fenton for the manufacture of aëroplanes.

Plans have been prepared for the construction of a factory for the manufacture of heating furnaces for the Home Furnace Co., Holland, Mich. New foundry machinery and sheet metal tools will be required.

An addition is being built to the plant of the Michigan Crank Shaft Co., Lansing, Mich., manufacturer of machinery.

The Globe Manufacturing Co., Northville, Mich., manufacturer of automobile trucks, will construct an addition to its plant.

Bids are being received for the construction of a 2-story garage at Pontiac, Mich., for Howard Fawcett. Estimated cost, $20,000. Noted Apr. 27.

According to press reports the W. O. Lee Co., Port Huron, Mich., manufacturer of brass goods and injectors, plans to increase the capacity of its plant.

The Alemite Metal Co., manufacturer of metal specialties, has moved its plant to 341-51 West Chicago Ave., Chicago, Ill., and plans to install new machinery.

The contract has been awarded for the construction of a machine shop at Chicago, Ill., for the Chicago Junction Railway Co.

The contract has been awarded for the construction of a new factory for the Englander Spring Bed Co., 39th St. and Lowe Ave., Chicago, Ill.

The contract has been awarded for the construction of a 1-story garage at 1227-29 Cleybourn Ave., Chicago, Ill., for A. F. Mayer & Bros. Estimated cost, $12,000.

The Santa Fe System is in the market for a number of machine tools. C. F. W. Felt, Chicago, Ill., Ch. Engr.

Plans are being prepared for an addition to the factory of the Templeton, Kenly & Co., Ltd., 1020 South Central Ave., Chicago, Ill., manufacturer of railway supplies.

The Shankin Manufacturing Co., Springfield, Ill., manufacturer of brass, is building a factory at 11th St. and Stanford Ave. Estimated cost, $10,000.

An addition is being built to the plant of the Lyon Metallic Manufacturing Co., Yorkville, Ill., manufacturer of metal lockers. Estimated cost, $15,000.

R. A. Boehme, Alma, Wis., and B. L. Bruggeman, Minneapolis, Minn., will establish a machine shop and automobile business in the Boehme Bldg., Alma, Wis.

Plans are being prepared for the construction of a 1-story garage at Black River Falls, Wis., for August Berg, Melrose, Wis. Estimated cost, $10,000.

J. R. McDonald, Main St., Black River Falls, Wis., will construct a garage at Black River Falls. Estimated cost, $10,000.

The Hudson Sharp Machine Co. and the Sectional Roll Manufacturing Co., Green Bay, Wis., have merged into company with a capital of $60,000 and plan to equip a plant with lathes, shapers and other iron working machinery.

Paul H. W. Pagel, Kaukauna, Wis., will construct a garage and service station at Kaukauna.

The Laursen Automatic Pump Co., Menomonee, Wis., manufacturer of mining and irrigation pumps, plans to establish a branch plant at Green Bay, Wis. George D. Nau, Green Bay, is interested.

The contract has been awarded for the construction of a 1-story garage for Ira Ludwig, 2316 Aurer Ave., Milwaukee, Wis. Estimated cost, $10,000. Noted Apr. 27.

Bids will be received until July 1 by Fred Maettig, Arch., 2906 North Ave., Milwaukee, Wis., for the construction of a garage and factory. Estimated cost, $25,000.

Plans are being prepared by R. E. Oberst, Arch., 353 National Ave., Milwaukee, Wis., for the construction of a garage and machine shop at Lapham St. and 2nd Ave.

Demars Bros., Washburn, Wis., will construct an addition to their service garage to be used for machine shop purposes.

Press reports state that the Jersild Fire Escape Co., Neenah, Wis., plans to establish its permanent works at Waupaca, Wis. J. N. Jersild is Pres. and Gen. Mgr.

WEST OF THE MISSISSIPPI

The Globe Manufacturing Co., manufacturer of washing machines, plans to rebuild its factory at Perry, Iowa, which was recently destroyed by fire. Estimated cost, $30,000.

The contract has been awarded for the construction of a garage at Sheffield, Iowa, for J. P. McCammant. Estimated cost, $13,241.

Preliminary plans are being prepared for the construction of a 2-story garage for H. A. Wetmore, 515 6th St., Sioux City, Iowa. Estimated cost, $35,000.

Plans are being prepared for the construction of a factory at North St. Paul, Minn., for the Minnesota Manufacturers Association, manufacturer of elevator and gravity carriers.

The Willys-Overland Automobile Co. has purchased a site on University Ave., St. Paul, Minn., and plans to construct an addition to its plant.

The Drake-Williams-Mount Co., manufacturer of boiler, tank and sheet iron, has been granted a permit for the construction of a factory at 23rd and Hickory St., Omaha, Neb. Estimated cost, $5,900.

The contract has been awarded for the construction of a 2-story garage at 9th St. and Broadway, Hannibal, Mo., for Thomas L. Anderson. Estimated cost, $12,000. Noted Mar. 9.

The contract has been awarded for the construction of a garage at St. Louis, Mo., for the Velie Motor Car Co., 3021 Locust St., St. Louis.

Bids have been received for the construction of a garage at Abilene, Tex., for J. M. Radford.

Thomas S. Causey and associates plan to construct a plant at Dallas, Tex., for the manufacture of a newly patented thermal generator.

The Moore-Schillinger Co., Inc., plans to construct a plant at El Paso, Tex., for the manufacture of ornamental iron and wire work.

The Farmers Coöperative Gin Co. plans to construct a cotton gin at Seguin, Tex.

The contract has been awarded for the construction of a garage at Sherman, Tex., for Lee Simmons. Estimated cost, $10,000.

WESTERN STATES

J. J. Callahan plans to construct a garage at Yakima and Naches Ave., North Yakima, Wash. Estimated cost, $22,000.

Plans are being prepared by H. Ryan, Arch., Northern Bank Bldg., Seattle, Wash., for the construction of a 120x120-ft. garage and machine shop at Seattle for the Winton Motor Car Co. Estimated cost, $65,000.

Plans are being prepared for the construction of a garage and machine shop at Big Pine, Calif., for J. H. Kispert, Los Angeles.

CANADA

The Dominion Bridge Co., Ltd., is constructing an addition to its copper mill and a new forge shop at Lachine, Que. Estimated cost, $17,000.

E. C. Dennert, care of Hill Bros., Essex, Ont., will construct a factory at Essex for the manufacture of auto tractors, machinery, etc.

F. Callendar plans to construct a foundry at Guelph, Ont. Estimated cost, $7,000.

Work will soon be started on the construction of a plant at Weston, Ont., for the Canada Cycle and Motor Co. Estimated cost, $100,000.

GENERAL MANUFACTURING

NEW ENGLAND STATES

The Knox Woolen Co. is constructing an addition to its plant at Camden, Maine.

The contract has been awarded for the construction of a 2-story shoe factory at Manchester, N. H., for the F. M. Hoyt Shoe Co., Sulver St. Estimated cost, $30,000.

The Quincy Market Cold Storage and Warehouse Co. plans to construct a 9-story cold-storage plant at Boston, Mass.

The contract has been awarded for the construction of an addition to the box factory of Atwood & McManuson, Vale St., Chelsea, Mass.

The International Worsted Mills has awarded the contract for the construction of a 1-story weave shed at Methuen, Mass. Estimated cost, $12,000.

The contract has been awarded for the construction of a 2-story, 70x120-ft. mill on Dexter St., Providence, R. I., for the Simmons Braid Co. Noted June 1.

MIDDLE ATLANTIC STATES

Plans are being prepared by Pierce & Bickford, Arch., 118 Lake St., Elmira, N. Y., for the construction of a 1-story dye plant. Estimated cost, $20,000.

The Wyckoff Knitting Co., Perry, N. Y., plans to construct a large addition to its plant.

The Rochester Folding Box Co., Rochester, N. Y., is in the market for lithographing presses, box machinery, etc., for the new factory which it is building on Elizabeth St. between Lake Ave. and Genesee River, Rochester. Estimated cost, $175,000. H. C. Stevenson, Secy. and Treas. Noted June 1.

The United Paper Board Co., Thomson, N. Y., has had plans prepared for alterations to its factory. Estimated cost, $5,000.

The Vacuum Oil Co., Bayonne, N. J., has had plans prepared for several additions to its plant. L. V. Van Leuven, Engr.

The American Lead Pencil Co., Hoboken, N. J., has acquired property on 8th St. for extensions to its plant.

The Celluloid Co., 290 Ferry St., Newark, N. J, has awarded the contract for the construction of a 2-story manufacturing building. Estimated cost, $20,000. M. Martin, Supt., in charge.

The Hoboken Ribbon Co., 11th St., Hoboken, N. J., has awarded the contract for the construction of a 4-story factory at North Bergen, N. J. Estimated cost, $35,000. William Strittmater, Hoboken, Supt., in charge.

The Atlantic Silk Co., Paterson, N. J., plans to install new equipment in its plant.

B. E. Davis, 366 Godwin St., Paterson, N. J., will construct a 3-story addition to its silk mill. Estimated cost, $12,000.

The Pearl Silk Co., Paterson, N. J., plans to install new equipment in its plant.

The Perth Amboy Chemical Works, Perth Amboy, N. J., will construct a 2-story brick and steel addition to its plant.

Stork Bros., Adamstown, Penn., have leased and are remodeling building at Akron, Penn., for hosiery mill.

Plans are being prepared for the construction of a 1- and 2-story plant at New Brighton, Penn., for the Beaver Refrigerator Manufacturing Co.

Plans are being prepared for the construction of an addition to the plant of the Johnson Bronze Co. at New Castle, Penn. Estimated cost, $85,000.

The Barrett Manufacturing Co., manufacturer of chemicals, Philadelphia, Penn., has awarded the contract for the construction of a reinforced-concrete and brick addition to its plant on the east side of Bermuda St. south of Tucker St.

The Electric Storage Battery Co., Philadelphia, Penn., is building a 6-story factory at 19th and Allegheny Ave. Estimated cost, $250,00. Noted May 11.

The contract has been awarded for the construction of a 2-story packing plant for Fried & Reineman, Pittsburgh, Penn. Estimated cost, $8,000. George M. Myers, Spring Garden St., Mgr.

The Linde Air Products Co., 30 East 42nd St., New York, N. Y., manufacturer of oxygen, etc., has awarded the contract for the construction of a plant at Baltimore, Md. Noted May 18.

The Curtis Bay Chemical Co., Curtis Bay, Md., has awarded the contract for several additions to its plant. Estimated cost, $1,000,000. J. P. McGovern, 27 William St., New York, N. Y., Secy. Noted June 8.

SOUTHERN STATES

The Libby Owen Sheet Glass Co., Toledo, Ohio, recently incorporated with $6,000,000 capital stock, is building a plant at Kanawha City, near Charleston, W. Va., estimated to cost, $1,200,000. A. F. Fowle, Vice-Pres. of Toledo Glass Co., interested.

The Groves Mills Co., Gastonia, N. C., plans to construct a cotton yarn mill. L. F. Groves, Pres. and H. H. Groves, Secy.

The Piedmont Mills Co., High Point, N. C., plans to construct 2 additions to its plant.

The Rocky Mount Mills, Rocky Mount, N. C., manufacturer of warps and yarns, contemplates an expenditure of $100,000 for improving and enlarging its plant.

The contract has been awarded for the construction of an addition to the plant of the Georgia Cordage Mills, Scottdale, Ga.

The Buckeye Cotton Oil Co., Memphis, Tenn., will construct a plant. Estimated cost, $100,000.

The Excelsior Oak Tanning Co. plans to construct an addition to its plant at 9th St. and Ormsby Ave., Louisville, Ky.

MIDDLE WEST

The General Tire and Rubber Co., Akron, Ohio, has taken over the plant of the Western Tire and Rubber Co., Kansas City, Mo., and will enlarge same.

The Punctureless Auto Tire Co., Akron, Ohio, plans to construct a factory at Barberton, Ohio.

The Damascus Manufacturing Co., 3447 East 52nd St., Cleveland, Ohio, plans to construct a 4-story factory near Cassius Ave. and East 93rd St., Cleveland, for the manufacture of oil specialties. Estimated cost, $75,000.

The Lederer Furniture Co., Rose Bldg., Cleveland, Ohio, plans to construct a new 4-story building at Euclid Ave. and East 61st St., Cleveland. Estimated cost, $150,000.

The Pittsburgh Glass Co., Court St. and Broadway, Cincinnati, Ohio, plans to construct a plant at Cleves, Ohio.

The Wolf Lanning Co., Uhrichsville, Ohio, recently organized by G. A. Wolf and T. A. Lanning, Uhrichsville, plans to construct a clay products plant east of Thornwood Park, Dennison, Ohio. Estimated cost, $150,000.

The Toledo Storage Battery Co. plans to construct a factory at Toledo, Ohio.

The De Vilbis Manufacturing Co., manufacturer of atomizers and air brushes, plans to construct a factory at West Toledo, Ohio.

The Mazuria Clay Products Co., Uhrichsville, Ohio, recently incorporated with $100,000 capital stock, will construct a plant for the manufacture of clay products.

William Gresbach, Bedford, Ind., is in the market for machinery for the manufacture of excelsior and also desires location for such plant.

Plans are being prepared for the construction of a factory at Marion, Ind., for the Lindley Box Co. Estimated cost, $20,000. Noted Mar. 2.

The Stout, Deuckwall Manufacturing Co., manufacturer of cabinets, has awarded the contract for the construction of an addition to its factory at Salem, Ind.

The Universal Chemical Co. plans to construct a plant at Battle Creek, Mich.

The Brown & Sehler Co., manufacturer of carriages, implements, saddles and harness, plans to build a factory at Ionia Ave. and Cherry St., Grand Rapids, Mich. Estimated cost, $45,000.

The Sligh Furniture Co. will build an addition to its plant at Grand Rapids, Mich.

The W. D. Allen Manufacturing Co., manufacturer of belting, rubber goods and mill supplies, plans to construct a plant at West Lake and Jefferson Ave., Chicago, Ill. Estimated cost, $110,000.

The J. D. Freese & Sons Co., manufacturer of furniture, is constructing an addition to its factory at 2501 Homer St., Chicago, Ill. Estimated cost, $25,000.

The Salter Manufacturing Co. is constructing a 3-story addition to its factory on Oakley Blvd. near Northwestern Ave., Chicago, Ill., for the manufacture of furniture. Estimated cost, $15,000.

The Fond du Lac Church Furniture Co. has purchased a site at Oak St. and Oak Pl., Fond du Lac, Wis., and plans to construct an addition to its plant. William Mauthe is Pres.

The contract has been awarded for the construction of a 75x175-ft. addition to the plant of the Hoberg Paper Mill Co. at Green Bay, Wis. Estimated cost, 70,000. Noted May 25.

The North Side Yarn Mills plans to enlarge its factory at La Crosse, Wis., and install new machinery.

The Northern Paper Co., Green Bay, Wis., contemplates the construction of a sulphite plant.

WEST OF THE MISSISSIPPI

Bids have been received for the construction of a shoe factory at Minneapolis, Minn., for the T. A. Foot, Schultz & Co. Kees & Colburn, Donaldson Bldg., Minneapolis, Arch. Noted Feb. 17.

Plans are being prepared for the construction of a packing plant at South St. Paul, Minn., for Armour & Co. Estimated cost, $3,000,000. Notel Nov. 11.

The Billings Beet Sugar Co., Billings, Mont., contemplates constructing a factory at Great Falls, Mont. W. L. Lawson is Mgr.

The contract has been awarded for the construction of a factory at St. Louis, Mo., for the manufacture of chemicals for John T. Milliken & Co., 316 Clark Ave., St. Louis. Estimated cost, $100,000. Noted Mar. 23.

The Cottonseed Oil Co. of Texas plans to construct a mill at Dallas, Tex. Estimated cost, $100,000.

The Southland Cotton Oil Co. plans to rebuild its cottonseed oil mill at Waxahachie, Tex., which was recently destroyed by fire with a loss of $75,000.

WESTERN STATES

The Voorhees Fireproof Wall Board Co. plans to construct a factory at Martinez, Calif. Estimated cost, $15,-000.

CANADA

The Ha Ha Bale Sulphite Co., Chicoutimi, Que., has awarded the contract for the construction of a paper pulp mill at Bagotville, Que.

Plans are being prepared for the construction of an addition to the plant of the Grasselli Chemical Co. in Burlington St., Hamilton, Ont. Estimated cost, $18,000.

The contract has been awarded for the construction of woolen mills at Lindsay, Ont., for Horn Bros., Windsor St., Lindsay. Noted Mar. 16.

The McKinnon Sash and Hardware Co. has awarded the contract for the construction of a factory at St. Catharines, Ont. Estimated cost, $10,000.

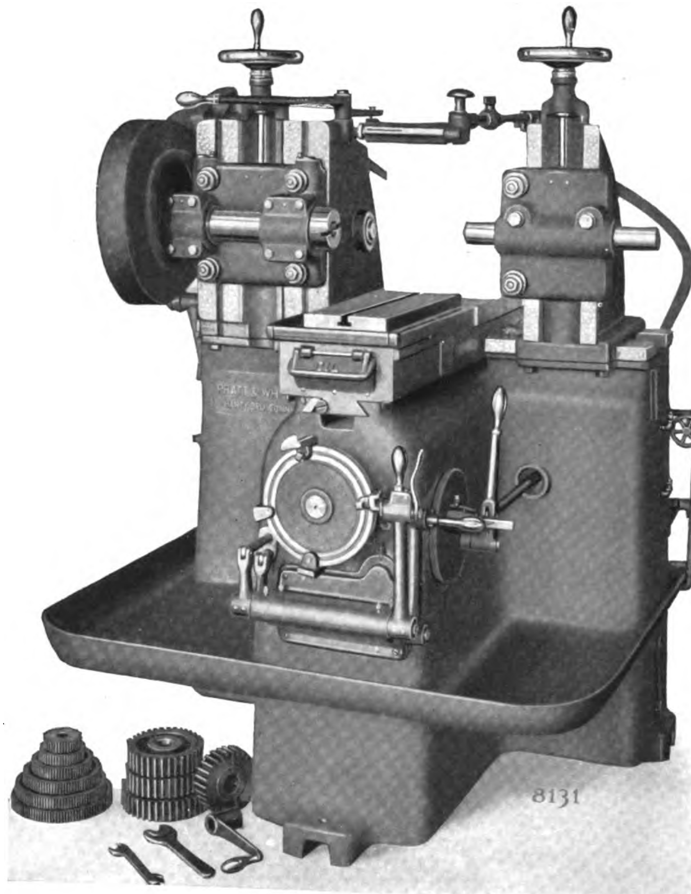
Another P. & W. Success

THE AUTOMATIC MILLER

Has been developed to meet the need for a manufacturing tool, automatic in operation and better adapted to the diversified requirements of milling work, than has heretofore been available.

Automatic Features

The table is provided with power rapid traverse in either direction automatically controlled. The table receding feature described below also operates automatically. In operation, the work approaches the cutter on the forward rapid traverse and when the cutter is about to engage the work the regular feed is automatically thrown into operation. After the milling operation has been performed, the return rapid traverse is automatically engaged and the table quickly returned to its original position for re-loading.



12-inch Automatic Milling Machine

6 to 8 Machines Operated by One Man

Automatic features reduce non-working time of machine to a minimum. With usual hand operations eliminated, machines are handled by operator without physical exertion. Practically all operator has to do is to supply machine with work. On[illegible] of from 6 to 8 [illegible]ter of work.

[illegible]feature on [illegible]ing table. This feature permits the work to clear the cutter on the return stroke, and therefore prevents marring of the finished surface. After the milling operation has been performed the table recedes a sufficient amount for the work to clear the cutter. As the table approaches the end of the return stroke, it is automatically elevated to its former position.

[illegible] shall be pleased to mail you a copy of our new [illegible]achine and describing its important features.

Talks With Our Readers

By the Publisher

"Black and White"

ADVERTISING eliminates preliminary conversations. It brings the proposition down to earth—where you know where you are at.

It enables you to buy the kind of material and equipment which you know, in advance, will give you "value received" for your money.

Very often you have listened to a salesman tell you the story of his product. Have listened to this claim and that—

Have heard how wonderful his goods were—how much better they were than anybody else's—

Have had the pleasure of hearing that no house but his own was able to turn out the class of material which he was offering—

And then, how often have you seen the color of the story fade when you asked him to put "all that in writing." Putting a proposition in "Black and White" means backing up the selling talk—means putting your claims in such shape that the reputation of the house is at stake if the goods do not live up to claims—

"Black and White" propositions can for that reason be made best by concerns who manufacture goods that will bear the light—of investigation—of publicity.

Now—

Has it occurred to you that every advertiser—every concern whose message appears in your paper—is continually talking to you in "black and white" fashion—is putting his proposition before you in a way that enables you to KNOW, beforehand, what results you can expect from any goods you may buy from him.

You can't go wrong when you deal with "Black and White" manufacturers—

Think it over.

Women and Machine Tools

By I. William Chubb

SYNOPSIS—One effect of the European War has been to show that the number of skilled men engaged in industry and in engineering is entirely inadequate to meet both civil and military needs, and all countries have attempted to fill gaps by the employment of women. This article describes what has been accomplished in this way in four prominent English machine shops.

In Great Britain some time ago it was officially stated that the number of persons engaged in the metal and chemical trades, including those employed in the ordnance factories, was about 1,900,000, of whom 200,000 were women and girls. The latter, according to a still more recent statement, number now 300,000 or more. The woman worker has long been known in some British metal-working industries. Cradley Heath and certain machine shops of the Birmingham and Manchester districts may be cited. But her presence in mechanical engineering has of late greatly extended, and even the shipyard now knows her for such branches of labor as scraping, painting and countersinking.

FIG. 1. BACKING OFF MILLING CUTTERS IN THE LATHE

The employment of women on the work of shell turning is of course easily arranged, for the processes can be divided into units each of a simple character and, given a simple machine tool, an ordinary woman does not require much in the way of training to become efficient. Such plants are in fact being run almost entirely by women. In one instance known to the writer instruction extending over four days, on the average, is quite sufficient training. With the simple tools given to them, the women usually learn before long how to set up the machines for themselves, the limit occasionally being fixed only by the muscular effort required for lifting the job or fastening it in the machine.

To cut it short, in shell work repetition methods can easily be applied. The women do one job all the time and are content, being in that respect unlike the skilled workman and perhaps even still more unlike the male youth, who, entering the shop for the purpose of "learning a trade," objects with as much vigor as circumstances allow to being kept on one process or detail for any length of time. Again, as compared with lads, women value more highly the money earned. In an engineering sense they have no past to help or to hamper them, and in many instances they can have no future; they therefore make the best possible use, at least as regards money earning, of the present.

In the production of machine tools and small tools for engineers the same conditions do not prevail. Unless the firm makes up its mind or is compelled officially to produce an extremely limited range of types and sizes of machines or appliances, the same job does not recur with anything like the same frequency as in shell making. Nevertheless, the British machine-tool firm producing tools up to a medium size and not employing women must by now be the exception. The work of the fitter, however, requiring at least a more continuous expenditure of muscular energy, does not afford so many opportunities for feminine employment. Still, women are engaged in some measure in assembling and fitting, and there are tool shops in which they are undertaking the work of scraping.

This article is concerned more directly with the work of four firms, taken merely by way of example. They are E. G. Wrigley & Co., Ltd., Birmingham, manufacturers of twist drills, milling cutters, etc.; H. W. Ward & Co., Ltd., Birmingham, who confine themselves mainly to capstans and turret lathes; the Churchill Machine Tool Co., Ltd., Pendleton, Manchester, which produces precision grinders and some special drilling machines; and H. W. Kearns & Co., Ltd., Broadheath, near Manchester, makers of drilling machines, combined surfacing, boring and milling machines and shapers.

The illustrations give a series of reproductions of photographs that are fairly representative, though it may be mentioned that a light planer is not included—a type of machine on which at least some women are employed. A broaching machine also is omitted, the writer not having met with women working on these tools.

Although one or two cases of failure might be mentioned, the work of women generally is entirely satisfactory. When once accustomed to moving parts, they rapidly get expert. Often, they apparently cannot get beyond a somewhat uncertain limit, though whether this is inherent in the sex or is simply due to an insufficient period of training is not determined. The best results seem to be obtained when a woman superintendent is provided to deal with such matters as conduct, timekeeping and dress, while as regards actual production of work the women are always responsible to the shop foreman or other male official. Commonly the women enter the works a few minutes later and go out earlier than the men, and in most instances they are spread

about the shop according to the position of the machines they have to control, though some few firms prefer to segregate the women.

One experience has been fairly general—namely, the advantage that accrues from providing a cup of tea about four o'clock in the afternoon, with in some instances definite stoppage of work for from five to ten minutes.

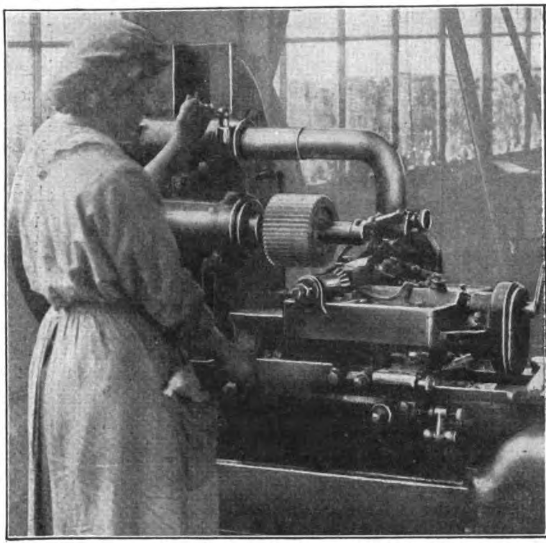

FIG. 2. MILLING CUTTER TEETH

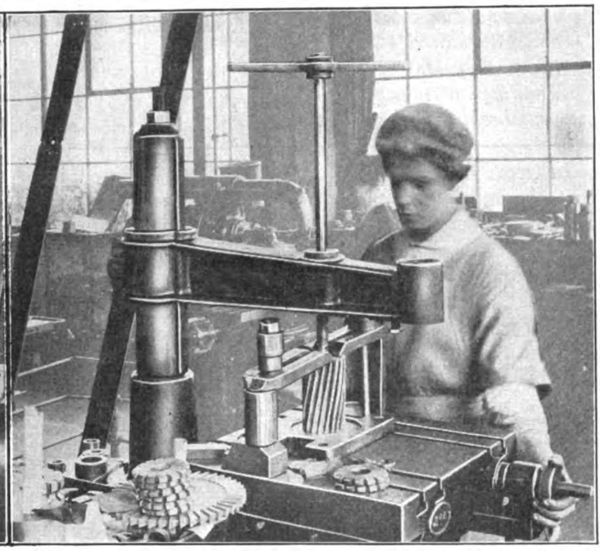

FIG. 3. A WOMAN KEYSEATER OPERATOR

Chairs and stools too are quite usual, often being taken away at the end of the woman's period when the man comes on to work the same machine. The effect of industrial employment on the health of women is in fact receiving attention from government officials with a view both to the present and to the future. Overalls and caps are commonly given and gauntlets and special aprons on particularly dirty jobs. Two sets are often provided, but the woman has to look after such matters as their washing and maintenance. As to the work undertaken by the women, an idea of this can be gathered from the illustrations.

At E. G. Wrigley & Co., Ltd., women are engaged on all operations in the production of twist drills and milling cutters, employment ranging from girls in the stores to women for viewing and inspecting, including women for floor sweeping. Drills are turned, pointed, fluted, tongued, ground, etc., the women working to micrometer and Morse taper gages, and the output is found equal to that of men and the quality good. One girl will manage two lathes, turning shanks on one and the bodies on the other. The fluting of wire sizes and of twist drills generally up to 1½ in. in diameter and grinding by women of work up to 2 in. in diameter are common.

In the cutter section the work of women includes turning, milling, backing off and relieving, slotting and grinding, all up to the capacity of the machines employed. A universal grinder is under the charge of a woman. A backing-off lathe with a woman turner is illustrated in Fig. 1; a woman engaged in milling the teeth of cutters appears in Fig. 2, while Fig. 3 shows a keyway-cutting operation. In milling, the woman does her own setting up; but, as is common, before proceeding draws the attention of the charge hand. The products include gear cutters of all kinds, angle cutters, side and face cutters, twist-drill cutters, etc. A woman is shown in Fig. 4 engaged in grinding valve-seating cutters about 6 in. in diameter, hardly an unskilled job. In the toolroom, where the nature of the work varies more, the proportion is about one woman to seven or eight men. They are engaged in shaping dies, backing off reamers, grinding hobs, running up the flutes of taps, surface-grinding flat gages, form-tool work, etc. After a time here the woman can deal with most jobs as they come along, though occasionally a setter-up is needed. The viewing department relating to the twist-drill and milling-cutter section is seen in Fig. 5. Here five girls are employed with one in charge. Work begins with the inspection of the raw material and includes complete inspection and gaging of the product, and the women are found at least as

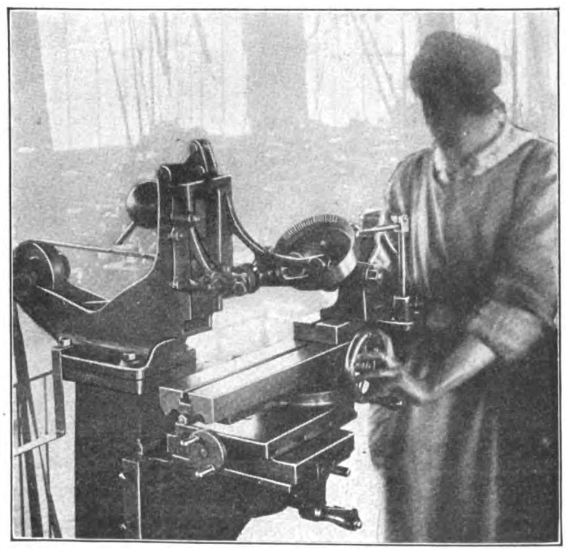

FIG. 4. GRINDING VALVE-SEATING CUTTERS

competent as men. The women have their own library, restroom and messroom and have their own representatives on the general messroom committee. When these notes were taken, out of a total shop force of about 550 some 110 were women.

At the works of H. W. Kearns & Co., Ltd., a section has been partitioned off from the main works, and the girls and women, to the number of two dozen or more, have their own entrance, with a lady superintendent in charge of cloakroom, messroom and so on. The women work 51 hr., while the general hours of the shop are 53 to the week, and it has been found necessary to check timekeeping carefully. The women are engaged on daywork, and their places are taken at night by skilled men who generally finish the jobs left by the women before proceeding with their own work. Jobs are divided into really skilled and comparatively unskilled, the first being undertaken by men and the older apprentices at night, the second class being for women. The latter, as soon as they get accustomed to the machines, so as to avoid the nipping of fingers, etc., readily get expert. In most instances they do all their own setting up under the charge hand and all their own fastening, except of course for heavy jobs, as slot-drilling large shafts. The dressmaking and milliner type of girl has been found specially suitable; when once they have undertaken a given piece of work, they can do it again without trouble, though the firm has had to do some weeding out.

Fig. 6 shows girls on small shapers. The younger girls are usually employed for this work, shaping, say, the bottom of a bracket, working from the center of the boss. In the turret-lathe department the work is largely gear blanks, and the tools are set up by the girls. They work to plug and socket gages and to solid end blocks or lengths for diameter, calipers being set to them. No screw cutting has yet been done by women, although this will be attempted. After the gear blanks are turned, they are stamped for pitch, etc., and in the gear-cutting section a girl sets the machine to these particulars, following the instructions issued with the machines and working to the indexes. Solid block gages are employed for depth on milling and shaping machines. In the drilling section, Fig. 7, are Cincinnati, Kearns and two-spindle Herbert drills. The work is here mainly to jigs. In the gear section, Fig. 8, one woman as a rule works two machines—a gear hobber and the milling-cutter type of machine. Wheels up to 3 ft. in diameter are cut, but heavier gears are kept for men at night.

It is found that the woman at the semiautomatic Bilgram bevel-gear machine can be left to herself pretty well after about three weeks, but in all cases the charge hand has to check. Occasionally a girl on a lathe will change over to a horizontal miller, and the woman on the bevel-gear cutter will change to spur gear. As to pay, piece rates prevail with time rates guaranteed. In some instances, as when the girl may require a considerable amount of help, the charge hand has a percentage of the balance. He therefore gets the benefit of teaching the girl to do the work quickly. The balance is of course the difference between the amount earned at piece rates and the ordinary time rate, and this balance or difference is divided, as stated, between the girl and the charge hand, the latter taking one-third of it. The system is found to work well. Then in regard to the gear-cutting section, in addition to the weekly rate a bonus payment

FIG. 5. INSPECTION DEPARTMENT AT THE WRIGLEY PLANT

FIG. 6. SHAPERS RUN BY WOMEN

is made for each tooth cut, whatever the size. A lengthy schedule of prices for gears of various pitches and widths is avoided, and large gears have to be taken with the small.

At the Churchill Machine Tool Co., Ltd., women are turning, drilling, fitting and grinding, internal and external. They take the place of lads rather than of men, as applied to skilled work. No young girls are employed. The women engaged are those who enter the factory with a serious purpose and have homes to keep. Several widows of men who were previously employed in the same shops and have been killed in the European War are included. The firm is very well satisfied with the result of its experiment, for under competent supervision the women are proving efficient. Women are also employed in the stores and on the sawing-off machines, cutting off steel for use in the small-tool department. In lathe work the women after one week were regularly roughing-out such details as small handwheels, bushings and pulleys, using calipers that are set to a sample. In short, they do here the work that younger apprentices would undertake. The turning foreman, an assistant to the general foreman, has the duty of training the women, who in some instances work to limit gages. In the fitting shops women undertake such jobs as tapping small parts, removing burrs and assembling. Fig. 9 shows women fitting small detail parts of the grinders. A woman will also be seen at a radial drill and on a machine for graduating the scales that register the tapers on the grinder tables. Drilling is to jigs.

In the small-tool department women are milling cutters, and they are also installed in the milling shop for such work as keyseating shafts and spindles. Women again are employed in the material stores, serving out and packing under the charge of the storekeeper, and they pack casehardening material in boxes. It is, however, in the grinding department that women have proved most successful. They control internal and external, plain and cylinder-grinding machines and work well within the half-thousandth limit. They will talk in quarter-thousandths and are in fact very skillful in the use of the micrometer. In internal grinding about one week's training is found sufficient. A woman does her own setting up for such jobs as finish-grinding internally grinder workheads and tailstocks. The foreman checks, of course, both machine and work. The kind of job that is usual in this section cannot always be regarded as repetition work, yet the firm mentions that little time is lost in transferring from one job to another.

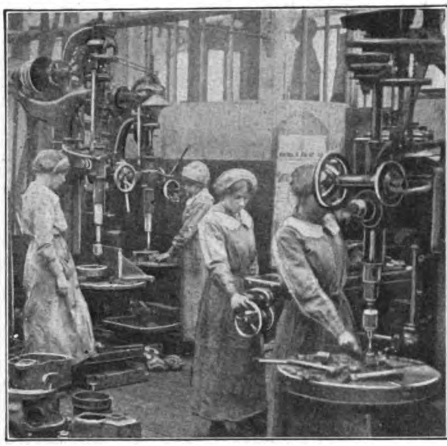

FIG. 7. DRILLING OPERATIONS CARED FOR BY WOMEN

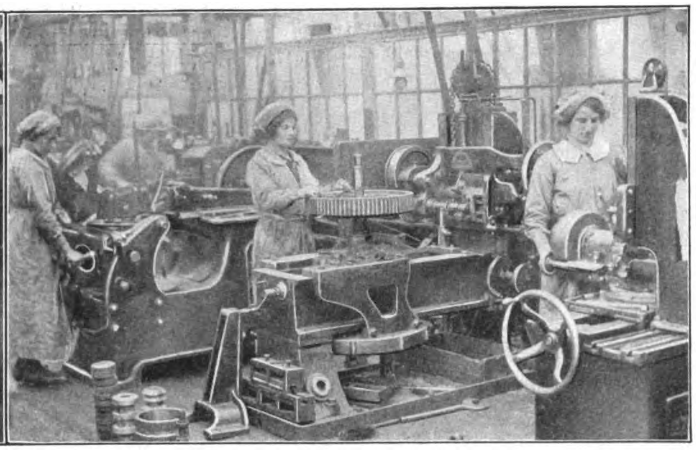

FIG. 8. WOMEN IN THE GEAR-CUTTING DEPARTMENT—EACH OPERATOR ATTENDS TWO MACHINES

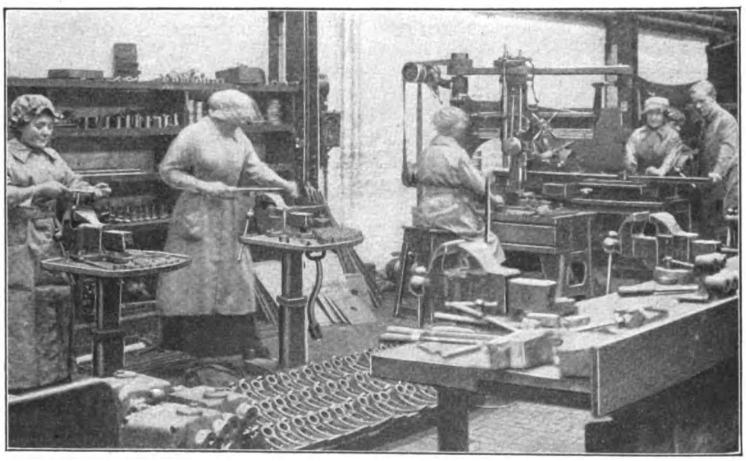

FIG. 9. FITTING GRINDER PARTS AND GRADUATING SCALES

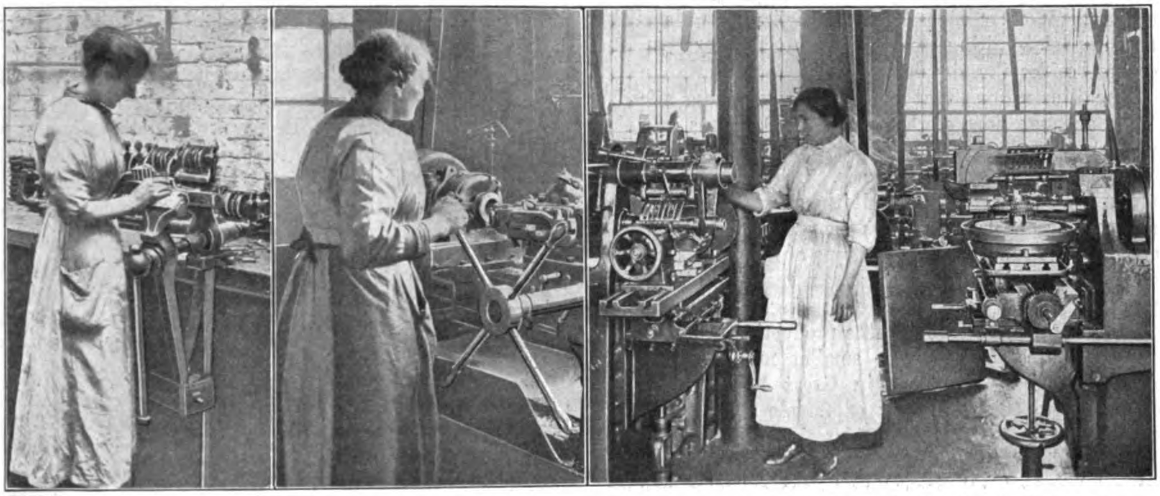
At their two works H. W. Ward & Co., Ltd., Birmingham, are employing more than 120 women. A feature is that the firm has set up a special department in which women are taught for a week or so before being passed into the shops, and this plan is now being followed by some other concerns. Besides working machines, girls are employed to act as shop clerks in the foremen's offices. The range of work undertaken can best be gathered from the illustrations of sections of the two works, given in Figs. 10, 11 and 12, which relate to the Lionel St. works, and Figs. 13, 14 and 15,

which have reference to the Bournbrook works. In Fig. 10, women are seen fitting up countershaft parts and rotary pumps. The work here is tapping, drilling and filing, besides assembling the parts and painting them, "war finish" alone being permitted for machine tools by the Ministry of Munitions. In the screw-machine section exceptionally good work is done, perhaps because there is more repetition than in other departments, grosses of one type of screw, pin, bolt, etc., not being uncommon. Automatics and capstan lathes of the firm's own manufacture are under the control of women, who can do their own setting up. In Fig. 12 a woman is seen working two machines—on the one side a horizontal miller using a plain dividing head and producing pinions, while on the other side she runs a wormwheel hobbing machine—two types generally operated by men.



FIGS. 10, 11 AND 12. FITTING ROTARY PUMPS; SCREW-MACHINE WORK AND OPERATING GEAR CUTTERS

FIGS. 13, 14 AND 15. WOMEN OPERATORS AT THE BOURNBROOK PLANT

FIG. 16. REST AND RESTAURANT DEPARTMENT FOR WOMEN WORKERS

In other sections of these works women are employed to circular-mill wedges for tool posts and in the toolroom in fitting work on collets after they come from the miller, in finish-turning collets to a collar gage for taper and boring to size. They also drill die-holder and turret parts to jigs, drill tool posts to marking out, drill countershaft collars, etc., a girl on a four-spindle drill undertaking drilling to jigs, reaming and tapping on turret rest parts. Another fits lubricator tubes to countershaft pulleys. Jobs not shown include boring and turning countershaft pulleys in turret and center lathes, pulleys up to say 16 in. in diameter being machined, the woman in this case fastening them herself. In the grinding shop, women work plain external, surface, ring and internal machines.

Fig. 13 shows a part of the inspection department at Bournbrook, a woman gaging with a micrometer the parts required on turret and capstan lathes produced by the firm. In Fig. 14 the woman is drilling friction rings to jig, and Fig. 15 shows a turning operation

relating to stops for cross-slides and saddles, which are machined from a square bar. Fig. 16 shows the type of messroom for women, as fitted up by H. W. Ward & Co., Ltd., and by other firms. Women are also employed here in working Fellows gear shapers, a woman attending both to a machine for cast-iron gears and to one producing steel gears, both of which are set up by a man. Women with the Birmingham firm are also running slot-milling machines, cutting keyways and others besides the simple type.

The illustrations that have been given here afford a fairly adequate idea of the workshop operations in which women are engaged in Great Britain for the production of machine tools and small tools. Clearly, however, they are not all-embracing; and if the whole of mechanical engineering had been taken as the province of the article, a good many more new applications of female labor would have been considered, ranging from marking off to such processes as acetylene welding, brazing, the building up of rotors for steam turbines, the production of aëroplanes and of course many of the smaller munitions details. Any engineering employer in Great Britain who has doubts as to the possibility of female labor can often get them set at rest by consideration of official photographs. The Ministry of Munitions has a collection of several hundred, all, according to the official announcement, "indexed and arranged under the trade or operation which they represent; they are at the service of firms considering the dilution of labor and can be examined at the offices of the ministry." The illustrations to this article, having been specially taken, form no part of these official photographs.

South American Trade

By Anthony Brown

I have noticed on your editorial page in several recent issues discussion of the question of American manufacturers entering the South American field. Having a number of notes made at the time I was engaged in furthering American trade in South America a few years ago, I append them herewith, as they may be of interest in this connection:

This point should be emphasized here: A branch manager or representative should speak the language—Portuguese for Brazil, Spanish for the other countries. How much business would a German manufacturer do if he sent to the United States a representative who spoke only German and who was loaded with advertising matter in the same tongue?

We Americans are notoriously wretched linguists, and our attitude is well illustrated by that of a fellow-traveler encountered in Peru, who protested: "You are making a great mistake in speaking French or Spanish or any other foreign language. Speak English only. Then all the others will have to learn it, and it will become the world language!" This course is not recommended to him who would do business in South America. Of course, there are many English-speaking people with whom business can be done; but to be in an unassailable position to do business permanently, you must reach the citizens of the country.

Attractive advertising matter should be prepared in the proper language and designed to appeal to the prospective buyer in the country where distributed. His attitude of mind is somewhat different from that of our purchasers at home.

All samples, drawings, etc., should be especially designed to catch the eye of the nontechnical buyers, the majority being of this type. A blueprint or line drawing means little to the average man, but a handsome picture in colors, a clever working model, souvenirs that bring out the value of the article for sale—all count heavily.

Especial stress should be laid upon the appearance and social qualifications of those who would do business with the government officials. Proper introductions are very valuable, especially good letters to prominent persons.

A suggestion is here offered that has been made to several firms, and that is to ransack the American technical schools and colleges for Latin-American students, with a view to securing some of the better ones at graduation, training them for a year or two in the shop and sales ends and then sending them out to Latin-America to "push the line" in a way that only a representative with this equipment is prepared to do.

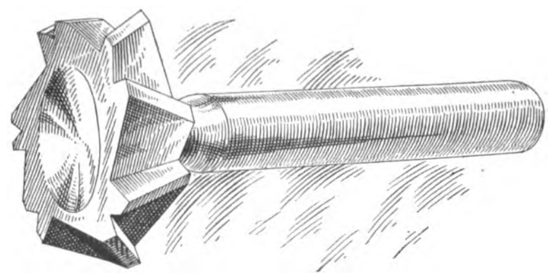
A striking example of what results may be obtained by this course is the case of a young Colombian of fine old Spanish descent, a graduate of an American college. He entered the employ of a large wire-fence firm, and after a short training in both the shop and sales departments he started for South America to introduce the fencing. In Chile alone he placed agencies and secured guaranteed orders for at least $50,000 worth of business per year, while in Argentina, where I met him a couple of months later, his prospective business was already over $100,000.

Reducing Keyway-Cutter Cost

By J. E. Brackett

The wear on an ordinary cutter makes the cost of cutting Woodruff keyways high enough to cause the department head much thought.

The cutter shown has proved itself to have a life at least twice as long as that of an ordinary cutter, probably due to the fact that the shearing effect of the tooth not only eliminates chatter, but also seems to hold



SPECIAL KEY CUTTER

the cutter to size much longer than is the case with ordinary straight teeth. The cutter is made with the teeth cut at 25 deg. to the center, right and left hand, and this angle by experiment seemed to give the best results.

By making these cutters in one long bar, then parting them off to the correct width and welding the cutter proper to a cold-rolled steel shank, the cost of making can be considerably reduced.

Measuring Screw Threads in the Small Shop

By John H. Van Deventer

SYNOPSIS—Measuring screw threads is a task that is undertaken with uncertainty in many shops. Ring and plug screw gages are commonly used, but do not always throw true light on the existing errors. This article tells how the small-shop man can measure threads with certainty, and also points out the sources of error to be looked for.

Casey was a good Irishman and a better mechanic, and was disgusted with the loss of time in his shop when it came to fitting screw threads. There were a good many studs to drive, and it was always a matter of sort and try to find those which would go in with the proper amount of pull. Some of them would fall in like a shot in a barrel and others would not even enter the hole. So Casey rigged up a block as shown in Fig. 1 in order that he might establish a standard. He succeeded in having his screws made to fit the block, but found that tapmakers seemed to have a difference of opinion regarding the size of a half inch. "Begorry," said Casey, "what an argument them fellows would have about the diameter of the earth if they've got such a difference of opinion on a half inch!"

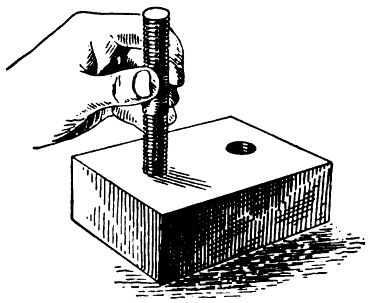


FIG. 1. THE OLD METHOD OF TRYING A SCREW IN A STANDARD HOLE STILL ANSWERS

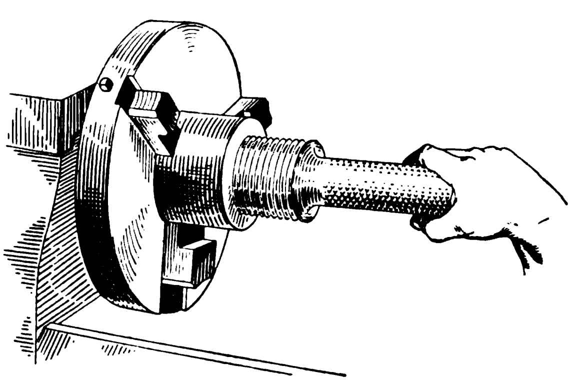

FIG. 2. CRUDE AS IT IS, THE SCREW PLUG SEEMS TO HAVE A MONOPOLY ON THREADED HOLES

This variance in the sizes of taps exists for the simple reason that the learned bodies mentioned in the article on page 1017, when establishing the various screw thread standards, did not complete their job and also establish a set of maximum and minimum limits on them. But the matter of importance and interest is not what these gentlemen did *not* do but what the small-shop man must do in order to be sure that threads will fit the holes for which they are intended.

There are twelve errors which may creep into the thread of a nut and there are twelve similar errors which may creep into the threads of a screw, so all together we have twenty-four reasons why one will not fit the other. These, for the sake of clearness, are arranged in the accompanying table.

Making the outside and root diameter of a screw too small will not affect the fit unless these errors are excessive. Conversely, making the root and outside diameters of a nut too large often helps things instead of harming them. When the reverse is true, however, and the outside diameter of a screw is larger than the root diameter of the nut, there is trouble. This is usually what is encountered when one tries to screw a V-thread into a U. S. S. nut. The way to overcome this difficulty is to keep the V standard out of the shop. Sometimes the wrong thread angle on either screw or nut makes a defective fit which cannot be noticed because the pitch happens to be right. A case of this kind is shown in Fig. 3, where there is

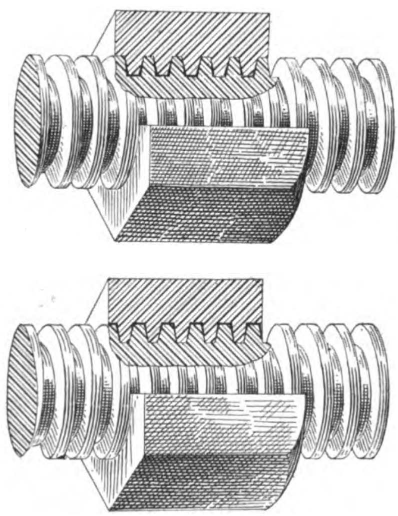

FIG. 3. THE RIGHT PITCH, BUT THE WRONG THREAD ANGLE FOR A PERFECT FIT

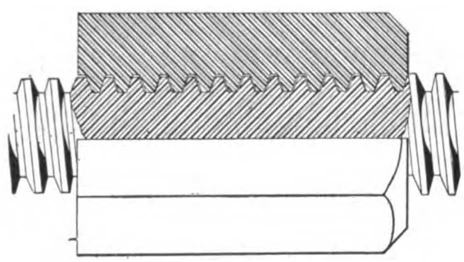

FIG. 4. THE SCREW TOO SMALL, BUT BINDING IN THE LEAD, SO THE CONTACT IS LIMITED

contact at the extreme corners of the threads and consequently no shape but a very poor fit. Another poor fit is shown in Fig. 4, in which the lead is stretched, apparently making a tight driving fit, but in reality having contact only on the surfaces of two or three threads.

Sometimes the pitch of both nut and screw may be right, the lead right, the angle right, the outside and root

ERRORS IN THREADED WORK

Diameter (outside)	Too large Too small
Diameter (pitch)	Too large Too small
Diameter (root)	Too large Too small
Angle of thread..............	Too large Too small
Pitch of threads.............	Too large Too small
Lead—Not uniform	
Burrs and bruises	

diameters right, but everything all wrong nevertheless. This is because of the vital dimension, which cannot be seen and which is hard to measure, which is known as the pitch diameter. A case of this kind is illustrated in Fig. 6 and would give a very shaky fit, while an error of the opposite kind in which the threads of the screw were too thick would make it impossible to enter the screw. Fortunately for most small-shop purposes, it is safe to assume that the angles of threads on purchased taps and dies are correct. Also for this class of work it is quite possible to test the lead of a screw by means of a gage such as shown in Fig. 7. These gages run from 2 to 4 in. in length, depending on the fineness of the pitch, and a little experience will make the shop man an expert in their use.

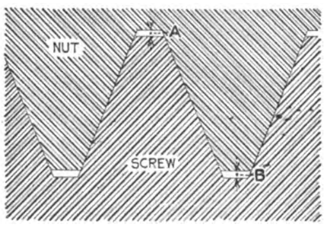

FIG. 5. SOME VARIATIONS IN DIAMETER ARE HARMLESS

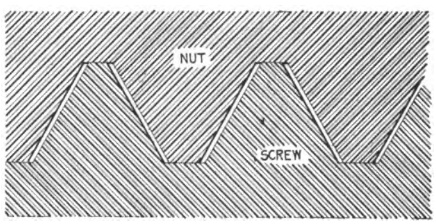

FIG. 6. THE PITCH RIGHT, THE LEAD RIGHT, THE ANGLE RIGHT—BUT ALL WRONG, NEVERTHELESS

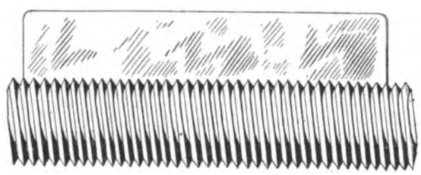

FIG. 7. TESTING THE LEAD WITH A SCREW PITCH GAGE

Limit thread gages for testing pitch diameters form a means of inspection that is absolutely decisive. These are used on precision work, but an individual gage is required for each diameter and pitch, which usually limits their application to shops in which a large quantity of pieces having a limited number of thread sizes are handled. For average small-shop requirements, which will not call for measuring every screw used, three methods of measuring pitch diameter are available—the thread micrometer, the ball-point micrometers and the two- and three-wire systems. The latter can be used with an ordinary pair of mikes such as will be found in every small shop, and will give as accurate results as any method of measurement, although a little slower than the special micrometers made for this purpose. The method of using the two- and three-wire systems is indicated in Fig. 9. Wires are taken of proper size and measurement made across their outside diameters when laid in opposite thread spaces. The micrometer readings are compared with a table which gives the reading in terms of pitch diameter. Tables for this purpose for all of the standard threads can be found in the "American Machinist Handbook," pages 30 to 40.

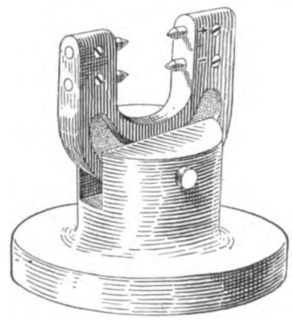

FIG. 8. LIMIT THREAD GAGES FOR TESTING PITCH DIAMETER

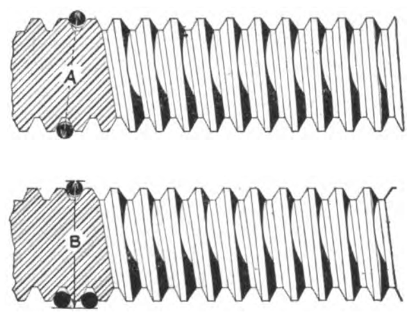

FIG. 9. MEASURING THREADS BY THE TWO- AND THREE-WIRE SYSTEMS

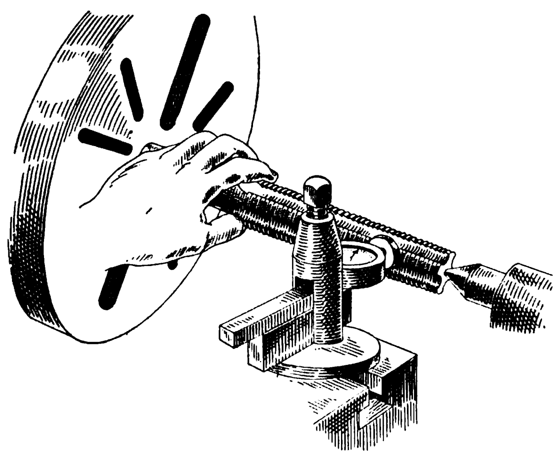

FIG. 10. TESTING A TAP FOR WARP BETWEEN LATHE CENTERS

While the thread angles on taps may be assumed to be correct, there are other things which it would be well to check up as soon as the taps come into the shop. A set of inspections for checking up taps are illustrated in Figs. 10 to 13. The first illustration shows a tap placed between lathe centers and being tested for warp and eccentricity due to distortion in hardening. Fig. 11 shows the

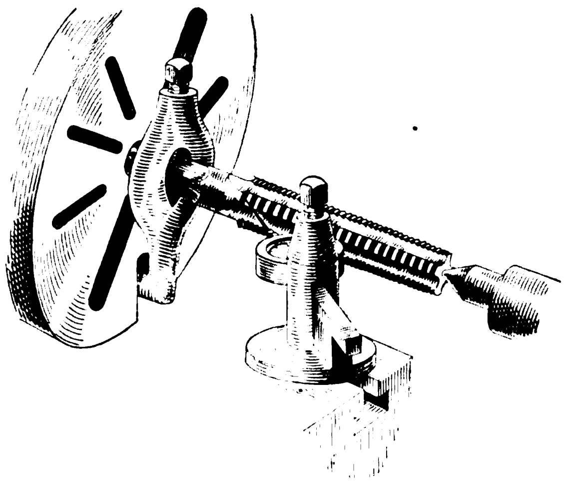

FIG. 11. COMPARING THE LEAD OF A TAP WITH THAT OF THE LATHE LEAD SCREW

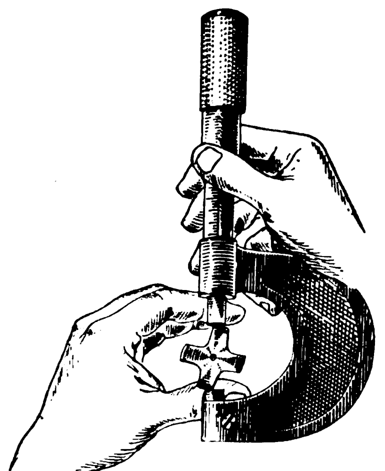

FIG. 12. MEASURING THE OUTSIDE DIAMETER OF THE TAP TO INSURE A FULL ROOT DIAMETER

means of comparing the lead of a tap with that of the lathe lead screw, which will indicate an error in the tap provided the lathe screw itself is accurate. An indicator is held in the tool post with its needle against one side of the tap face, the lead screw is engaged, the operator turns the belt by hand and eases off on the indicator needle from space to space, observing any fluctuation as the needle comes to rest on successive flutes. If the tap lead is right and the lathe screw lead is right, there should be no variation on the indicator.

The outside diameter of the tap must be large enough to insure a full root diameter of the tapped hole. This is measured with a pair of "mikes" as shown in Fig. 12. The final test is that of the pitch diameter, which is made as shown in Fig. 13, and which has been explained in the description of the three-wire system. If a tap passes these four inspections satisfactorily, it is a pretty good tool as far as accuracy is concerned. To insure that the bolts, screws and studs that are purchased outside will fit properly into threads made with such a tap, it is advisable to inspect one or two of such studs, bolts or screws in every one hundred by means of running them into a block such as shown in Fig. 1. This, called selective inspection, will call attention to batches of screws which are running over or under size, in which case a further inspection of each screw in that batch may be made if desired before returning them to the maker. It is advisable for the small-shop man to protect himself in buying such screws by submitting a similar gage at the time that he gives the order.

Dies are best inspected by examining the work that comes from them. Do not, however, make the mistake as did one small-shop man of testing an adjustable die

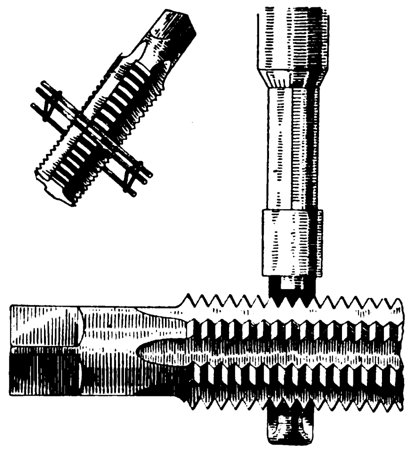

FIG. 13. MEASURING THE PITCH DIAMETER WITH "MIKES" AND WIRES

with stock that was larger than that intended for the chasers that were used. The chasers were supposed to cut twelve threads to the inch, but after the work came out of the die he could find but thirty-five threads in 3 in. One of them had disappeared mysteriously, and he is still hunting for it!

Lifting the Shaper Chuck

By G. A. Remy

The vise, or chuck, on large shapers is heavy and, owing to its form, difficult to lift and place in position on the shaper table. Recently I saw three men put a large chuck in position without trouble, in the following manner:

Before the chuck was removed from the shaper, a piece of iron pipe was clamped between the vise jaws, the ends of the pipe protruding from the chuck far enough to furnish a grip. A man on each side lifted the chuck and, thanks to the pipe, easily held it in position over the table while a third man inserted the binding bolts and wiped away any chips that had fallen from the chuck to the table.

This is a simple method, but one not generally practiced. Besides avoiding the strain on the men in lifting, the machine is saved many hard knocks, which generally result when the men lifting the chuck have a poor grip. This idea is not original with me. I have seen it used by shaper hands.

Cast-Iron Punches and Dies for Car-Fender Details

By Robert Mawson

SYNOPSIS—In the punch and die used in making the carrier arm two operations are performed. The bar is first placed on the die, and the end of the part is flattened with the punch. The bar is then slid against a stop in another position of the die, and a depression is formed with a pin in the punch. The tool for forming the side hanger is fitted with an equalizing device.

On pages 894 and 978 are illustrated some of the punches and dies designed and used by the Narragansett Machine Co., Providence, R. I., in making parts of car fenders. In this article other similar tools are shown. Their interesting feature is that cast iron is used in their manufacture. They are not machined, as the scale on the faces provides a hard wearing surface. These tools, as well as those illustrated in the previous articles, are good examples of this type of punches and dies. The stock is heated before the various bending or forming operations. The rate of production is also given in the articles. Some of the simpler machine-steel or iron fundamentals on car fenders are here illustrated as made with cast-iron punches and dies. Many companies are using punches and dies of either machine steel or tool steel for similar work. With tools of these materials, expensive machining operations are necessary. The block of steel must be machined to the desired contour; and when this shape is somewhat complicated, the work demands high skill and is comparatively slow.

When the tool is made with a combination of machine-steel shank or base and tool-steel forming element, the task is even more difficult. The machine-steel part must be machined. The tool-steel element must also be machined to the required contour. Then the latter must be hardened and ground. This is often a difficult operation, as there is danger of cracking during hardening. The grinding takes a long time, as much of the surface must be finished by hand with an oil stone. The two elements are fastened together with screws and dowels to form the completed punch or die.

When the tools are of cast iron, most if not all of this machine-shop work is avoided. Patterns are built up to agree with the design furnished by the drawing office. Castings are then made from these patterns and in most cases used without any machining whatever. Where machining is performed, it is only on the shank, to make it fit the punch press. The hard skin surface left on the castings is an advantage, as it resists wear that would be caused by the punch and dies coming in contact with the bar being bent or formed.

On the tool used in forming the carrier arm two operations are performed. The bar is first flattened with two flat surfaces on the punch and dies. The flattened bar is then placed in a depression on the die and the punch fed down. This punch is made with a button and, as it is forced down, forms a hollow in the carrier arm.

The next tool is designed to bend the end of the pilot-board bracket into a circle. This is done by dropping down a loose circular bar over the heated bracket; and when the punch is fed down, it bends the piece around the guide bar. The last tool is provided with a fulcrum pin on the punch. This is an advantage in forming long parts from rough stock, as it allows the tool to conform to any variation in thickness.

It will be seen from this and also the previously mentioned articles how elements may be formed by the use of cast-iron dies. Other parts can be made with similar type of tools and their advantages completely utilized.

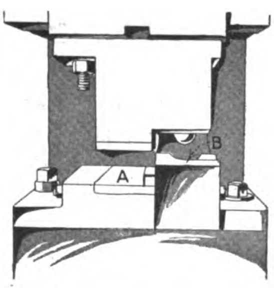

FIG. 2

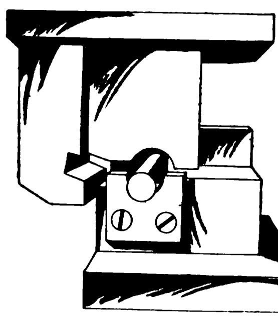

FIG. 4

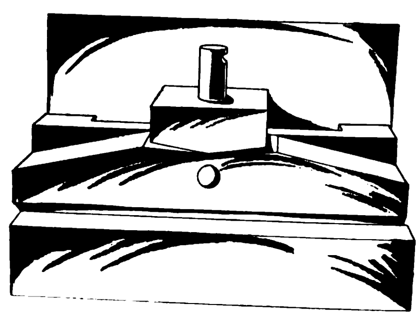

FIG. 6

CAST-IRON PUNCHES AND DIES FOR CAR-FENDER DETAILS WITH WORK SHOWN IN POSITION

FIGS. 2 AND 2-A

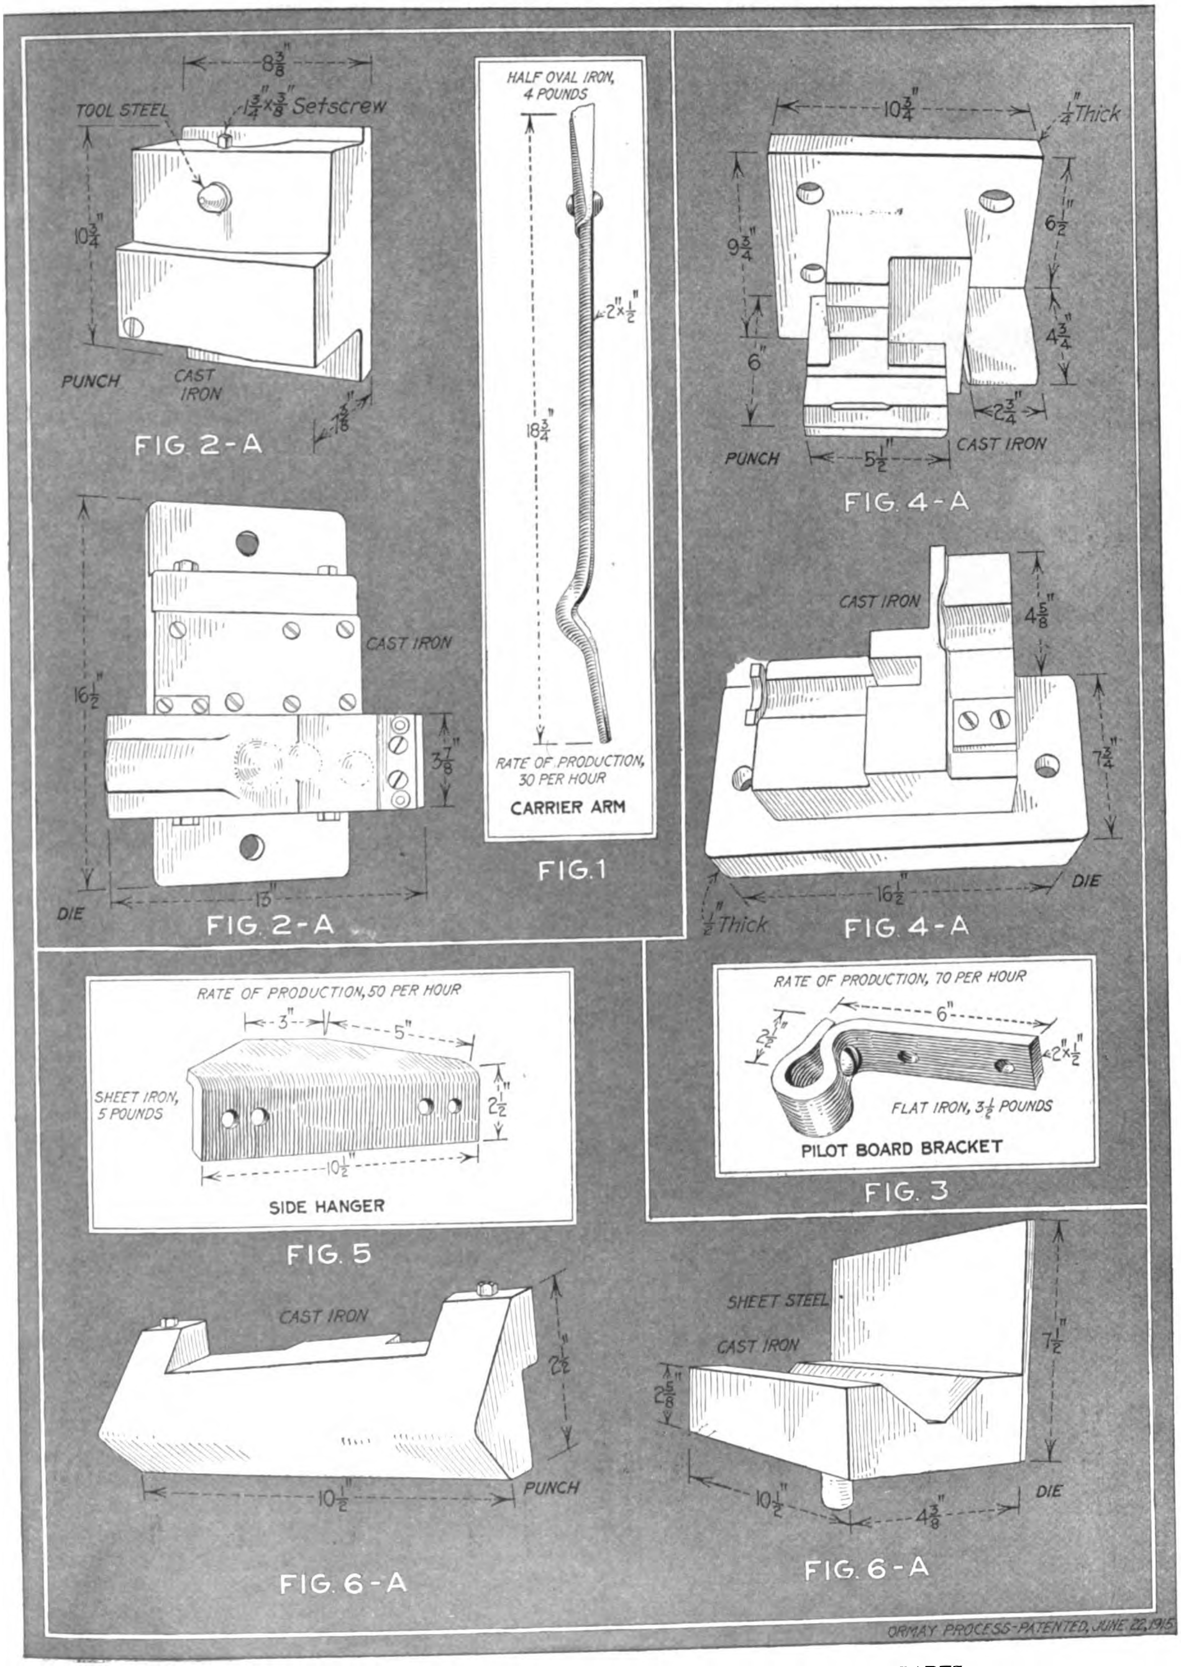
Operation—Forming the carrier arm to the contour shown in Fig. 1. The bar is first placed on the die at A and the end flattened with the punch. The bar is again heated and placed on the die at B. When the punch is forced down, a depression is formed in the bar, as shown.

FIGS. 4 AND 4-A

Operation—Bending pilot-board bracket, Fig. 3. The heated bar is placed over the rod in the die. When the punch is forced down with the press, the end is bent over. A rivet is placed in position, as shown, in a subsequent operation.

FIGS. 6 AND 6-A

Operation—Bending side hanger, Fig. 5. The plate is placed on the die, being located by the stop plate at the rear. The punch, forced down, bends the parts to shape. It will be observed that, as the part is long, the punch can fulcrum on a pin to form an equalizing means.



DETAILS OF CAST-IRON PUNCHES AND DIES FOR CAR-FENDER PARTS

Balancing Ways with Drilling Attachment

By E. V. Allen

The balancing ways shown in Fig. 1 were made by the Western Foundry and Machine Works, Topeka, Kan., some 25 or 30 years ago. The drilling-machine attachment is very handy for drilling weight holes. An

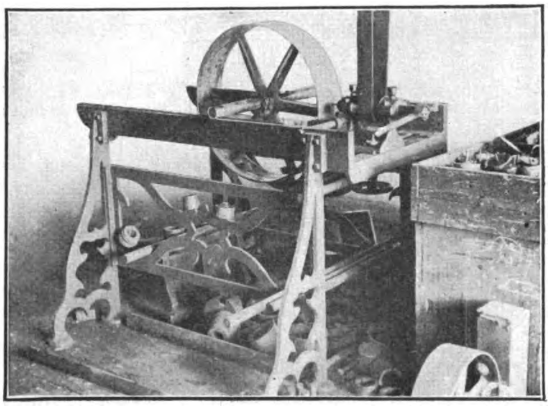


FIG. 1. BALANCING WAYS WITH DRILLING ATTACHMENT

assortment of weights is kept close to the machine, and it is but a matter of a few minutes to find a weight that will balance. A special set of holding jaws, shown more clearly in Fig. 2, holds the pulley while drilling

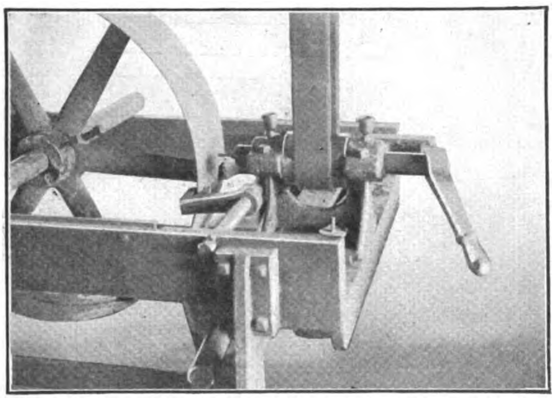

FIG. 2. CLOSE VIEW OF PULLEY-HOLDING JAWS

into the rim. These jaws slide on a crossbar and simply hook over the rim of the pulley. The drilling spindle is fed in or out by a hand lever. The entire drilling head has a cross-adjustment intended for use on very wide pulleys where more than one hole has to be drilled.

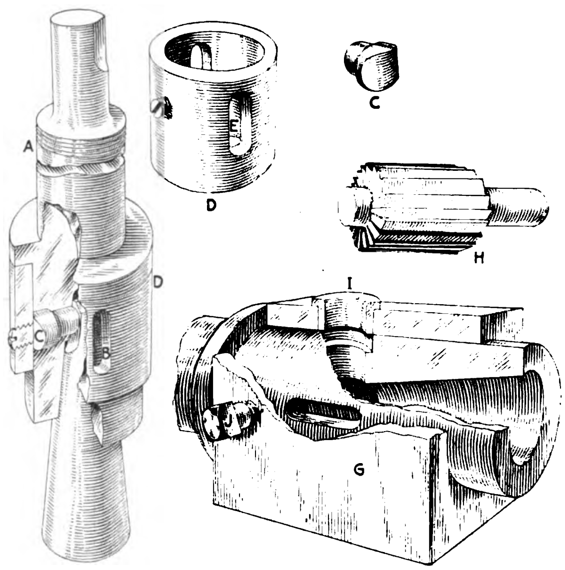
Repairing Drill Spindles

By Paul Cyr

After some years of hard usage 20 drills were so worn in the tang slot *B* in spindle *A* that it was almost impossible to hold drills in them. To repair them, I worked out the following scheme, which has proved successful after three years of hard work, with the advantage that a spindle can be repaired at a small cost, should the same trouble again arise.

I made a fixture *G* with removable bushing *I*, in which the spindle was inserted. Screw *J* was tightened, to steady it, and the bushing was drilled through at *B*. It was then removed and the counterbore *H* inserted in the hole and counterbored deep enough to take the head of the plug *C*, the plug being flush with the outside of the spindle. The spindle was turned and the operation repeated on the other side.

The plugs *C*, of hardened tool steel, were then inserted in the holes. The collars *D*, of machinery steel, were



REPAIRING DRILL SPINLDES

made and bored to fit the spindle. The slots *E* were cut for the drift and a threaded hole for a screw to hold it in position. The collar was put on the spindle and the slots brought to correspond with the slots in the spindle. The spindle was spotted for holding the screw and the screw tightened down. The plugs *C* are of sufficient length to bear against the tang of a drill or collet and, should they become worn at any time, can be removed and new ones put in place in a few minutes.

Fitting Dovetailed Patches

By Alfred Strother

A dovetailed piece is a convenient means of patching or piecing on metal-pattern work, etc. When driving, if the male member is a little large or fits imperfectly, the edges are apt to curl, buckle, turn up or tear out. This is especially true if the "tail" is thin.

A simple stunt that prevents this trouble is to back up the two pieces against each other when ready to drive. If the size and shape of the work permit its use, the bench vise is handiest for this; if not, C-clamps will serve. When the dovetail is fitted so that it will enter, begin to drive, then clamp tight enough to hold securely and drive. If there is any crowding, the male will stall, which can be easily remedied; and the misfit is found without tearing out the slot or bruising and curling the edges. The surfaces in sliding contact should be smooth, and a little oil should be used.

Making Wire Guards for Electric Incandescent Lamps

By Ethan Viall

SYNOPSIS—While the wire guards for incandescent lamps are made in a large variety of forms, the general principles of manufacture apply closely to all. The factory where this article was obtained turns out huge quantities of guards of all kinds, but only the more representative or unusual methods are shown.

Disregarding the various individual forms of incandescent-lamp guards, they may be broadly divided into two classes—those which are locked on and cannot be removed, except with a special key or tool, and those which can be put on or removed with the fingers. With the rapidly increasing use of tungsten and other valuable lamps, some protection against easy theft is imperative. A good locking type of guard not only protects the bulb against breakage to a large extent, but also from unlawful removal. The McGill Manufacturing Co., Valparaiso, Ind., makes a large variety of both kinds, the former being marketed under the name of Loxon. Some of the principal methods employed in its factory for quantity production will be described in this article.

A few representative forms of guards are shown in Fig. 1. *A, B* and *C* are handled guards, for drop lights, trouble hunting or any place where a portable light is desirable. Some of these are provided with a hook by which they may be hung from shelves, nails or any projection. The guards at *D* and *E* are the kind that may be put on or taken off with the fingers alone. Those at *F, G, H* and *I* are of the Loxon type, the last one being fitted with a reflector. All of the last-indicated guards are locked by means of a small screw having a triangular-shaped head set into a socket, so that the screw cannot be turned except with a special form of socket wrench or key. This forms a simple and effective lock that is very difficult to operate without the proper means.

The basic wire in the common guards will run from 13 to 17 gage. The "ribs" vary in size and shape according to the form of guard. Two of the different shapes of ribs are shown at *A* and *B*, Fig. 2. The "hoops" may be made of sheet metal, straight wire bent to circular form, or corrugated, as *C* and *D*. The wires *E, F* and *G* are used for "cushions"; that is, on some of the guards these wires are so placed as to prevent the guard from contacting with the glass of the lamp and are so strung as to have a cushioning effect. These wires are wound on a long mandrel, then cut as at *E* and next bent to the form shown by the last two. Two

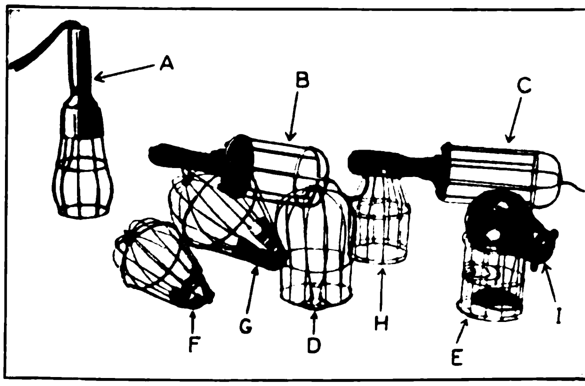


FIG. 1. SAMPLES OF WIRE LAMP GUARDS

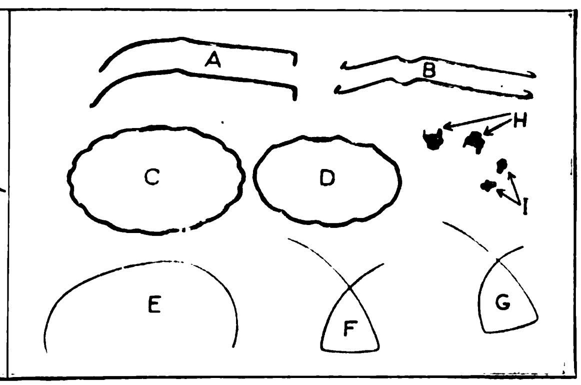

FIG. 2. SOME OF THE PARTS USED

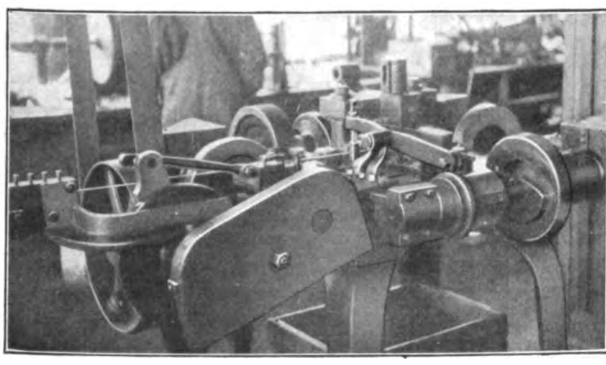

FIG. 3. ONE OF THE WIRE-FORMING MACHINES

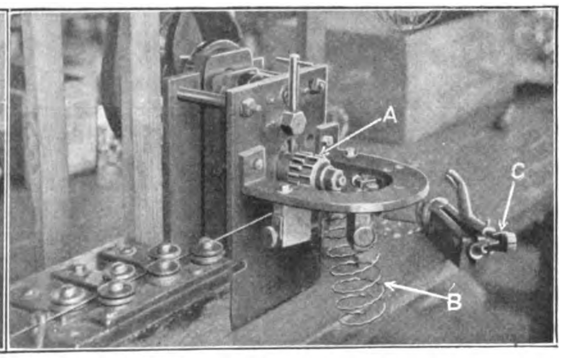

FIG. 4. MACHINE FOR CORRUGATED RINGS

screw sockets for the Loxon type are illustrated at *H*. The screws, with three-cornered heads, for these sockets may be seen at *I*.

Some of the ribs on certain portable or other guards are not bent at all, but are made from short, straight pieces of wire rod. These are shouldered or threaded on the ends as desired. Some of the ribs are quite complicated in form. However, the majority of the ribs wound, the operator pushes the guide along the bar *C* by means of the handle *D*. The mandrel has a slot in it running lengthwise, deep enough for the insertion of one jaw of a special pair of shears. After the mandrel is full, the shears are worked down this slot, cutting the wire as it goes. This makes short pieces like the one shown at *E*, Fig. 2. The special shears for this work are shown in Fig. 6. *A* is the jaw that is placed

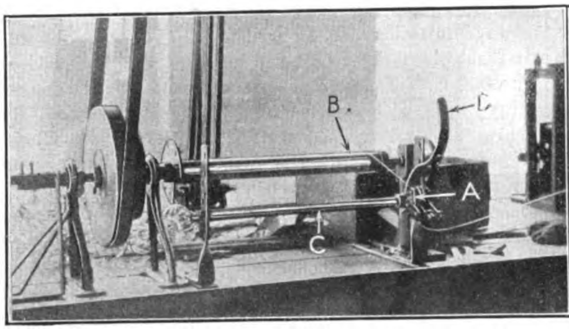

FIG. 5. WINDING WIRE ON A MANDREL

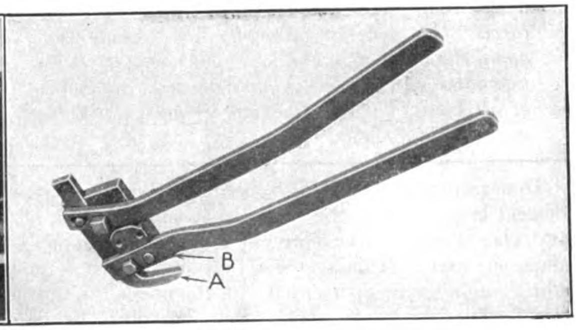

FIG. 6. WIRE-CUTTING SHEARS

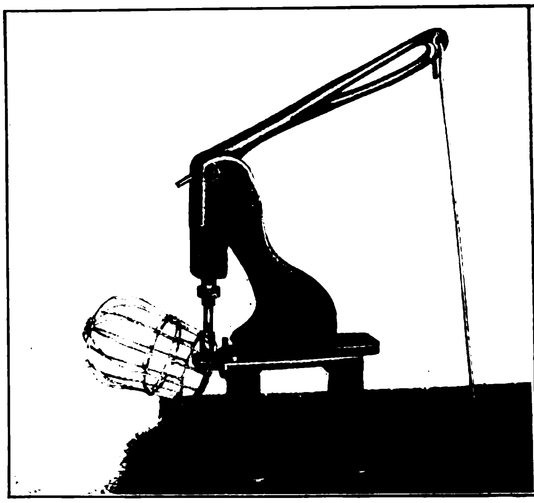

FIG. 7. SMALL WIRE-CLINCHING PRESS

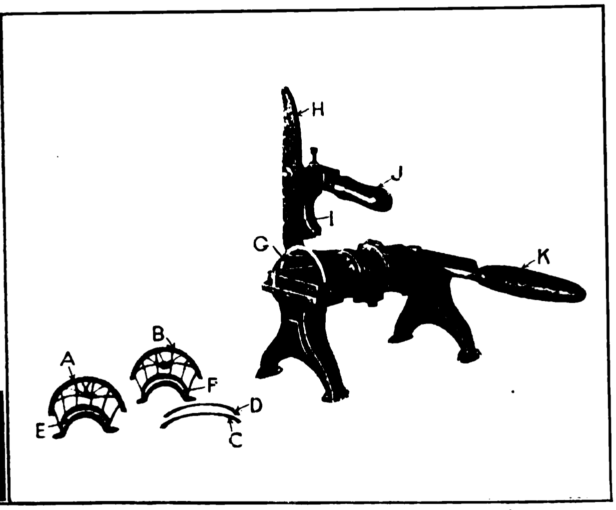

FIG. 8. SPECIAL CLINCHING MACHINE

are made on standard four-slide wire-forming machines, like the one shown in Fig. 3. These take the wire from the reel, bend, cut and drop the ribs into a box. On most of the work, only three slides are used. The machines run at about 75 strokes per minute.

The corrugated "hoops" are made in the machine seen in Fig. 4. The wire feeds through the straighteners at the left and in between toothed rolls, geared together, as at *A*. After passing through the rolls, the wire strikes a deflector that causes it to curl against another, and so on, the result being a spiral, as at *B*. The setting of the deflectors determines the diameter of the spiral formed. A cutter at *C* cuts the wire into rings. While this cutter is shown swung out away from the work, it can be swung in so as to clip the wire as it feeds down.

The fine spring-wire cushions previously referred to are wound on a mandrel, Fig. 5. The wire feeds from a reel into a set of friction rolls at *A* and from there onto the revolving mandrel at *B*. As the mandrel is in the slot and pulled along as the upper one *B* is worked by means of the upper handle.

The assembling methods are almost as varied as the forms of the guards. Some are simply "hooked" together by hand and are clinched with small hammers. Others are assembled and then the hooks clinched, as in Fig. 7. The rams of these little bench presses are worked by a foot treadle, so that the operator has her hands free to manipulate the work.

One of the Loxon type of guards is made in two semicircular parts *A* and *B*, Fig. 8. The hoop in this case is made of two semicircular pieces *C* and *D*, which are perforated for the insertion of the rib wires. The collars are made of sheet metal, formed as shown at *E* and *F*. The ends of the ribs where they are inserted in the holes in the collars are first bent at right angles. The halves of the guard are assembled by hand substantially as indicated by the parts shown. A half is placed in the clinching device, as indicated at *G*. The

part H is then swung down on the work, bringing part I snugly around the ends of the ribs where they enter the collar. The lever J operates the locking latch. With the work locked in, the lever K is pulled; six slides move in their individual slots under the projecting ends of the ribs inside the collar and bend them close up against the inner surface. This securely clinches them in place.

The screw sockets are clinched, or staked, into the locking collars in small hand presses, Fig. 11. One is shown in clinching position at A. About one gross per hour is turned out on each of these little presses.

Nearly all the guards are tinned. This is done in the usual dipping way. Fig. 12 shows an operator holding a guard in special tongs ready to dip it into the melted

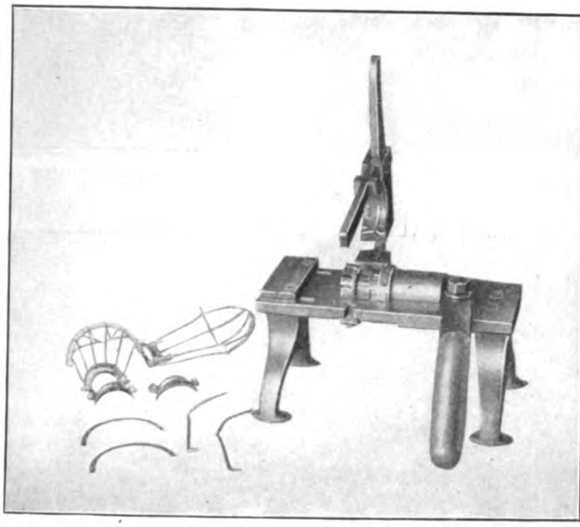

FIG. 9. ANOTHER VIEW OF CLINCHING MACHINE

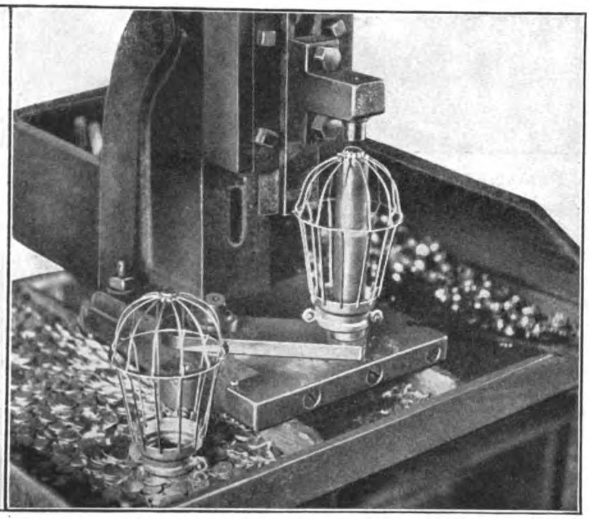

FIG. 10. CLINCHING BUTTONS ON THE WIRE ENDS

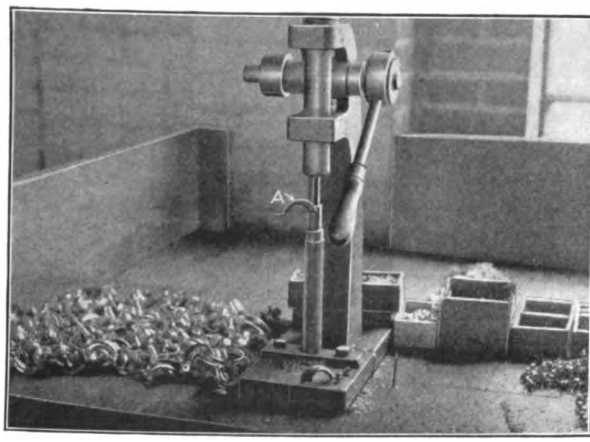

FIG. 11. CLINCHING SCREW SOCKETS INTO THE COLLARS

FIG. 12. TINNING THE GUARDS

Another view of this same fixture is given in Fig. 9, together with the parts differently placed, so as to give a good idea of the work and mechanism. A large number of these machines are used for the different guards having sheet-metal locking collars. On the average guard an operator will turn out about four gross in nine hours.

On some forms the outer ends of the ribs are held in a sort of spider, or "button," as it is called. The ends of the ribs are placed in one of these buttons, and then the guard is placed over a slotted post, as in Fig. 10. A pressure on the foot treadle of the press clinches the projections of the button tightly onto the rib ends. The post is placed on a swinging arm, so as to be easily swung away from under the press ram for loading or unloading. About eight gross will be turned out by a good operator on one of these presses.

tin. After being tinned, the guards are placed on rods, as shown, just back of the workman.

Since the tinning is done after the guards are completely assembled, the tin gets into the threads and screw sockets. This is remedied on the apparatus seen in Fig. 13. A small gas jet is made so as to shoot a flame up into the socket placed above it. Six or more of these jets are made in the horizontal pipe, and the guards are laid in place. As fast as the tin melts, the operator takes the guard and with a quick jerk knocks the tin out of the threads and sockets.

Where short wire rods are employed, as in some of the portable guards, the ends are turned down so as to form a shoulder where the retaining ring goes on. This is done with a hollow mill in a lathe fitted as in Fig. 14. The hollow mill is held in the chuck at A and the

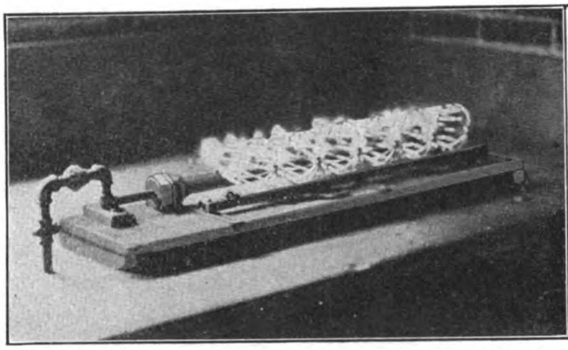

FIG. 13. MELTING TIN OUT OF THE SOCKETS ON A SPECIAL GAS FIXTURE

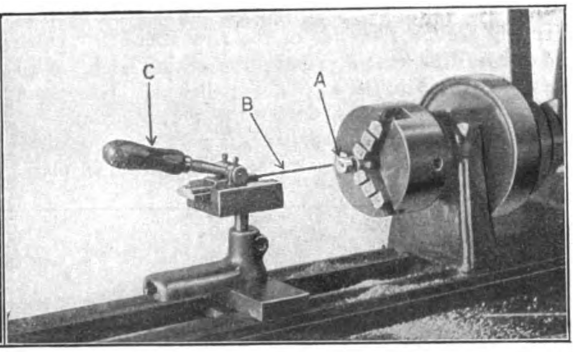

FIG. 14. HOLLOW MILL AND QUICK-ACTING WORK HOLDER FOR THE LATHE

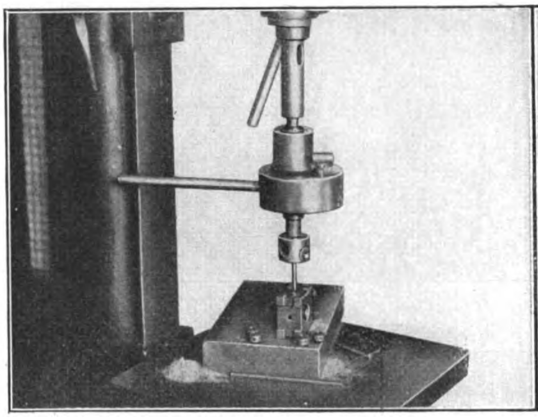

FIG. 15. TAPPING HOLES IN END NUTS WITH REVERSING ATTACHMENT

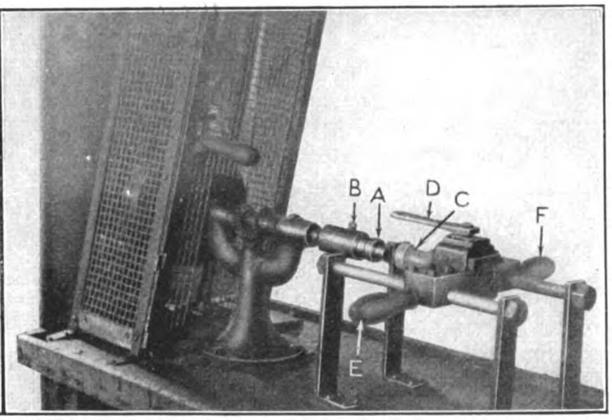

FIG. 16. SCREWING ON WOODEN HANDLES ON PORTABLE GUARDS

rod *B* fed into it. The rod is held in an eccentric-jawed vise operated by the lever *C*, which acts both as a locking lever and a handle to push the carriage with. Where the ends are threaded, a die is used in place of the hollow mill, but the holding fixture is practically the same.

Rapid Drilling and Tapping with the Aid of Small Box Jigs

On guards having ribs made of rods curved in at the ends, the buttons are made of brass, with holes drilled and tapped in them for the curved ends to screw into. These brass buttons are drilled in little box jigs, like the one in Fig. 15. When tapping the holes, an Errington tapping head is used, as shown. An operator will drill about 170 of these buttons, or top nuts, per hour, four holes each. Tapping is done at the rate of about 160 per hour, four holes each.

The wooden handles on the portable guards are screwed on in the machine illustrated in Fig. 16. The guard part is held in the spindle socket at *A* by means of the setscrew *B*. The wooden handle *C* is locked into the sliding carrier by the wrench *D*. The operator then grasps the handles *E* and *F* and pushes the handle onto the piece *A*. The spindle drive is through a regular tapping mechanism, so that forward pressure engages the drive and forces the threaded part into the handle. Retarding the work stops the spindle. The mechanism of the drive is shown at the left. It consists of three bevel gears, two facing each other on the spindle, with the driving gear between them and facing upward. The output of one of these machines is about 100 per hour, though this varies with the operator, as in all other cases of machine work.

Grinding Gages in the Miller

By Gustave A. Remacle

At the present time many plants making gages are not properly equipped for that class of work, the absence of a good surface grinder being the cause of most concern. Happily, magnetic chucks are plentiful, and it is surprising how much a miller resembles a surface grinder when equipped with a magnetic chuck.

One concern, after fixing up the bearings and spindle of an old hand miller, mounted a wheel upon the arbor in the same manner as a cutter. A handwheel was substituted for the lever, for moving the table transversely. Another simpler, though less efficient, manner of converting the miller to a grinder is to bolt a tool-post motor grinder to the overhanging arm, the bolt running through the hole where the center was formerly.

While millers may be fitted up so as to grind somewhat flat surfaces in an emergency, they do not begin to compare with real surface grinders, especially for grinding gages. One reason why these converted machines do not produce good results is that the machine is generally so badly worn that it is unfit for milling, not to mention grinding.

Designing and Drafting*

By W. Rockwood Conover†

SYNOPSIS—The relations of both engineer and draftsman to the work of drafting and to the finished drawing. The change in the quality of machine-shop labor has put new burdens on the one who makes shop drawings. Today they must be explicit and covered with details. The care, changing and issuing of prints are also discussed.

The relation of designing and drafting to efficient productive work in the shop is a vital and intimate one. Some of the important features of this relation merit consideration. Relatively speaking, there are few details of manufacture that may be said to be free from the influence, either direct or indirect, of the work of the engineer. Designing has as much to do with successful manufacturing as any other of the several processes preliminary to and connected with the actual production in the foundry and shop. In so far as the engineer realizes this basic principle in his labor, to that extent will his work prove to be successful and valuable.

It is essential for the engineer to study manufacturing conditions in the shop, in order that he may design apparatus that can be built with the greatest efficiency and economy at the same time that it fulfills the requirements of the trade or the individual customer for whom it is designed. He should familiarize himself with the tool equipment of the factory in order to avoid, as far as possible, calling for sizes and dimensions that will involve special processes on the machine floor and render the purchase or making of special tools necessary. If the purchase or making of special tools cannot be avoided in the construction of the design, the possibility of these tools being adapted to other work or to future designs is worthy of consideration.

The subject of materials and inventories should receive the engineer's attention. Each new design made should embody the use of standard commercial sizes of materials carried in stock, as far as possible, including bar and sheet metals and other rolled stocks, standard sizes of bolts, studs, nuts, collars, etc. The careful designer will bear in mind that the size of inventories depends in no small degree on his own labor and that he is to a great extent responsible for the carrying of special sizes and odd stocks of materials. He should also keep in touch with the purchasing department and learn the relative market cost of the materials he proposes to use, in order to effect economies in production. All deviations from commercial sizes of materials and from regular shop practice, which involve special or additional operations, mean the carrying of greater or lesser stocks of these odd-shaped parts for the filling of future orders, either for supply parts or for complete apparatus.

A reasonable degree of familiarity with machine practices and labor operations in the shop is desirable in order that these processes may receive proper consideration before the new design is turned over to the draftsman or sent to the pattern department or machine floor. The tool maker, pattern foreman, foundry and machine-shop foremen are all interested parties in the work of designing. They constitute a valuable aid to the engineer. Constant consultation with these men and constant investigation of shop methods and practices appear essential in order to avoid the work of rebuilding and changing apparatus in the regular manufacturing departments.

Coöperation of Engineer and Shop

It is desirable, also, for the engineer to cultivate the good will of the mechanical forces in the shop. Many shop mechanics possess the genius for improvement and invention and are filled with valuable ideas that are often useful to the engineer. Some measure of the high cost of manufacturing is doubtless due to the design being placed in the hands of the draftsman and shop foreman in too incomplete a form and also to the omission of gathering all the useful facts possible from the shop before the draft is made. All this means waste of time and material and a delay caused by working over the design after it has reached the manufacturing department, with a consequent stoppage to the progress of production.

It is a far more economical procedure to thrash out the majority of these questions as to materials, foundry and shop practice, etc., through investigation and conference in the initial stages of the design and to turn over to the shop a practically perfect working drawing. By following this practice it will often develop that valuable changes can be made either in machine processes or materials. As an example, small parts called for in the design to be made of castings can often be made more cheaply of bar or rod stock on the automatics or semiautomatics or stamped and formed out of sheet in a punch press or made as drop forgings. It is also possible in many cases so to reduce the amount of surplus stock to be removed as to admit of finishing the surface by grinding instead of on the planer or miller.

An incomplete or faulty design throws upon the shop a burden that does not belong there. It compels the foreman to inspect and analyze each drawing before turning it over to the machine or bench hand, in order to ascertain if it is practicable and profitable to follow out its provisions and requirements without question or alteration. He does this often with the feeling that, if omitted, the workman will discover inconsistencies after the materials have been gathered and the machine tools set up for the work. He is also on record with his manager or superintendent in the matter of living up to his schedules of productive output, which he cannot do if the drawings are not in proper shape for his men to proceed.

An incorrect design may also prove to be responsible for expensive errors in manufacturing. It may involve changes in operations or materials and the building or purchase of special tools that are afterward discovered to be unnecessary. To it, also, may sometimes be directly attributed high labor prices and prohibitive factory costs.

One of the elements that limit the work of the young engineer just graduated from the technical school is the fact that he has had but a comparatively abbreviated experience in the field of technical research and study and practically no experience in the field of invention and

*Prepared for the author's forthcoming book on "Industrial Economics."

†Factory economist, General Electric Co.

design. Unless he exercises proper caution, there is a tendency to develop the habit of depending on the knowledge and experience of others rather than striving earnestly to develop his own inventive genius and power and accumulate valuable knowledge along the lines of designing and engineering work.

Some of these young men who have had a fair degree of preparatory instruction and training lack initiative and do not possess the proper amount of inventive spirit to make them successful in their work. They too often go to the shop foreman and machinist and draw from them the knowledge needed to fabricate a design and, after the labor of putting the shopman's ideas into a preliminary draft is performed, issue instructions to the drafting room and manufacturing floor. This is not designing in the true sense.

The young engineer should seek rather to construct the design as fully as possible, first, in his own mind. He should develop by minute, critical analysis the picture of the apparatus he proposes to build and study it in all its phases relating to patterns, molding, machine labor, materials, etc., before going to the shop to interview the foreman. He will then be prepared to discuss all the important points relating to processes in the construction with a fair degree of intelligence and will not only create a favorable impression of his ability, but will also secure the valuable coöperation of those whose help he needs. He must not lose sight of the fact that he can get more practical knowledge in the shop than he has received from his books; and if he is fortunate enough to have received a thorough mechanical education through direct personal contact with the work of the foundry and machine shop, he is all the better equipped for his profession and is to be congratulated for the advantage he possesses over many of his fellow-engineers.

It is desirable that the company's designs embody distinctive features of originality and avoid, as far as possible, any duplication of essential details covered by the patented designs of competitors. The engineer should aim to have his design distinctive in many important features, embodying not only the elements of new constructive thought, but also the elements of improvement in utility and efficiency.

Copying Is Not Good Designing

Copying the designs of competitors is not, in general, good designing, nor is it indicative of engineering skill. Although the copy may embody sufficient changes to avoid legal complications, it not infrequently involves the use of more material and additional labor operations that increase the factory cost above that of the competing concern. The engineer is required to produce something better than his competitor—a design that will perform the same or additional functions at a lower cost both for labor and material. He must place the company that employs him in the lead in producing new designs and superior product, if he is to render his services of practical economic value to his employer. And to do this he must be a constant student of local factory conditions and of shop practices in general throughout the country.

So much is required of the engineer in these days of unprecedented progress in mechanical science that it is difficult to enumerate and properly classify all the varied qualifications and elements of knowledge which he must possess in order to fully meet the expectations of the bigger corporate industries. The fact that he must study his design from so many different viewpoints in their relation to utility, economy and efficiency makes it all the more certain that his knowledge and training must be well-nigh without limit in the breadth of their scope.

The Art and Practice of Drafting

In our discussion in the present article we have been considering the relation of designing to manufacturing. We must not overlook the work of the drafting department nor view it as separated from that of the engineer and the factory, for the drawing is the medium through which the design is interpreted to the shop. Too much emphasis cannot be laid on the importance of making that interpretation sufficiently clear and complete in detail so that errors in manufacturing will be reduced to a minimum. Nor can he emphasize too strongly the imperative need for the draftsman to have had a thorough instruction in his work and a fair amount of knowledge of shop practices, in order that he may render efficient service to both the engineer and the department foreman.

The draftsman of the present day in frequent cases labors under difficulty. One of his chief handicaps is the character of the instruction that he has received in the drawing school. The schools, in general, have failed in a large measure to keep pace with the trend of modern manufacturing and to recognize the revolution in shop practices within recent years. They do not take into consideration the fact that a majority of the employees in the modern factory are not tradesmen machinists. A large percentage of machine and assembly operations have become specialized until the all-round tradesman mechanic exists in a minority only. The pupil is taught to make drawings technically correct and for the most part sufficiently clear to the foreman and skilled machinist; but for the unskilled workman these drawings are frequently a maze of incompleteness and filled with obscure marks of form and dimension largely unintelligible.

We must have drawings that these partly skilled and specially trained workmen can read; otherwise, the time of the high-salaried foreman or assistant foreman will be taken up chiefly with the work of interpretation, when his energies should be applied to getting out product rapidly at low labor costs. It is possible for one of these workmen to become familiar enough with the methods of an individual draftsman to get along fairly well in reading the prints that come from his hands. If, however, he is transferred to other work and is compelled to use drawings made by another person whose methods are different, it is quite likely he will be laboring under the same disadvantages and difficulties under which he originally labored.

All draftsmen do not work alike in the matter of making drawings explicit for the workmen in the shop. Some make drawings much easier to read than others. There should be a uniformity of system. Every drawing should embody complete information on finishes, clearance, limits, etc., and contain sufficient notes of explanation to enable the machine or bench hand to read the drawing readily and accurately. A large amount of time is wasted in the shop in an effort to read and understand incomplete and ambiguous prints.

The draftsman must remember that his drawings are subjected to severe criticism in the factory when they show imperfections and lack of information. If drawings have to be returned frequently for correction, the work-

man gains a poor opinion of drafting work in general. He develops a sort of contempt for the higher-salaried man's inefficiency and in time loses his cheerful spirit of coöperation.

Coöperation Between Draftsman and Shop

The draftsman needs to know more about factory conditions, tool equipment and shop practices in general. He needs to understand the point of view of the workman in the modern shop, who labors under the present-day system of specialization. He should know that under this system the employee requires much more detail and general information on his blueprints than in former years when the greater percentage of tool operators and bench hands were tradesmen machinists. Many draftsmen are handicapped by the lack of this shop training and personal contact with present shop practices; and it is evident that the young beginner will be far more successful later on, if he takes a course of apprenticeship in the factory before entering the drafting school. He will then understand what a drawing ought to show and will more fully appreciate the value of the information it is intended to convey to the workman.

The drafting room must always recognize the requirements of the shop. There is no getting away from this principle and avoiding serious loss. Sending out incomplete drawings is a poor way to begin manufacturing. Insufficient information on blueprints is a common cause of wasted time and labor in the factory and often responsible for wrong patterns, faulty castings, the scrapping of valuable materals, delays in shipment and other difficulties. A poor drawing is a direct cause of high piece prices, inefficiency of operation, and is expensive from any point of view whatsoever.

Need of Explicit Drawings

If the engineer is not sufficiently explicit in outlining and detailing his design, the draftsman should insist upon more information. The outline and assembly arrangement should be complete and show such views and angles as will enable the workman to proceed intelligently and without delay with his operations. It is hardly necessary to state that the drawing should show views that are useful to the workman and omit those which are of no value. The detail parts on the print should be carefully drawn. There should be no confusion of dotted lines and uninterpreted details which the workman must have translated by his foreman before he can start gathering materials or setting up his machine. Location of details, too, is important. If the workman learns to find these always in the same or nearly the same place, this lessens the amount of time he spends in studying the print.

Uniformity of practice in the making of drawings has more to do with reducing the cost of productive labor in the shop than most managers recognize. Unless the draftsman spends ample time making his drawings lucid in details and with sufficient notes of explanation to render them simple and easy of comprehension by the average lathe hand and assembler who is not an educated tradesman machinist, the loss involved in the factory must of necessity be large. The workman is not at fault if he does not know from an examination of the print what he is required to do. He may put a file or polish finish on the surface of a casting where it needs only to be milled or planed, or he may finish on the lathe or planer surfaces that should be finished on the grinder, but it is not his fault. He has not been furnished with proper instructions on his blueprint, and too much is left for him to guess at or, as an alternative, to bother his foreman with questions which should not be necessary.

In like manner the pattern maker is at a loss to know how much extra material to allow for in making the pattern, for the draftsman often fails to state whether a given surface requires planing or simply surface grinding. It happens as often as otherwise that the pattern maker makes allowance for planing or turning by adding stock to the pattern, and the foundry continues to cast according to pattern. Thus, the useless and costly process of machining goes on until someone discovers the waste and error. Now all this trouble emanated from the engineering and drafting department, where it could easily have been foreseen and prevented and where a vast amount of economy in manufacturing processes and materials could be provided for by the establishment of a proper system of uniformity of practice and harmonious coöperation of all departments concerned.

Neither the designer nor the draftsman can do his best work independently of the other. This is one of the faults of the present system. There is too much tendency to throw responsibility on the other man, and this tendency costs the management a lot of money. The burden of straightening out the difficulties and errors falls finally upon the shop, where it obviously does not belong. We need to change the system if we are to prevent loss and delay in the factory. Sending drawings of new designs and new details into the shop without first ascertaining whether the shop is provided with the necessary tools and facilities to do the work is bad business from any standpoint. The amount of new tools and equipment, if any are required, and their cost should be known, as should also the stocks of materials available.

All these questions of factory equipment should be fully investigated before the print goes out; otherwise, the cost of producing the design or part may show a loss, which is frequently the case where proper consideration to this phase of the subject has not been given.

Inspection of Drawings

And here we come to the subject of inspection of drawings. No drawing should be sent to the shop without first having been properly inspected. The inspector of drawings must necessarily be a broad-gaged man—above the average. He needs to know pretty nearly everything about manufacturing, including the work of the pattern shop, tool-making department and foundry in order to act as censor and criticize the work of both the engineer and the draftsman and correct their mistakes. He needs to be familiar with the conditions and processes of production in each individual department in order to see that the workman gets exactly what he requires in the shape of detail or diagrammatic information. It is important that he secure the coöperation of both the engineer and the draftsman in his labors to this end. He should be able in looking over the designer's sketches and the tracings in the drafting department to make many suggestions that will not only save labor operations and material and cheapen the total cost of production, but which will also improve the detail and render the design more efficient and salable as a finished product. His field is one of unlimited value and assistance from an economic standpoint, both to the factory management and the shop.

The shop has an important part to play in the production of drawings. If errors are discovered, a notice should be sent to the drafting department at once and the correction made before the materials have been put through the several machine processes and expensive alterations or repairs incurred. If drawings received by the foreman are indistinct, imperfect or in any manner unsatisfactory or unavailable for use, they should be returned and duplicates called for. The coöperation of the shop in checking the work of the drafting department is invariably beneficial in its results.

A bulletin of new prints and of changes made on existing prints should be issued daily by the drafting department and supplied to the foremen of the manufacturing departments. The notice of changed prints should give the name of the engineer by whom the change was authorized, with the date affixed; also the character and cause of changes, with reasons for making the alteration. If the change is due to error, the name of the person or department responsible should appear. The notice should also embody any action to be taken by the foreman on finished or partly finished material on hand.

In addition to the regular daily bulletin covering all new prints and changed prints that have been issued during the preceding day it is good practice to attach a "Change" slip to all drawings that have been altered before sending them to the shop. The "Change" slip embodies the features of the daily bulletin and serves to bring more emphatically to the foreman's attention the alterations that have been made in the particular drawing or apparatus in which he is directly interested.

This system not only provides for prompt and complete notification to the foreman of all prints issued, but it also prevents many serious and expensive delays and errors. It renders the foreman without excuse for not being posted on all new issues or modifications as rapidly as they occur.

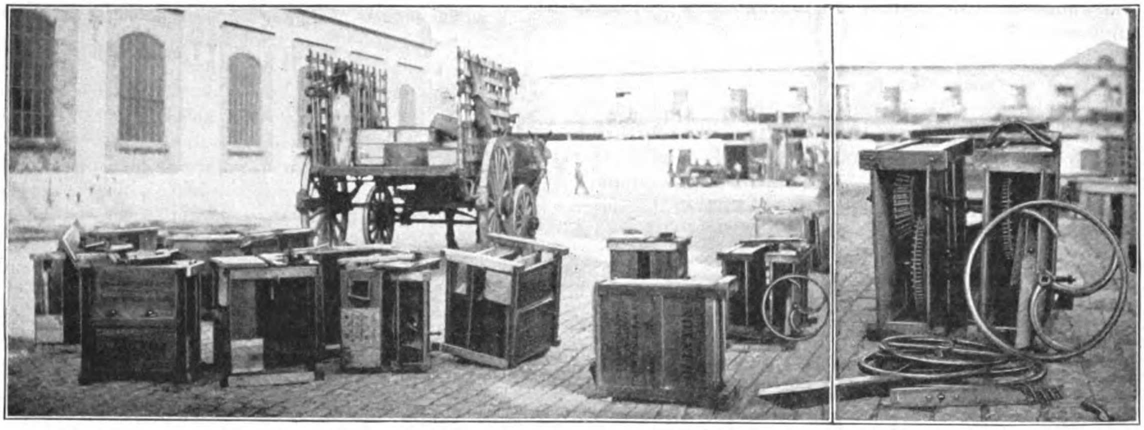
A card record should be made of all new prints issued, embodying the drawing number and name of the apparatus or detail shown. A record of changed prints should also be provided, which may be kept for reference for any arbitrary period desirable. As this record, however, is written upon the original tracings, the retention of the cards beyond the period of their active use becomes unnecessary. Drawing lists and casting lists should also be recorded in a similar manner to that provided for the recording of blueprints. All these records should show the location of the tracings in their proper compartments within the drafting-department storage vaults.

Improper Crating of Machinery

Special Correspondence

Evidence as to the foundation for complaints of poor boxing of shipments to South American ports can be plainly seen in the accompanying illustrations. These photographs were taken by our own representative on the docks at Montevideo, Uruguay.

The flimsy and inadequate boxing is clearly shown in Fig. 1, where a number of cases in a more or less dilapidated condition can be seen in the street. A closer view of the one on the right is seen in Fig. 2, showing the damage sustained. This breakage is not only annoying to the consignee, but it prevents the sale of the machinery, ties up money and disappoints customers until the broken parts can be replaced.



FIGS. 1 AND 2. RESULTS OF IMPROPERLY CRATING MACHINERY FOR EXPORT

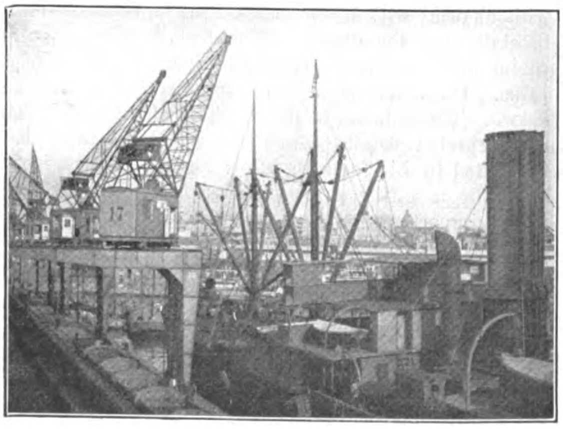


FIG. 3. THE DOCK EQUIPMENT AT MONTEVIDEO, URUGUAY

Lest some assume that these mishaps are due to inadequate methods of handling freight, attention is directed to the gantry and boom cranes with which the dock is supplied.

Making Shells with Regular Shop Equipment

By Fred H. Colvin

SYNOPSIS—Utilizing the standard shop equipment of engine lathes, turret lathes and automatics and securing rapid production with them, building all necessary machines and tools for less than the value of the scrap metal secured in machining and earning a good profit constitute a somewhat unusual story. Only high-grade mechanical ability, coupled with experience and good commonsense, makes such an achievement possible.

The first interesting feature of the methods to be illustrated is the fact that the contract has been filled by utilizing old equipment of an average shop for nearly all operations. All special tools, fixtures and in one or two cases special machines have been made for less than the value of the scrap or waste metal machined from the shells, and a good, fat profit has been made besides. This policy had the double advantage of avoiding the payment of war prices for new machinery and of wearing out the old equipment, so that new can be purchased when prices get back to normal.

The way in which old machines have been utilized to get good production from them by means of ingenious devices, the introduction of new and different ways of handling the work and the careful calculations as to the value of scrap metal are all of peculiar interest. These methods are of particular value to small shops that can be utilized for shell making, if necessary. The shells in question are 3.3-in. British shrapnel made from forged blanks. The first operation is to cut in the open end of the shell a notch that is used in driving the shell during subsequent operations. This work is done in an ordinary punch press, something as shown in Fig. 1, the shell being supported in a holder C under the punch B and located by the rod D. In this way a uniform distance is secured between the bottom of the forging and the punch slot.

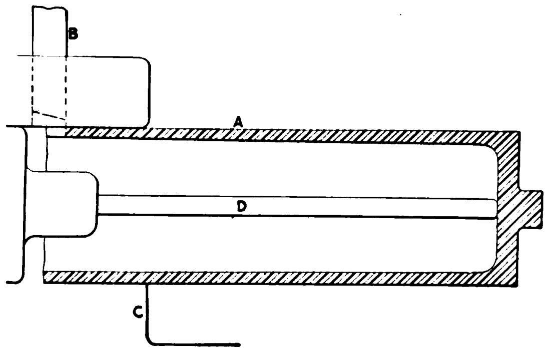

FIG. 1. PUNCHING DRIVING SLOT: OPERATION 1

Machine Used—Any punch press.
Fixtures—Length stop and holder.
Gages—Length—First inspection.
Production—1 man, 1,000 in 6 hr.

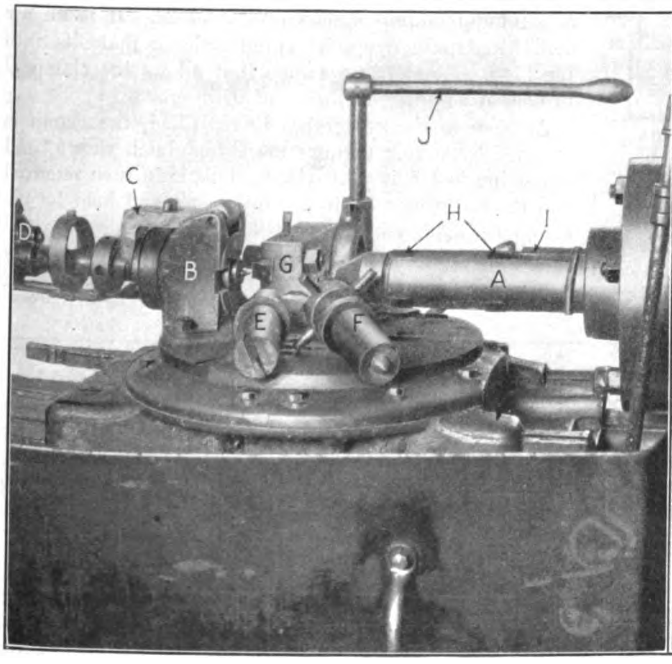

FIG. 2. CENTERING SHELLS: OPERATION 3

Machine Used—Old Jones & Lamson turret.
Fixtures—Aid drill, facing cutter, center, center holder, facing tool block, expanding mandrel.
Gages—Flat steel templet.
Production Time—4½ min.

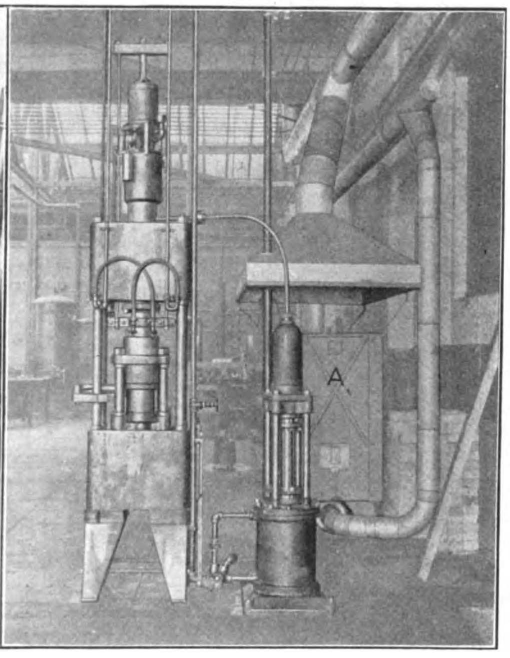

FIG. 5. CLOSING IN NOSE: OPERATION 7

Machine—Home-made hydropneumatic press and heating furnaces.
Fixtures—Dies and tongs.
Gages—Templets.
Production—2 men. 1,400 in 12 hr.

Occasionally a shell is too long to be handled on the driving mandrel, and in such cases the surplus metal is punched off by simply rotating the shell under the punch for a complete turn. Then the driving slot is punched in the usual manner and is ready for machining.

bar centering itself in the forged cavity. Soda water is fed in through the center of the bar itself, this operation requiring 3 min.

An old Jones & Lamson turret has been utilized for operation 3, and it also performs the three suboperations

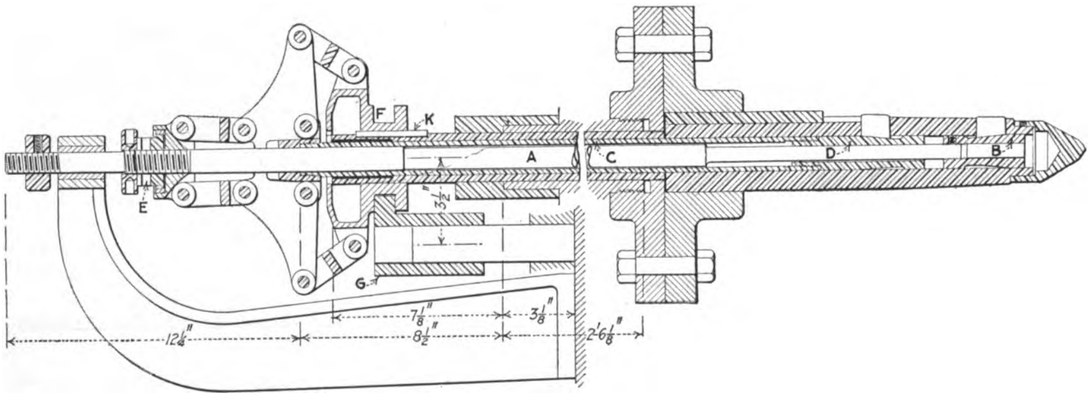

FIG. 3. DETAILS OF EQUALIZING EXPANDING MANDREL FOR TURNING SHELLS

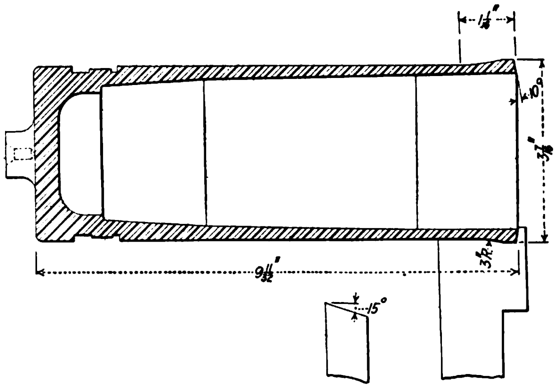

FIG. 4. CUTTING OFF AND FORMING OPEN END: OPERATION 6

Machine Used—Cleveland automatic.
Fixtures—Forming tools.
Gages—Templets of form shown.
Production—9.5 per hr.

of facing the center projection, centering and counterboring, and facing the back end of the shell. The turret is not revolved during these operations, but is locked in a fixed position on the bed.

Fig. 2 shows the driving mandrel *A* with the centering jaws *H* and the driving key *I*. Bolted to the turret is the substantial tool block *B* with the locking device *C*, which is in reality a tool holder. The drill for centering and countersinking is shown in position. It is an air drill fitted with a special spindle sleeve that fits into the block *B* and has a flange that allows the clamp *C* to hold it against the thrust of drilling.

As soon as the center has been drilled, the clamp is removed by simply turning the thumb-latch shown, and the facing tool *E* is substituted. This is in turn removed and the tail center *F* slipped into place and held by the clamp *C*. This center has a screw that allows the tail center to be forced against the work as hard as may seem desirable and is used during the suboperation of

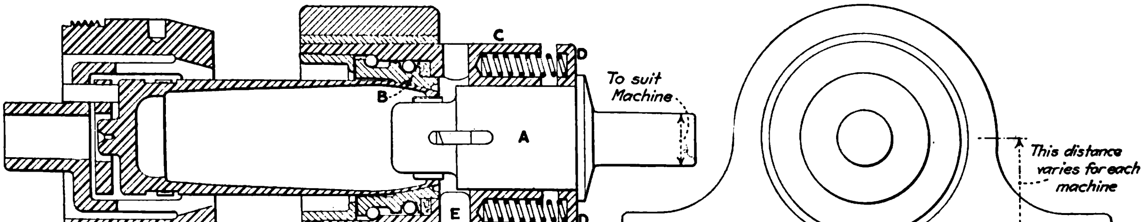

FIG. 6. DETAILS OF FIXTURE FOR TAPPING NOSE: OPERATION 8

Machine Used—Bardons & Oliver turret.
Fixtures—Chuck and steady-rest shown.
Gage—Plug thread gage and nose form.
Production—3 min. each.

The stop *D* was first made rigid; but as it persisted in breaking off under these conditions, it is now loosely mounted in the supporting center and no further difficulty is experienced along this line. A preliminary inspection also takes place during this operation, one man handling 1,000 shells in 6 hr. without difficulty. The second operation bores the powder chamber under the spindle of a heavy Baker drill, the vertical boring

facing off the back end. The side tool that does this facing, shown in the tool block *G*, has a sliding movement across the turret, through a rack and pinion, the latter being operated by the lever *J*. This arrangement gives a good leverage and makes it easy for the operator to face the ends. This operation takes 4½ min.

The fourth operation is the turning of the outside of the shell nearly its whole length, the turning tool

running up practically to the notch cut for driving. This cut is handled by two tools in an ordinary lathe, so that each travels only half the length of the shell. A cutting speed of 42 ft. per min. is maintained, this operation requiring 7 min.

The shells are held on a special equalizing expanding mandrel during the turning operation, illustrated in Fig. 3. This mandrel holds the shells at two points of their length and equalizes the pressure so as to insure equal bearing and equal driving power. It also centers the shells along their entire length. It is shown attached to almost any type of screw machine or other lathe, the headstock being omitted and only the faceplate and end of the headstock shown, the rest being unnecessary.

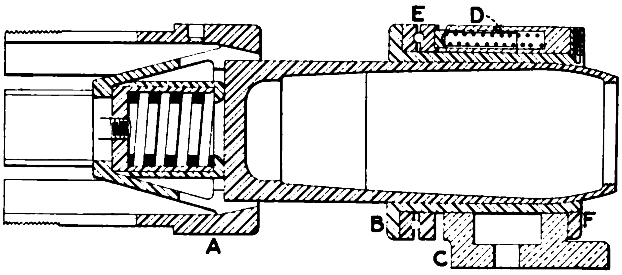

FIG. 7. SCRAPING INSIDE OF NOSE: OPERATION 9
Machines Used—Any suitable turret or engine lathe.
Fixtures—Cross slide and form tool.
Gage—Templet or contour gage.
Production—2 min. each.

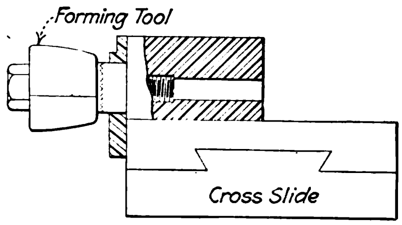

FIG. 8. FORM TOOL USED IN OPERATION 9

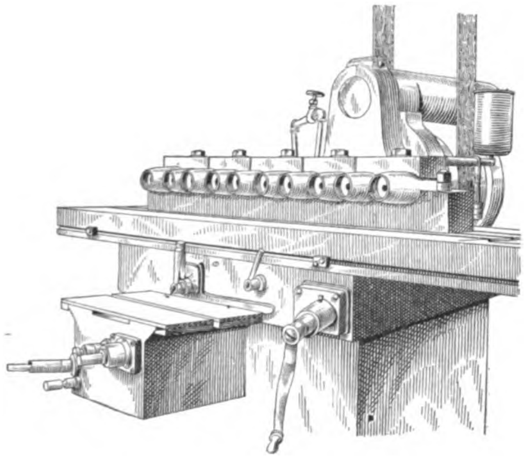

FIG. 10 CUTTING OFF ENDS: OPERATION 12
Machine used—No. 4 Cincinnati miller.
Fixture—Holder for shells.
Gages—Templets.
Production—2 men, 1,400 in 22 hr.

The mandrel consists primarily of the inner rod *A* carrying the wedge *B*, which is turned taper as shown, and the tube *C* with its wedge *D*. Both *C* and *D* operate separate sets of jaws, three in number in each case; and as will be noticed, the inclines are in opposite directions.

The spools *E* and *F* run free, the latter being feather-keyed to the lathe spindle at *K* and revolving with it, but free to move endwise both on the key and with the spool *G*. The chucking lever controls the movement by means of the sliding spool *G*. When this is moved, it pulls back the rod *A* and pushes forward the tube *C*, or vice versa, by means of the toggle levers shown. This movement forces the jaws up the incline and tightens the shell on the mandrel. Should one set of jaws take hold before the other, they act as the stationary member and the other cone forces out the second set of jaws until all bear equally. This is a particularly interesting device that can be adapted for many other uses.

Next comes the roughing out of the band groove, operation 5, done on a Jones & Lamson turret, which also chamfers the corners, the production time being 2½ min. This operation requires no illustration.

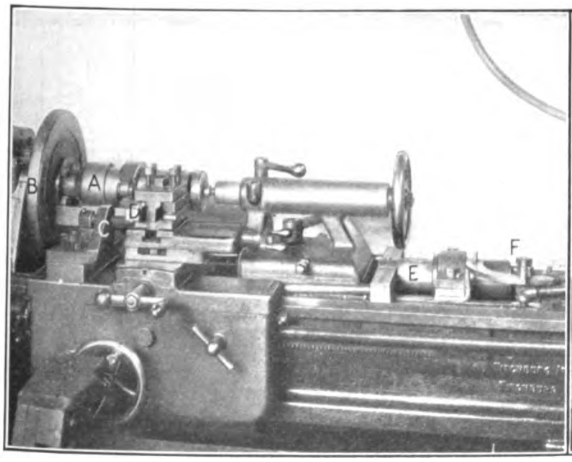

FIG. 9. CUTTING THE WAVES: OPERATION 10
Machine Used—Old Fitchburg lathe.
Fixtures—Cam, tool block, air spring.
Gage—Usual templet.
Production—3 boys, 1,400 in 10 hr.

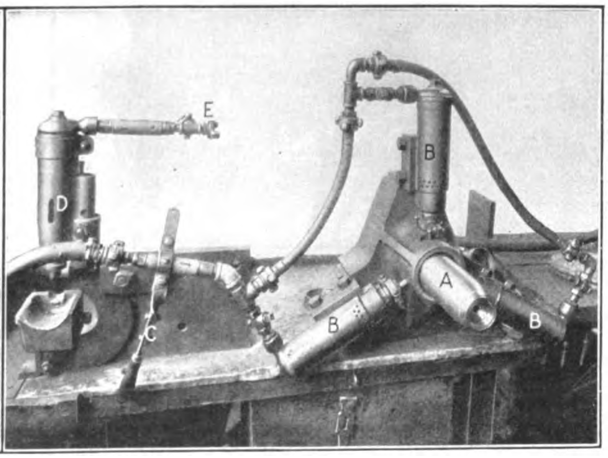

FIG. 11. VENTING WAVE GROOVES: OPERATION 13
Machine Used—Specially arranged air hammers.
Fixtures—None.
Gages—None.
Production—Man and boy, 1,400 in 12 hr.

The ends are cut off and formed for closing in, in the sixth operation. This is done on Cleveland automatics, which happen to be available. Considerable experimenting developed the proper shape of nose to be closed into the desired shape for boring and tapping. The dimensions are shown in Fig. 4, where it will be observed that the open end of the shell is beveled back 10 deg. After being closed, this bevel is turned in and simply requires a little trimming to fit the fuse or adapter.

The closing in of the nose is done on the hydro-pneumatic press, Fig. 5. This illustration also shows

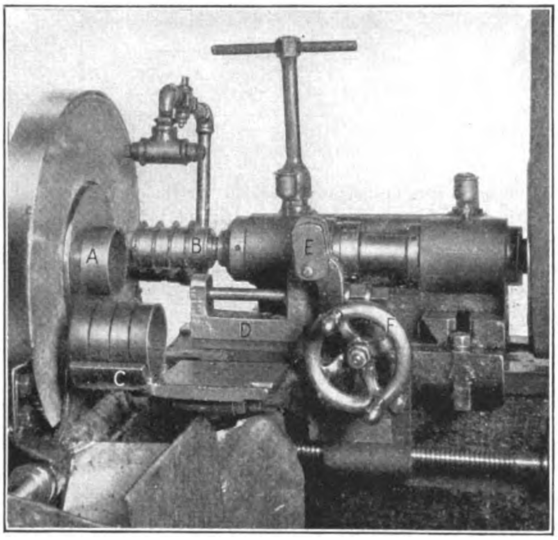

FIG. 12. CUTTING OFF BANDS

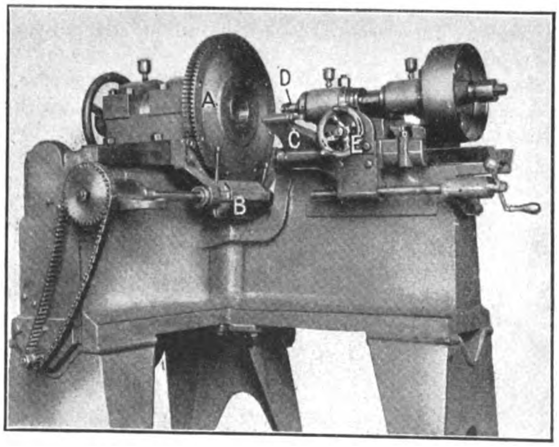

FIG. 14. FORMING THE BANDS: OPERATION 15

Machine Used—Special rotary miller.
Fixtures—Formed cutters.
Gages—Templets.
Production—3 men, 1,400 in 22 hr.

the heating furnaces, which are very conveniently placed. This press has a 12-in. air cylinder with a possible stroke of 12 in. The hydraulic ram is 3 in. with a 12-in. stroke. A 7-in. stroke is sufficient to close the shell nose. The form die comes to a positive stop on the base which clamps the shell. This secures a uniform nosing and eliminates the necessity of turning afterward. Two men handle 1,400 shells, the daily output, in 12 hr. The diaphragms are slipped inside before closing the nose.

The nose is bored and tapped in a Bardons & Oliver turret, equipped with special holding chucks and steady-rests. The boring and facing tool is shown at *A*, Fig. 6, the nose of the shell resting in a revolving support. This sleeve *B* forms the inner race of the double ball bearing and takes care of both the radial and the end

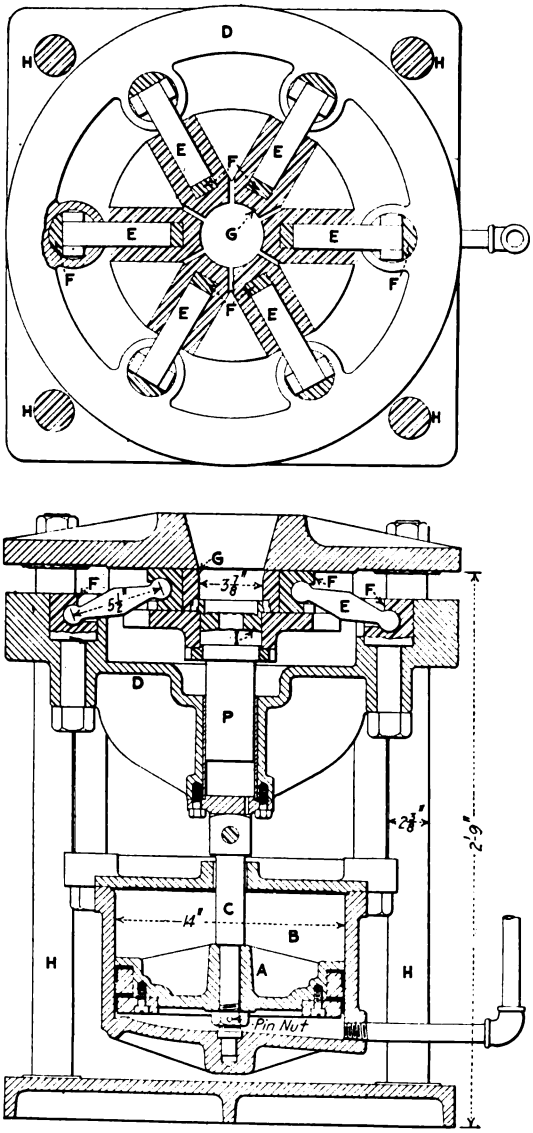

FIG. 13. PNEUMATIC COPPER-BANDING MACHINE: OPERATION 14

Machine Used—Special 30-ton press.
Fixtures—None.
Gages—None.
Production—Man and boy, 1,400 in 12 hr.

thrust, while the felt washer keeps out dirt and chips. It will also be noticed that the outer case *C* projects so as to act as a guide for the boring and facing tool.

The tool *A* is provided with a shoulder that makes contact with the collar *D* and compresses the spring as the tools feed into the shell. The opening *E* provides escape for chips. This guiding the tool with relation

to the shell insures the hole being concentric with the outside, which is quite an important point in inspection.

The tapping is done in the same fixture and at the same setting. This complete operation takes 3 min.

After the boring and tapping of the nose the inside of the shell just beyond the thread is scraped out with a round-formed cutter, Fig. 8. This is a circular form- is mounted in the cast-iron block *C*. The spring plunger *D* regulates the pressure on the thrust bearing *E* and also prevents the front race from turning. The threaded collar *F* holds the other end of the quill in position.

The next, or ninth, operation is to grind the shell all over, a very heavy wheel saddle weighing 400 lb. being employed for this purpose. A formed wheel is

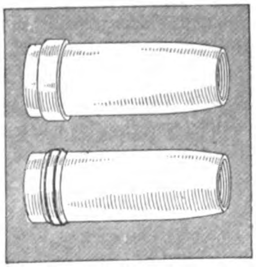

FIG. 15-A. OP. 15. TURN BANDS

ing cutter of the regular type, held from turning by the serration shown at the end, where it bears against the tool rest. The cutter is mounted on a Jones & Lamson cross-slide, the shell itself being held in the draw-in chuck and the special bearing, Fig. 7. The contracting sleeve *A* clamps the jaws on the back end of the shell, the front end being supported by the steel quill *B*, which used for shaping the nose of the shell, the straight part being ground by a plain-faced wheel 6 in. wide. The grinding allowance is 0.015 in., and eight men—four men to each shift—grind 1,400 shells in 22 hr.

Waving in the groove already roughed out in operation 5 is done in an old lathe, as indicated in Fig. 9. The nose of the shell is supported in a sort of bell chuck

A and held in position by the strap shown in front of it. The cam is on the faceplate *B*, while *C* is a stop to locate the position of the waved tool *D*, which is held in the compound rest set parallel with the lathe ways.

The unusual part of the arrangement is the use of the air cylinder *E* in place of the usual spring or weight. A spring was first tried, but the inconvenience of getting it out of the way when it was not needed led to the adoption of the pneumatic cylinder.

When the spring action is necessary, the cock *F*, swung on the quadrant between the two pins shown, admits air to the cylinder and forces the roller on the lathe carriage against the cam on the faceplate. When the spring is not needed and it is desired to move the tailstock or the carriage, the cock *F* is swung into the other position, which shuts off the air and opens an escape vent from the cylinder. This arrangement has worked out much more satisfactorily than the spring formerly used. Three boys handle 1,400 shells in 10 hr., or about 45 shells per hour for each lathe.

The projection on the closed end of the shell is next milled off, as shown in Fig. 10. The fixture is a simple one that goes on a No. 4 Cincinnati knee-type miller and holds ten shells at one setting. It will be noticed that these shells are held by five separate straps, these being used so that as soon as a section has passed the milling cutter the milled shells can be removed and others put in their places. In this way almost continuous milling can be done, two men handling the 1,400 shells in 22 hr.

The device for cutting the air grooves across the waves is illustrated in Fig. 11. The shell *A* is acted on by the three air hammers *BBB*, the piping connections being shown. Needless to say, these vent or nick the waves very rapidly, as fast as a man can handle the shells. The handle *C* controls the air to the hammers.

At *D* are a single air hammer and a simple holder for the shells. They are solely for use in case the triple arrangement gets out of order from any cause. Should this occur, all that is necessary is to connect the air hose at *E* and go ahead.

The banding is handled in a somewhat different manner than usual, both the machine for cutting off the bands and the one for pressing them into place being built especially for this job. The cutting-off machine is shown in Fig. 12, with a tube in place at *A* and with the four milling saws *B* properly spaced for the width of band desired. The backrest *C* is shown thrown down and holding the four rings, which have just been cut off. It effectually supports the rings being cut against the thrust of the milling saws; and when the cut is completed, lifting the latch *E* releases the rest and allows the four rings to be easily removed. This backrest is located in position by the surface *D*. The cutters are fed into the work by the handwheel *F*. These four saws are but $\frac{1}{32}$ in. thick, so that the waste of copper is very slight. The machine cuts 180 bands per hour and while this may not be as fast as in some other cases, the saving in copper probably more than compensates for any loss of time. Furthermore they are very true to length.

The banding machine, Fig. 13, is operated by air at the regular shop pressure of 100 lb. to the square inch. This acts on the 14-in. piston *A* in the cylinder *B*, giving a total pressure of 30 tons to the square inch. By means of the toggle *F*, pressure is transmitted through the rod *C* to the head *D*, which slides on the four round guides *H* and also the central plunger *P*. The toggles *E*, working in the thrust blocks *F*, force the six steel jaws *G* against the copper band, compressing it into the band groove from all sides. This press is very quick acting, and five or six strokes are usually employed, turning the shell slightly each time, as is usual. One man and a boy band 1,400 shells in 12 hr. The main dimensions of the press are given in Fig. 13.

Instead of turning the bands as usual, this shop found it advisable to build two special millers, Fig. 14. These are simple affairs, as can be seen, consisting of a work-holding spindle carrying a wormwheel *A* and being driven by the worm *B*. The shell, with the band in place, is slipped into the hollow spindle and held by a draw-in chuck operated by the wheel at the end. The shell is located by the swinging stop *C*, which drops out of the way as soon as the shell is in position. The milling cutter *D*, which is formed to give the shape of the copper band, is driven by an independent belt and can be moved either longitudinally for location or fed into the work by the crossfeed wheel *E*. This method of finishing the bands has been found very satisfactory, three men and two machines finishing 1,400 bands in 22 hr.

Altogether this makes a very interesting plant, and the output of 1,400 shells per day, with an average of 28 min. each, reflects credit on the mechanical ability of those in charge.

Third Annual Convention of Drop Forgers

The third annual convention of the American Drop Forgers Association was held at the Hotel Adelphia in Philadelphia, Penn., on June 9 and 10. One hundred and fifty members and guests were present and displayed an interest in the proceedings which forecasts a bright future for this three-year-old association.

The address of welcome was delivered Friday morning by Howard B. French, president of the Philadelphia Board of Trade, followed by an address by E. J. Cattell, city statistician. Twenty-five years of Mr. Cattell's life were spent studying industrial conditions in the countries now at war, and from conclusions based on his knowledge of conditions and resources abroad he made the following statements of interest to manufacturers in this country: "The war will end within one year, leaving Europe far from exhausted in the matter of financial resources. Countries abroad have been 100 years in making and saving money and are now in the position of a man who must get along with 13 motor cars instead of his usual 15. The enforced economies have resulted in a new power of self-denial of unnecessaries which will offset the unusual expenditures." Mr. Cattell predicts a great volume of business for American manufacturers in helping to rebuild Europe.

An opening address was made by the president of the association, F. A. Ingalls, in which he dwelt upon the importance of the drop-forging industry and told of the vital effect of this art upon the automobile industry to the mutual upbuilding of both. He referred to the necessity of a free interchange of information and ideas for the full development of the drop-forging art and urged the furthering of association membership to this end.

At the forenoon session a paper entitled "Selection of Proper Machines for Making Forgings" was read by R. T. Herdegen, of the Dominion Stamping and Forging Co. The author pointed out the necessity of the selection of machine units suited to the particular job in question for the purpose of securing minimum costs. Three types of machines were considered—board drops, steam drops and upsetting machines—and examples were given, showing a minimum-cost job for each type, the figures including die cost, material, direct labor and the complete overhead charges.

"A Floating Type Head for Board Hammers," by Howard Terhune, of the Chambersburg Engineering Co., presented a description of the floating head of the Chambersburg board drop and told of the conditions leading up to its adoption. Mr. Terhune also sketched the historical development of the board drop from the first hammer at Colt's armory to the present-day hammer.

"Multiple Mechanical Die Sinking," a paper by Jules Dierckx, of the Keller Mechanical Engraving Co., was read by S. A. Keller. It pointed out the fundamental advantages of the mechanical sinking of dies as done on the Keller machine. The flexibility of control of output under varying labor conditions and the separation of the functions connected with die sinking requiring skill not heretofore combined in one individual, were outlined as important advantages aside from the reduced cost of dies thus made.

At the afternoon session "The Forging of Automobile Front Axles" was read by J. F. Zwicker, of the Willys-Overland Co. Mr. Zwicker gave an interesting and detailed description of his method of producing the Elliott type I-beam section front axle as used in the Overland car. He also produced some examples of work done on the upsetting machine with plain and sliding dies at a minimum cost. The discussion of this paper brought out the feasibility of thin-forging alloy-steel flanges, according to Mr. Zwicker's experience this being possible on a 7½-in. diameter flange, $\frac{5}{16}$ in. thick, gathered from 1½ stock, this case being the wheel flange on a rear axle.

"The Heat-Treatment of Drop Forgings," by W. C. Peterson, of the Packard Motor Car Co., presented a series of personal investigations on various methods of heat-treatment, applicable to drop-forged products and particularly to automobile forgings. Mr. Peterson told of tests on the structure of the same forgings, made under a various number of blows, and pointed out the advantage in granular structure and tensile strength secured by a large number of blows.

In " Modern Methods in Making Six-Throw Cranks," A. A. Motherwell, of the Buick Motor Car Co., described the method and dies used in producing the six-throw crank for the Buick car and also his experiences in developing these methods. Mr. Motherwell outlined his mode of increasing production by the use of two furnaces and two forging gangs at one hammer, whereby he is able to get 600 six-throw cranks from one hammer in 22 hr.

"The Manufacture of Drop-Forging Steel," by H. N. Taylor, of N. & G. Taylor Co., dealt with the method of rolling billets into bars with a view to eliminating pipes and seams, as applied to the carbon-steel forging stock produced by this company.

The association banquet was held at 6:30 p.m., followed by a theater party and buffet supper.

At the session of Saturday morning, June 10, "Sand Blasting of Forgings" was read by W. C. Lytle, of the Pangborn Corporation. The author described the various methods of cleaning forgings by pickling, tumbling and various types of sand-blast apparatus, including the barrel type, cabinet type, hose type and table type. He classified the purposes of sand blasting as to the removal of scale before and after heat-treating and to secure a matte surface for painting. During the discussion the purpose of sand blast for uncovering defects was discussed. The difficulty in cleaning alloy-steel forgings by the sand-blast process was said to be overcome by the use of No. 5 round chilled-steel shot. Mr. Motherwell told of the installation of wire brushes at his hammers at the Buick plant for the purpose of uncovering defects prior to completing the forging.

In his paper, "Sources of Heat for Forging Furnaces," A. A. Holbeck, of the Bonnot Co., described the operation of a powdered-coal plant adapted for small furnaces, using the central distributing system and distributing the coal by means of air in galvanized pipes. As small a fuel consumption as 10 lb. per hour per furnace is possible with this system. The temperature of combustion is 3,400 deg., and the final cost results with coal at $3 per ton are equivalent to fuel oil at 1½c. per gallon.

"The Hammer-Hour Overhead System," by A. A. Motherwell, Buick Motor Car Co., described the system of overhead distribution to individual machines and groups of machines which has been worked out at the Buick plant. Each machine must make a showing for itself, and the burden is spread over each piece, a loss or gain in burden and production being reported daily on a form provided for that purpose. The hourly burden rate for hammers varies from $1.50 for a small machine to $17 per hour for a 12,000-lb. hammer. Mr. Motherwell also pointed out how savings can be made by specializing and studying concrete problems, a saving of $13,000 having been made in one year simply by studying and reducing the flash and gate-ends on connecting-rods.

"Recent Developments in the Use of Upsetters," by F. O. Andrews, of Acme Machinery Co., illustrated the possibilities in the use of these machines by showing a forged spiral beveled-gear blank in which the teeth had been produced in a total of three operations on an upsetter. The ring was produced from flat stock by two operations aside from those described.

"The Practical Use of the Pyrometer," by C. R. Cary, of Leeds & Northrup Co., pointed out the errors to be guarded against in the practical use of pyrometers and told of temperature differences ranging from 25 to 100 deg. F. at different portions of the same furnace. The author emphasized the necessity of placing the fire end so that it will correctly measure the work that it is heating.

The following officers were elected for 1916: President, R. T. Herdegen; vice-president, T. W. Sieman; secretary and treasurer, E. B. Horne.

During the executive session the following resolution presented by President Ingalls was passed unanimously:

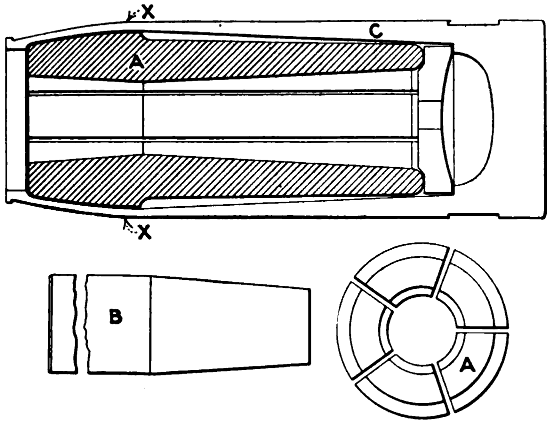
Be It Resolved, That we, the members of the American Drop Forgers Association, hold ourselves in constant readiness at all times to serve this country with our trade, knowledge, our equipment and our men for any necessary military defensive action that our Government may require from us. We also declare that we are in favor of all unselfish efforts toward such military and industrial preparedness as will serve to provide an adequate safeguard against attack by any enemy.

Expander for Reclaiming Undersize Shrapnel

By H. Watts

The device shown is an expander used in shrapnel making for increasing the diameter of rejected shells where the diameter of the nose has been ground too small. A concern making shrapnel had thousands rejected on account of the nose diameter being under minimum size. This device was used and all the rejected shells expanded and reclaimed. This device has been in service every day for the past six months. It can be used under a press or by a man with a 10-lb. sledge hammer.

The sectional drawing shows the expander *A* in position in the shell *C* ready to have the taper pin *B* inserted. The expander is made from 90- to 100-point carbon tool steel,



EXPANDER FOR UNDERSIZE SHRAPNEL

hardened, and tempered to a brown color. After turning, it is cut into five sections with a $\frac{1}{8}$-in. wide saw in the miller. This permits the sections to pass in and out freely at the small opening where the fuse socket screws in. The bottom of the expander rests on the top of the disk. The taper in the expander is $1\frac{5}{16}$ in. per ft. and on the pin 2 in. per ft. This steep taper was given so that the pin would not stick in the expander and cause loss of time. It takes about 1 min. 20 sec. to expand a shell. The expanding takes place at *X*. Heavy grease should be put on the tapers in use.

Fuels for the Oil Engines

By John F. Wentworth

When Diesel began his work, he was not content with the idea of using liquid fuel, but proposed to use pulverized coal as well. This proved inadvisable because of the ash, which must have a bad effect upon the cylinder even if a valve could be made that would handle the coal. There seems to be no good reason, however, why all liquid fuels cannot be used in the oil engine.

One thing for consideration is the ignition points of the different fuels. There is good reason to believe that this point is practically constant for all fuels. If this be true, the only limitation to the fuel for use in the oil engine is that placed by high viscosity, and this seems to be overcome when the fuel is heated and fed through a valve that does not require a water jacket.

The first reason for believing that all fuels have practically a constant point of ignition is in the fact that the chemical composition of all hydrocarbons is practically constant. The carbon content varies from 80 to 90 per cent. and the hydrogen content from 8 to 15 per cent. Even the solid residues from fuel of an asphaltum base come within this range. The only reason for questioning this statement of ignition point would lie in the fact that these fuels have the carbon and hydrogen united in different series of hydrocarbons.

By ignition point is meant the point which, if the fuel be brought in contact with air of the same temperature, ignition will take place spontaneously. This should not be confused with the flashpoint, which is simply the point at which a vapor is given off that readily forms an explosive mixture.

The best practical proof of this common ignition point lies in the fact that the oil engine has shown that heavy fuels will ignite at around 1,000 deg. F., and the condition at which a vapor engine will continue to run even if the ignition means be discontinued is clearly over 800 deg. This can be determined by a calculation of the amount and temperature of the products of combustion remaining at the end of the discharge stroke and by an approximation of the temperature of the charge when it has been drawn into the cylinder over the hot head.

A Universal Fuel Valve

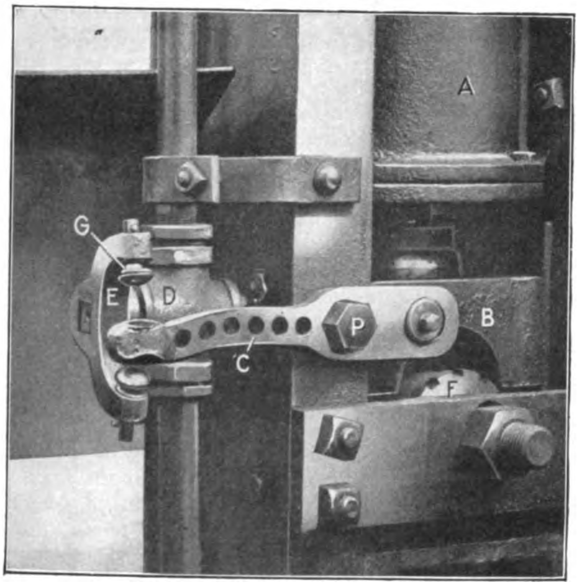
If the ignition points of all hydrocarbons be practically constant, the problem narrows to one of physical properties. The fuel must be reduced to a liquid condition by the addition of heat, and the fuel valve must be so designed that it will not depend upon the size of the passage for producing a perfect spray; for if it does, a valve that will use a heavy fuel with good results will deliver a lighter fuel into the cylinder in the form of a slug of oil. On the other hand, a differently proportioned valve will use the lighter fuel with good results and fail on the heavy fuel. Consequently the use of all grades of fuels in the same engine simply depends upon the design of a fuel valve in which the fuel is positively presented to a current of fast-moving air. It should be easily possible to design such a universal fuel valve, the point being, is it worth while to produce such a fuel-feeding arrangement?

In the description of a marine oil engine of the Werkspoor type, the statement was made that heavy fuel can be used, but the difference in cost between this oil and a lighter oil is so slight that there is but little use in taking the trouble with the heavier fuel. This is a confession of unreliability with the heavy oil. In engines of large power, which are coming to the front rapidly, 0.10 of a cent a gallon will amply repay the trouble of designing a positive and reliable means for using the lowest grades of fuel. Those engines that can use the poorer grades of fuel with absolute reliability will drive out the engines using the lighter and more expensive fuels. In fact the chief advantage of the heavy-oil engine lies in the hope of using all grades of liquid fuels. Purchasers of oil engines should look into this point very carefully before buying. It may be that owing to transportation costs the better oil will be as cheap as the poorer oils in some localities, but this is a condition that will be overcome to a degree at least as soon as the engine is produced which shows a broad market for the lower grades of oil.—*Power.*

Letters from Practical Men

Automatic Valve for Flue Swager

Herewith is shown a simple arrangement of valve control for a flue swager, which is used for swaging the ends of locomotive superheater flues after new ends have been welded on. As originally designed it was necessary for two operators to step on a foot treadle for every stroke of the piston. With the new arrangement the air valve is



AUTOMATIC VALVE FOR FLUE SWAGER

held open by a foot treadle and the machine operates at about 300 strokes per minute.

The illustration shows the back side of the machine. *A* is a 6x12-in. single-acting air cylinder; *B* is the upper swage block fastened on the piston rod. Each of the swage blocks is about 8 in. square by 4 in. thick. The two swage blocks are forced apart by four stiff spiral (or coil) springs, one on each corner of the block. *D* is a $1\frac{1}{2}$-in. threeway cock that is operated from the swage block *B* by the valve lever *C* pivoted at *P*. The lever *C* acts on the valve *D* through the fork *E*, which is provided with bottom head pins and springs, shown at *G*, to cushion the blows from the lever *C*. *F* is the mandrel for centering the flues. This device has been in operation for $2\frac{1}{2}$ years without giving trouble.

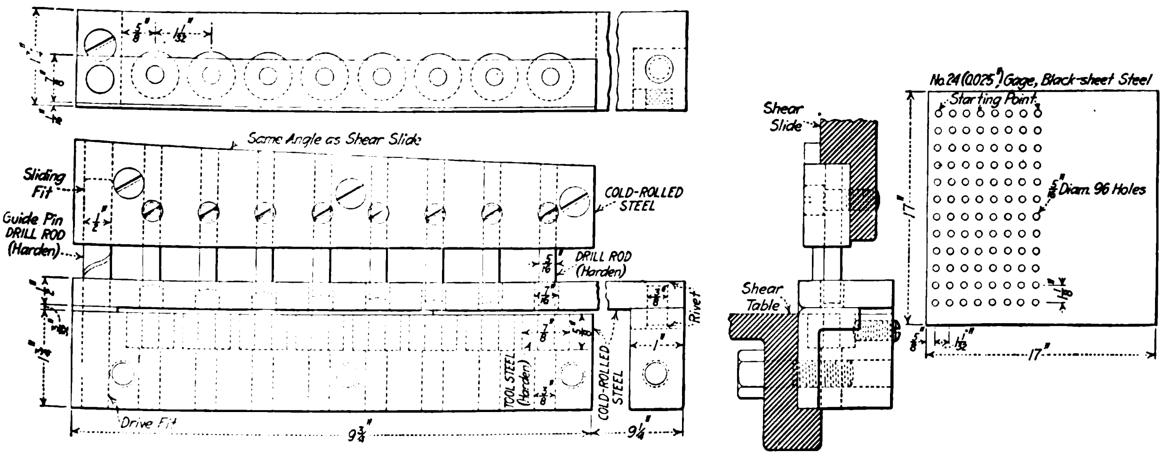
Minneapolis, Minn. WILLIAM SEELERT.

Converting a Squaring Shear into a Gang Punch Press

The illustration, Fig. 1, shows a gang punch used successfully in a common squaring shear. A lot of 4,000 pieces of sheet metal, 17x17 in. by 0.025 in. thick, had to be punched with ninety-six $\frac{5}{16}$-in. holes, as shown in Fig. 2. There was no power press large enough for this job, so a few pieces were first made by using a templet and punching one hole at a time in a hand punch. On account of the large number of holes in each piece this was slow work, so I tried another solution of the problem.

The upper and the lower knife and the front and rear gages were removed from a 32-in. squaring shear. The tools shown in Fig. 1 were made to fit in the same position as the knives, and the same screw holes were used for attaching them. The spacing of the holes between each row on the work was done by placing a piece of $\frac{1}{2}$x$\frac{1}{2}$-in. cold-rolled steel 17 in. long in the screw slot on the table. This piece had graduations $1\frac{1}{8}$ in. apart, and the work was simply moved forward one mark after each stroke of the punch.

The die block is a piece of cold-rolled steel $1\frac{3}{4}$x$1\frac{3}{4}$x$9\frac{3}{4}$ in., with inserted tool-steel dies that are held by $\frac{3}{8}$-in. setscrews. The stripper plate is also made of cold-rolled steel $\frac{1}{2}$x$1\frac{3}{4}$x$18\frac{3}{4}$ in. and is fastened to the die



FIGS. 1 AND 2. CENTERING A SQUARING SHEAR INTO A GANG PUNCH PRESS

block at one end by a fillister-head screw. The other end is attached to the table of the shear. The punch holder is made of $\frac{7}{8}$x$1\frac{7}{8}$x$9\frac{3}{4}$-in. cold-rolled steel, with the upper side planed to the same angle as the shear slide. The punches are made of $\frac{5}{16}$-in. drill rod $2\frac{9}{16}$ in. long. The lower ends of the punches are ground to an angle, to make them shear through the metal more easily.

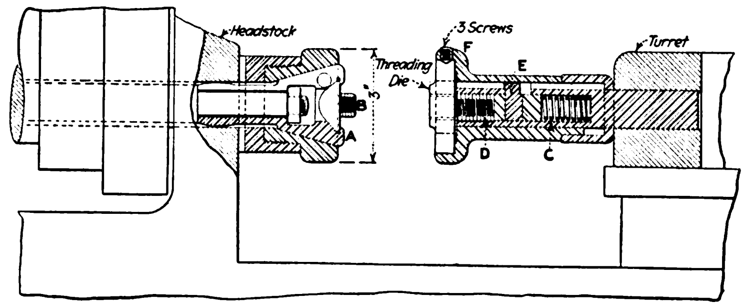
If the punches are oiled frequently, it requires little effort to force them through the work. We also punched $\frac{1}{32}$-in. sheet metal with equal success. G. B. OLSON.

Bridgeport, Conn.

Thread-Chasing Fixture for Small Parts

A quick and efficient method of chasing fine threads that lead up to a shouldered part is here shown as applied to a hand screw machine.

A three-jawed draw-in chuck A is made to fit the machine used for centering and driving the part B to be threaded. A die holder or sleeve of sufficient length to insure the necessary bearing and allow for the amount of travel required for clearance while placing the work in the chuck and threading it is made to slide on a post secured in the turret head. The post should be of the same diameter as the hole in the turret head and should be bored to receive a spring C, which keeps the locking bolt D pressed forward.



THREAD-CHASING FIXTURE FOR SMALL PARTS

The bolt is projected through an elongated hole E in the post and is a sliding fit in the slot or keyway cut the entire length of the die holder to prevent it from turning while it is being pushed forward to the work.

The end of the sleeve F is turned down to receive a shell that fits the post and allows clearance for the locking bolt when the die is threaded up against the shoulder of the work, allowing the die to revolve with the work and preventing the sleeve from coming off the post.

The end of the sleeve is cut on a spiral, beginning on one side of the keyway and ending at the opposite side. The purpose of the spiral is to form a lock when the power is reversed, caused by the spring in the post pressing the locking bolt against the shoulder on the end of the sleeve, which is in line with the slot, thereby backing the die from the thread.

The die holder is turned down to remove weight and to make a good grip for the hand. The die, which should be ground down on the face to clear the jaws of the chuck, is held in place by three screws. A very slight amount of clearance should be allowed in the holder for a float. The sleeve should be a good sliding fit on the post, to prevent sagging.

In operation the turret head is set so that when the die holder is screwed up against the shoulder of the work the holder will revolve with the work, as the locking bolt must then be out of the slot in the sleeve. The turret is then locked in this position, and the die holder is operated by hand, which makes it more sensitive for catching the thread and producing good work.

Allston, Mass. JOHN J. EYRE.

Camshaft-Grinding Fixture

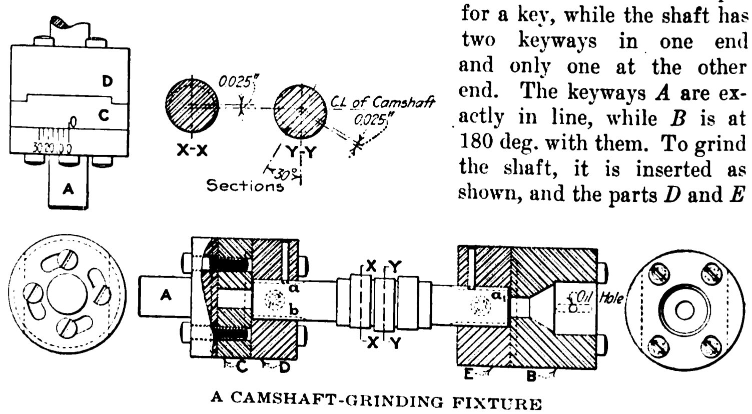
In order to grind shafts with eccentric cams of sections XX and YY, having an eccentricity of 0.025 in., 0.050 in. and 0.075 in., the fixture shown was designed. These cams had to be within 0.001-in. limit, and no trouble was experienced in keeping within that limit with this fixture.

The part A is clamped in the spring collet of a 16-in. engine lathe, while the part B is running on the ground center in the tailstock; C is graduated and fitted to A with a $\frac{1}{8}$-in. register and by four $\frac{1}{4}$-in. screws. A hole runs concentric with the register.

The pieces D and E are fitted to C and B respectively, so that the fixture can be shifted $\frac{1}{8}$ in. out of center and held together by four $\frac{1}{4}$-in. screws. D and E have each a $\frac{3}{4}$-in. reamed hole, while C and B have each a $\frac{3}{8}$-in. reamed hole.

Before setting up a job for grinding, a $\frac{3}{4}$-in. plug with a $\frac{3}{8}$-in. shank is placed in the reamed hole, the parts screwed together and the outside turned concentric with the bearing B and the shank A respectively.

As will be seen, the parts E and D have each a pin for a key, while the shaft has two keyways in one end and only one at the other end. The keyways A are exactly in line, while B is at 180 deg. with them. To grind the shaft, it is inserted as shown, and the parts D and E are clamped with the aid of an indicator to 0.025-in. or whatever eccentricity is required. Having ground the section XX, the shaft is taken out from the part D and



A CAMSHAFT-GRINDING FIXTURE

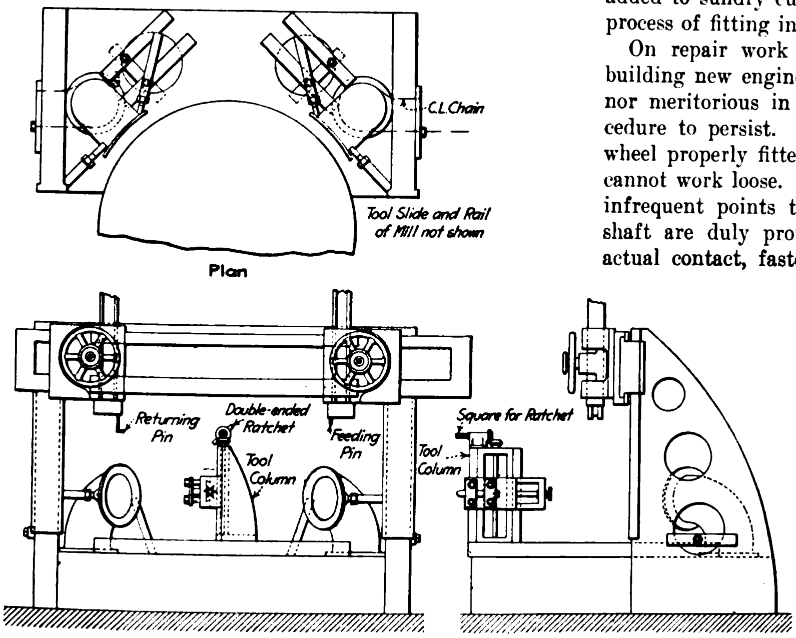
the fixture placed in the keyway *B*. The other end should remain unchanged. After loosening the part *C* and turning it to the required angle, as section *YY*, the other cam can then be ground. A. B. GAMORY.

Detroit, Mich.

Machining 24-In. Elbows

A few months ago at the plant of the Ironton Engine Co. we were making some castings for a blast furnace, among them two 24-in. elbows with 30-in. flanges. They were flat on one face and had a 54-in. radius on the other. Owing to some changes on the pipe line after these castings were finished, this radius had to be changed or new castings made.

Our superintendent suggested that we clamp the castings on the bedplate of our 10-ft. boring mill, fasten to the table an old head that was lying around the shop of the mill and change the radius face of these castings to suit the new condition.



MACHINING 24-IN. ELBOWS

The screw of the head was driven by a pair of bevel gears and a ratchet, which is plainly shown in the sketch. By using a kick pin in each head we were able to get a continuous feed.

These castings, weighing from 1,150 to 1,200 lb., were put on the mill, and one good heavy cut was taken down this face in 10 hr. F. J. HENDERSON.

Ironton, Ohio.

Fitting Flywheel Keys

In spite of modern machine-shop methods and recent advances the matter of fitting and keying a flywheel is in too many instances today an operation of the primitive and muscular type. Why this should be so is a little difficult to understand. Engine shops do such work on a time-limit basis, but by methods that seem to the onlooker archaic. The resources of modern grinding seem not to have penetrated to any depth in the conservative practice of many engine shops.

Shaft and bore are machined and assembled, the surface left in the bore of the wheel is of a friable nature, and the tooled surface gives too readily to the compression exerted in keying up. Considering the accuracy and economy of modern grinding, it is rather peculiar that methods have not been revised. Where such work is of reasonable size and in quantities, there seems no valid reason why keyways and keys should not also be procured.

Taking by no means a methodical view of the subject, a small surface grinder and magnetic chuck at the disposal of the erector would prove of valuable assistance and eliminate much wasted labor. Instances are plentiful where three men, two sledge hammers, a couple of 6-ft. pinch bars, splintered wood packing, hard breathing, added to sundry curses, are required to remove a key in process of fitting in a job of some size.

On repair work such methods are necessary, but in building new engines it is neither creditable to the shop nor meritorious in the management to allow such procedure to persist. It may broadly be stated that a flywheel properly fitted and keyed with intelligence simply cannot work loose. The fact that the phenomenon is not infrequent points to irrational methods. If wheel and shaft are duly proportioned with adequate surfaces in actual contact, fastened by keys of similar qualification properly driven home, there can be no question of the undesired slacking back.

For obvious reasons the assembler or erector will always have the last word on the subject of keys, but more refinement in method and less muscle would seem beneficial all round. It is perfectly possible by simple hydraulic or screw means to withdraw a jib-head key in process of fitting by the unaided effort of one man. Simple easing with a file is permissible, but the need for $\frac{1}{8}$-in. reduction at the vise by hand is not unknown in repetition work of the character under discussion. The ancient method utilized a piece of wood to fit the key space; the smith then forged a key thicker by a paper all over. Such a key would require little time to make a first-rate job. Under modern conditions of making for stock, insufficient attention is paid to the waste of time in erection due to cumulative errors in the machine shop or divergence in size of blank keys.

The contention advanced is not that making up for stock is wrong; but that with standard sizes for keys, broaching methods and grinding, the fitting of a key should be a matter of minutes only. The modern divorce of the machine shop from erection and the making up for stock are not without drawbacks. The former is mainly concerned with cheap removal of metal, the latter with the purpose of the finished job.

The internal broaching machine gave us a cheap means of keyseating bores, the traversing slot miller a corresponding means with regard to shafts; yet unless the point is closely watched, there is apt to be a want of correspondence between the two parts.

In a well-designed engine the portion of the shaft carrying the flywheel is for reasons of strength frequently enlarged. There seems therefore no reason why the broaching operation for final size should not be carried out with the wheel mounted. If such a system is in vogue, it is certainly not universal practice and might even in the case of large work be more generally employed. Under such conditions keys might be carried in stock surface-ground to fine limits and comparative interchangeability assumed. The erector under such methods could fix and fit a flywheel in a fraction of the time often needed.

It is, after all, simply a revision of method required, for which standard and commercial means are already available, giving easier work to the erector, cutting time out of an expensive operation and benefiting incidentally the finished fit. A. L. HAAS.

Tooting, England.

[There are several manufacturers of finished machine keys in the United States. These keys are ground within a limit of 0.001 in.—Editor.]

Bevel-Gear Grinding Chuck

Quite a number of gear-grinding chucks have already been illustrated in the *American Machinist,* but this article describes how a simple form of bevel-gear grinding device can be easily made.

Most gear chucks have carefully shaped tooth forms, in order to hold the gear while the bore is being ground. This takes time to secure sufficient precision so that accurate gears can be ground.

As may be seen in Fig. 2, by using a straight cylindrical rod *A* no tooth-shape filing and fitting will

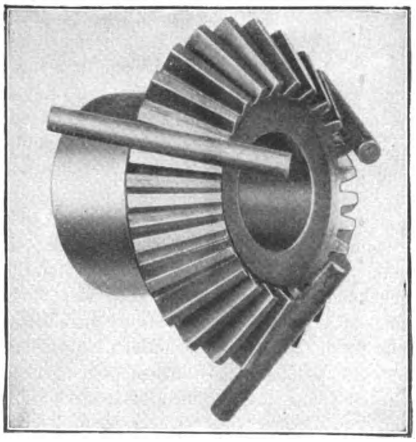


FIG. 1. BEVEL-GEAR GRINDING CHUCK

be necessary, and a simple reliable grinding fixture can be made in a short time. Actual experience proves that it is not necessary to have a tooth shape in order to grind bevel gears exactly.

Fig. 1 illustrates three cylindrical rods placed in position. The gear is clamped down on the rods *A* in the chuck, as in Fig. 2. The pitch line of the gear does not rest on the rods *A*, but simply rests along the tooth space, regardless of the pitch angle.

Fig. 2 shows how the gear is held in the chuck while being ground. *A* is a cylindrical tool-steel rod hardened and ground. Only one rod is shown, but three are used in this case. More should be employed on larger gears. *B* is the chuck body, made of cold-rolled steel. For larger sizes cast iron will do. *C* is a T-bolt and pivots on a pin. *D* is the clamp screw, which also pivots in the same way as *C*. *F* is a knurled locknut and is countersunk in the strap, as at *M,* so that, in case the nut loosens, the strap *G* would not open by itself. The strap rests on the gear at the center, shown only at *H;*

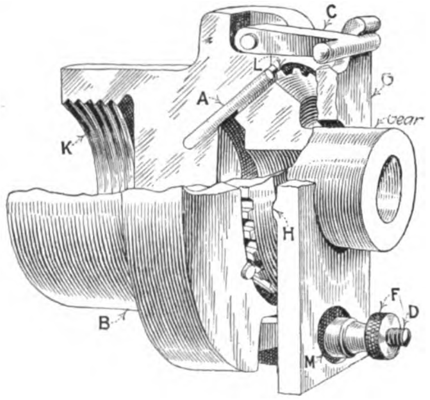

FIG. 2. CHUCKING THE GEAR

K is the thread, which usually fits on the grinder spindle. The chuck is made so that the gear has about $\frac{1}{16}$-in. clearance from the face angle of the gear, as *L.*

In making the chuck, the body *B* is first machined in the usual manner. Before the nest for the gear is turned out, the holes for the rods *A*, Fig. 2, are bored, and then the required amount of stock is removed. The size of the pins should be so selected that, when the nest is bored, with the necessary clearance for the gear, there should be about one-quarter of the hole left to keep the pin in proper position to rest in. No screws are necessary. The pin should have a drive fit.

To set up for drilling and boring the holes for the rods, the best way is to screw the pins *A* on the gear and set the machine up according to the natural position the pin would take, as in Fig. 1 (screws not shown). No dividing head should be used. CHARLES EISLER.

Bloomfield, N. J.

Crowning a Wooden Pulley

The top of a drawing table frequently becomes rough with the innumerable holes made by thumb-tacks. These holes can very readily and satisfactorily be filled by sprinkling some fine sawdust over the top of the table, brushing it well into the holes and then applying shellac.

A wooden pulley, which did not have enough crown to hold the belt, was just a little too large to swing in the largest of the ordinary manufacturing lathes and have a crown turned on it. It was finally concluded to try building a crown on the pulley by the method just described. After shutting down one evening, a crown was built on the pulley with some sawdust and glue (instead of shellac, as in the other case) and allowed to stand overnight. The next morning the pulley was smoothed up with a piece of sandpaper, the belt put on and started up. This pulley was repaired over a year ago and is still in good running order.

Middletown, Ohio. W. E. SHARKEY.

Discussion of Previous Question

Machine-Shop Oil Cans

The article by A. D. Vance, on page 325, is of more than passing interest, because it shows clearly that finality has not yet been reached regarding rational design of machine-shop oil cans. As in many other matters, this condition is possibly due to lack of study and consideration on the part of manufacturers or in the blind following of precedent.

About two years ago I designed some spring-bottom oil cans for our machine shop. They differed somewhat from those referred to, although they were made with a view to achieving one of the same results—namely, to prevent the much too frequent annoyance due to the oil cans rolling off the machines, benches, etc.

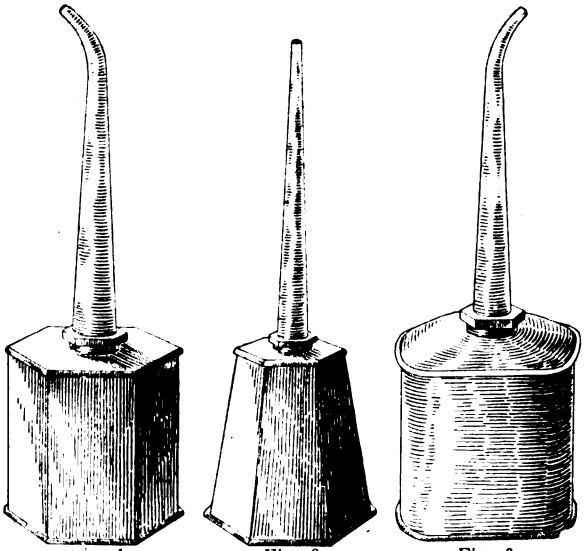

Fig. 1 Fig. 2 Fig. 3

MACHINE-SHOP OIL CANS

Every well-regulated machine shop should contain a supply of efficient oil cans; suitable places should also be provided in which to keep them when not actually in use. This enables the mechanic to put his hand on a can at once instead of roving around the shop, as is often the case. Figs. 1, 2 and 3 show spring-bottom oil cans that vary from the type usually made by oil-can manufacturers. These cans are easily made by hand with a few tools and at little cost of material. Should large quantities be required, seamless bodies could readily be produced in modern drawing and forming dies.

An oil can of hexagonal shape, with straight sides, is shown in Fig. 1. Fig. 2 represents a similar can with taper sides. This style is preferred by the machine men. The can illustrated in Fig. 3 is also very serviceable and can be made with taper sides if desired.

Rectangular or square-shaped oil-can bodies of suitable sizes, having square or round corners, will be found to have an advantage over the usual cylindrical form. The square bodies could be strengthened by corrugations if necessary. Thin hard-rolled sheet brass is a suitable material for the bottoms. The springiness, or diaphragm action, is readily obtained by careful hammering after the edge has been bent up to fit the body. The bottom should be struck about a dozen blows with a smooth-faced hammer on a bright anvil, just round the center, to cause a slight buckle. It is then soldered to the body, care being taken that the soldering iron is not too hot. The bottom must not be pressed until thoroughly cold.

Manchester, England. A. EYLES.

Wanted--Data on Cylinder and Piston Grinding

In reply to the inquiry on page 860 by A. D. Marcotte, regarding the grinding of cylinders, I submit my experience. Some years ago I was with one of the big motor companies and had a lot of trouble trying to get production on cylinders. We had two grinders which should have given an output of 35 to 40 cylinders per machine per day. We were getting only about 25 per day off both machines.

The trouble was that the cylinder nose was finished before boring, to fit a fixture for holding it on the boring machine, and the strains of the boring operation were such that the nose was out of alignment when the cylinder came to the grinder. It was impossible to grind without adjusting for every piece.

During the process of carrying the job through the different operations in the factory the back of the flange was faced off to make a smooth seat for the nuts holding the cylinder to the crank case, and 0.010 in. was left on the cylinder nose. The back of the flange was then turned off and the nose also finished in size. This was done on an expanding arbor in a lathe, which enabled us to reduce the grinding limit to 0.010 in. for the bore of the cylinder, thus doing away with the adjusting on the grinder and increasing our output up to 100 cylinders per day of 10 hr. JOSEPH A. DALTON.

Brooklyn, N. Y.

Take Warning!

With much interest I have watched the results of the warning given in these columns regarding the proposed change of our standards of measures to the metric system. Owing to the fact that my work requires very little use of the metric system, I have heretofore given it but scant attention. From those with whom I have discussed the question I have failed to learn any material advantage to be derived from the use of the metric system over the English standard.

There is nothing done in measuring or figuring measurements by the metric system that cannot be done just as well and sometimes better by the English standard. Expressing a measurement in metric units entails more work than giving it in English units.

To say a bar of metal is eleven millimeters in diameter takes longer than to say it is half-inch, quarter, three-quarters or inch, and one grasps more readily the meaning of the latter. Speaking in metric terms requires the expression of the "unit" (millimeter) to convey the meaning, whereas in the usual shop parlance of the English standard it is just sixty-two and a half (0.0625 in.), or one-sixteenth, one twenty-fifth (0.125 in.) or one-eighth, for measurements less than an inch.

Units of the English standard expressed in decimals automatically divide inches, feet, yards, etc., into tenths, hundredths, thousandths, etc., which gives the same method of computation as does the metric system.

The idea of changing an old, tried and adopted method for something "just as good" is very much like adopting the vertical system of writing in place of the Spencerian system. No doubt its sponsors thought it was the "upright" thing to do, but it eventually "fell down," and the prettier style exists to prove its worth.

In spite of the fact that the units comprising the English sysem are not tens and divisors of ten, it is a system that makes measurements easily computable. While some may have trouble in learning fractions, the decimal system as applied to the English standard gives a simple and easily learned method of computation. The 2-ft. carpenter's rule is a splendid example of a way to become familiar with fractions, and our dollar and cents coinage gives a clear understanding of decimals.

Rochester, Minn. GEORGE G. LITTLE.

Taper-Shank Drills

There appeared on page 554 an article regarding taper-shank drills, which ought not to go unchallenged. Mr. Spence says that the taper should change from No. 2 to No. 3 at ¾ in. diameter instead of $^{59}/_{64}$ in., and from No. 3 to No. 4 at 1 in. diameter instead of $1\,^{17}/_{64}$ in. I think this would be an expensive and unnecessary change. In each of these cases it would require about twice as much steel, with most of it simply turned to waste. The result would be that the cost of a drill would become more nearly prohibitive than ever, and I should say the difference is more than your correspondent has allowed for.

Regarding the necessity for a change owing to broken tangs, my experience has proved to me that it is very often improper use that causes a tang to twist or break. Badly worn sockets, whereby the tang takes all the strain instead of the shank taking its share by being a perfect fit, is a frequent cause. In proof of this I have seen a $\frac{11}{16}$-in. drill with a No. 3 shank, with the tang twisted badly, and yet I drilled through the work with a standard drill (No. 2 shank) simply by making a properly fitting socket. I have never yet seen anything to warrant a change from the Morse standard. A. P. MOORE.

Sheffield, England.

Standard Product Inspection

The article by J. A. DeTurk and S. H. Radabaugh, page 591, is full of interest to me and should be to all chief inspectors. Of course, we all know there are chief inspectors who have been "pitchforked" into their berths because of their mathematical training and others who have been "through the hoop" in the workshops. Of the two, give me the latter. He is the man who knows. The former is the man who first "assumes" and then deducts from his assumptions.

I quite agree with the authors of the article when they say that only limit gages should be used in the shops and not micrometers, which are so liable to wear and which always have the uncertain errors of judgment in "feel." Their last remarks are also true, that chief inspectors should be responsible to the general management and that a good inspector will "work with the production department, not against it; he must be a good mechanic, and must be decisive in character, even-tempered, firm, fair-minded and—a gentleman."

I have in mind a large ordnance firm in Great Britain where the chief inspectors of each department were controlled by that department chief, with the result that either the inspectors resigned or remained dissatisfied and consequently got a bad name all round. In one large concern manufacturing munitions, the chief tool inspector was, to my intimate knowledge, told by an imported refugee organizer from a large Continental electric firm to try out screw-machine form tools on parraffin wax. The result was that the chief inspector left, having no one to appeal to. The refugee organizer was not far behind him.

Yes! A chief inspector should be well paid, well selected and have the backing of the management. He should have access to all departments for consultation, have great determination, excellent logic and be prepared to stake his job on his decision. R. L. HASELGROVE.

Buckshire, England.

Grinding Die-Setting Pins

I notice with interest the answer from Mr. Remacle, on page 915, to my article on die-setting or guide pins. I must take issue with him, however, on the superiority of hardened and ground pins and bushings over the method that I am using. Mr. Remacle, I am sure, has not tried using unhardened, natural, surface drill rod running in cast iron, or he would not think that the more expensive way would give the best results.

As I said in the previous article, I have followed the one method for five years on several hundred dies, many of them serving hundreds of thousands of times. A large portion of my work was on 90-lb. tin plate 0.009 in. thick, where the punch and die have to fit as close as it is possible to make them. I used very little metal over 0.035 in. thick.

As I had uniformly good results, I cannot see how any other method can be any better. I do not remember a single instance where the pins wore enough to shear the punches, even on the thinnest metal. In a number of cases I used the same shoe, punch, holder and pins for a second die and punch after the first had been broken or worn out.

Of course, Mr. Remacle is right about the method of drilling and reaming, inasmuch as a good miller is certainly more accurate than a drilling machine. We had no miller, however, and succeeded in getting good results with the drill. It was not very old and had been well taken care of. We made many small dies, which could be separated without the aid of jacks, although we did not always do it, by any means. W. B. GREENLEAF.

Plymouth, Mich.

Theory and the Engineer

Hardly a day passes in these busy times without the announcement of some new scientific principle that is to revolutionize some industry. It may be a new process for obtaining gasoline or even a substitute for this fuel; it may be a new mode of propelling submarines or a method for making aniline dies; it may be a machine tool or a shop process; but always there is a large proportion of the public and frequently not a few men of considerable scientific attainment who are ready to believe that the step is only a short one between the principle or invention and its successful industrial application.

We who spend much of our time describing the work of other men's hands and brains know what a long road there is between the laboratory and the workshop and how many are the obstructions in the way. It is the prime function, if not indeed the life work, of the engineer to remove these obstructions and to span the gulf that lies between what has been called "raw" science and industrial science. We look upon the present-day perfection of the electric motor, the loom and the printing press or even the simpler marvels of the dictaphone, the camera or the oil motor, but how few of us appreciate the enormous number of practical difficulties encountered or the prodigious amount of thought and work expended before the original principle could be converted into a practical remunerative enterprise.

Even after the original conception has graduated from the "raw" science stage and has been tested out under so-called commercial conditions, it is always exceedingly difficult for the combined efforts of inventor and engineer to find a financier with the courage to stand behind the venture and the patience to wait for a return that is hardly ever immediate.

Bacteria in Cutting Oils

Of late these questions have been frequently asked: What information have you in regard to the presence of dangerous bacteria in cutting oils? What do you know about the need and methods of oil sterilization? But few data have been published that might answer these queries, although observation in shops leads to the belief that infection frequently comes to screw-machine operators from the oils with which their hands are constantly covered and that careful shop management calls for the sterilization of all cutting oils. Some light is thrown on this matter by a few facts submitted by the Richardson-Phenix Co.

This firm has made examinations of many samples of cutting oils used in different machine shops, and it reports that bacteria are invariably found. Recently a sample was taken from a plant where the sanitary conditions are above the average, and submitted to careful study. The general results are these:

Before treatment the bacteria count was 24 per cubic centimeter of oil. After heating for 20 min. at a temperature of 80 deg. F. the bacteria count was 22 per cubic centimeter; heated for 20 min. at 100 deg. F. the count was 15; heated for 20 min. at 120 deg. F., the count was 8; heated for 20 min. at 140 deg. F., the count was 0.

In each case the counts were made after incubation for 48 hr. at 37 deg. C. (98 deg. F.). As there was no growth in the portion of oil heated at 140 deg. F., after incubating for 48 hr. at 37 deg. C., another portion of the oil was heated at 140 deg. F. for 20 min. and incubated for 24, 48, 72, 96 and 120 hr. At the end of every 24-hr. period of incubation the oil was examined for the growth of bacteria. At each of these examinations and at the expiration of the 120 hr. no growth had appeared.

In kind these bacteria are tuberculosis and ordinary dirt bacteria. The conclusion reached from the study mentioned is that heating oil to a temperature of 140 deg. F. for 20 min. is enough to kill most of the common bacterial growths. Experience has also shown that if the shop is in a thoroughly satisfactory sanitary state the sterilization of the oil is necessary only about once in two weeks. Of course, frequent examinations should be made to determine its conditions and sterilization performed when necessary.

At the same time it should be observed that the bacteria count in none of the cases cited is very high; in fact, compared with the bacteria present in ordinary drinking water, it is low. Yet the fact that dangerous bacteria may and do exist in cutting oils is sufficient warrant for shop managers to study their own factory conditions and determine for themselves whether or not they should provide means for cutting-oil sterilization.

The Business Man and the Technical Journal

Not long ago we heard a "captain of industry" and a scientist lamenting because the reading of technical periodicals has become so universal and complaining that it absorbs much of the time of the readers. Because of these two facts, they went on to say, the quiet and thorough study of well-written books has been forsaken, and readers nowadays get only a superficial and desultory knowledge of the things they study.

We think the conclusions are hardly sustained by the large array of facts relating to them. We doubt if good technical books ever found a more ready market than now. It would be well-nigh impossible to collect reliable statistics on the subject, but our impression is that through the universal diffusion of current technical literature and the knowledge of books conveyed and advertised by it the book trade has been rather helped than harmed. We do know that 133,000 copies of technical books written from material that originally appeared in the *American Machinist* have been sold. Very many technical books would never reach the world but for the introduction and commendation of the periodical.

Librarians are busier than they ever were; scholars are no less studious than formerly; science was never more active in its investigations; discovery was never pushed more efficiently and enthusiastically. Truly, the facts hardly sustain the conclusions of those who decry the technical periodical.

To the man absorbed in business and practical affairs who can spare more time than that demanded by his daily paper the technical journal brings every week or month the latest investigations and their application and enables him to keep pace with his contemporaries. If the work of the various active scientists of the day were embodied only in elaborate books, he would seldom see or read one of them. In the periodicals all the scientific men of the world meet. They learn there what each man is doing, while all the interested world studies them and keeps in touch with their work. Indeed, we do not know of any class of men who would be more affected by a suspension of periodical technical literature than those same business men and scientists who sometimes speak so harhly of it.

The First Years After College

About this time every year thousands of young men are leaving college to enter upon active life. They are ambitious, confident of their ability, hopeful; and yet in the great majority of cases the prospect is most perplexing, to say the least. They look along the avenue of prosperity and see all the posts occupied, the offices filled, the paths crowded, and they wonder where they can find room. If they will but gaze over the heads of the crowd, however, a little farther along the avenue they will see great open spaces where the occupants are never crowded. Messrs. Schwab, Corey and Frick are never troubled for space at their elbows. Professions are never crowded near the top. There is always room to spare where the experts are.

It is in the order and nature of things that the first few years of every man's business or professional life are years of education. It is these years that teach him what is in him, drill into him a patient and persistent habit of work and give him the strength to hold all the ground gained. Doors seldom open to the man who has not prepared himself to enter them. By the same token, when a man has thoroughly prepared himself for a higher place, the door to that place usually swings back of itself.

It is true that only a few can reach the top, but it is also true that the farther from the bottom the fewer the company. It is as if each calling were pyramidal in its human constituency; and while only one man is at the top, there are several tiers of men below him who have ample space. It is only at the base that men are so numerous that they crowd and jostle each other out of the fairway into the bypaths. If a man does not develop the ability to lift himself out of this crowd at the base, it seems reasonably certain that he is not adapted to his chosen calling.

It is in those first few years that young men know the only leisure they will ever know. They are golden years that should be filled with systematic reading, social intercourse and ceaseless observation. Afterward they will become absorbed in too many business and family cares to find time to pursue such habits, and when they look back at the lost years it will be too late.

The work of the world seeks the hands best fitted to do it, just as naturally as water runs down hill; and the question whether a man is to rise above the rabble at the base of the pyramid will be decided by the way he improves those first few years after college in acquiring the thorough knowledge of his profession always possessed by those at the top.

The Value of Praising

There seems to be an indefinable something about all engineering plants, particularly the metal-working shop, that after a while prevents those occupying supervising positions from praising where praise is due. Whether it is because the supervisor becomes more or less influenced by his constant association with so much mechanism that he unconsciously treats men as part of it or whether it is that the workmen seem for the most part lacking in those finer, more delicate sensibilities that appear to respond appreciably to an occasional word of praise is unimportant; but it is certain that even the occasional word is seldom spoken. Hereby a great mistake is being made.

Many shops are full of men unhappy in their work and producing but a fraction of their possible output for want of a little judicious praise. They have little faith in themselves and need assurance of their capabilities from others, especially their supervisors. It is a popular notion that much self-esteem is a common weakness and that men do not require others to comment favorably upon their efforts. We are confident, however, that a large part of what appears to be vanity or egotism is the very opposite. It is only an uneasy or frantic attempt to win from others an assurance of what one himself sorely doubts. How unfortunate then that supervisors in their various dealings with the men under them are so sparing of praise!

How often have some of the best workmen left a plant for a few cents more a day at some other shop, when a word or two of praise would have held them. It is true that praise is sometimes dangerous, but so is blame. So are firearms and locomotives and flywheels; so is everything useful. But would one banish sunshine because it sometimes causes forest fires? No doubt "it is poison to a human soul to breathe the incense of praise habitually," but praise and overpraise are two different things. The former, when justly bestowed, always stimulates.

The higher the class of labor the less grudging should we be with our praise. This is so because it has been truly said that sensitiveness to merited praise may be almost regarded as an exact measure of the delicacy of the civilization. The civilized nature is sensitive all over, and therefore the more highly developed the workman the better the result that may be expected from honest commendation.

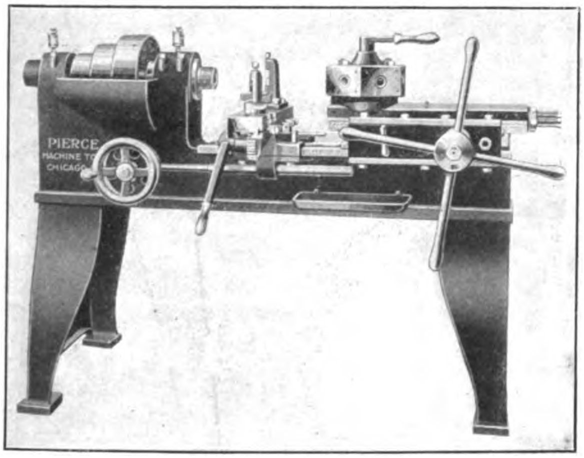
Like many other good things where a little goes a long way, that little must be of the purest kind and free and full. A French moralist has gone so far as to say that "it is a great sign of mediocrity always to praise moderately." We have heard from our childhood the expression "to damn with faint praise." Habitually to withhold commendation where it is deserved, to praise faintly where there is signal merit, to be always afraid of committing oneself and of being asked for a raise in wage argue a narrow head, to say the least.

Shop Equipment News

Hand Screw Machine

The illustration shows a 1-in. hand turret screw machine, with plain head, recently developed by the Pierce Machine Tool Co., Chicago, Ill. In both the design and construction the chief aim has been to provide a machine of sufficiently heavy proportions to insure rigidity in operation.

The headstock is of bowl-type construction, cast in one piece with the bed. The automatic chuck is forged solid on the end of the spindle with external thread. The small amount of overhang from the front spindle bearing is designed to abolish the tendency to vibrate. The machine is arranged so that the plain round solid collets can be used, or a master collet can be furnished adapted to hardened bushings.



HAND SCREW MACHINE

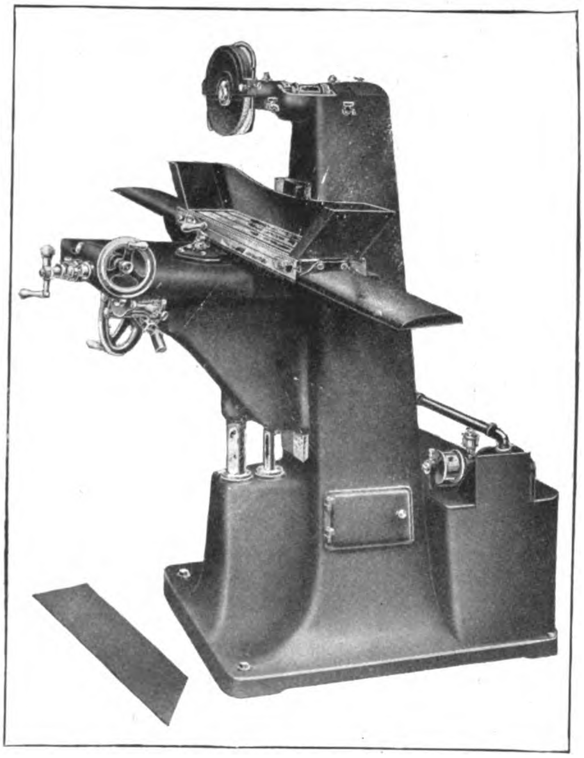
Capacity, automatic chuck, round, $1\frac{1}{16}$ in.; capacity, threaded work on soft steel, $\frac{5}{8}$ in. U.S.S.; capacity, pipe threads in brass up to $1\frac{1}{16}$ in.; capacity, drilling in soft steel, $\frac{3}{4}$ in.; hole in automatic chuck plunger, $1\frac{3}{32}$ in.; hole through spindle, $1\frac{5}{16}$ in.; length that can be turned, 8 in.; greatest distance, end of spindle to face of turret, saddle flush, $16\frac{1}{2}$ in.; diameter of turret across flats, hex. $7\frac{1}{2}$ in.; distance, center of turret holes to top of slide, $2\frac{3}{8}$ in.; travel of cutoff, longitudinal, $8\frac{1}{2}$ in.; width of driving belt, $2\frac{1}{2}$ in.; extension of bar feed rod, 3 ft. 4 in.; width of countershaft belt, 3 in.; cross face, 2 ft. 2 in. by 5 ft.; weight, 1,350 lb.

The cutoff rest has a good bearing on the bed, is provided with hand longitudinal screw-feed adjustment, arranged with micrometer dial and observation stops.

The turret, hexagonal in form, is fitted with six tool holes with binder bushings and also provided with bolt holes for securing the tools to the face of the turret, as well as counterbored to receive a boss on the back of the tool. The turret holes are arranged with holes through the turret stems, allowing the stock to pass through up to the full diameter of the hole. The locking bolt for the turret is fitted at the front end of the slide, directly under the cutting tool, and works in hardened and ground taper bushings let into the solid turret, as near the periphery as practicable. Independent adjustable stops for each position of the turret face operate automatically.

Wet or Dry Surface Grinder

A single-wheel machine on the same lines as the double grinder illustrated on page 617, has been brought out by the Grayson Tool and Manufacturing Co., Indianapolis, Ind. In fact, this machine may be considered as one-half of the Duplex machine there shown. It has the same spindle construction, similar feeding mechanism and the same size of table. It is equipped with a three-speed countershaft, so as to drive wheels from 2 to 8 in. in diameter at their proper cutting speed.



WET OR DRY SURFACE GRINDER
Table, $6\frac{7}{8}$x20 in.; cross-movement, 7 in.; travel, 20 in.; wheels, 2 to 8 in.

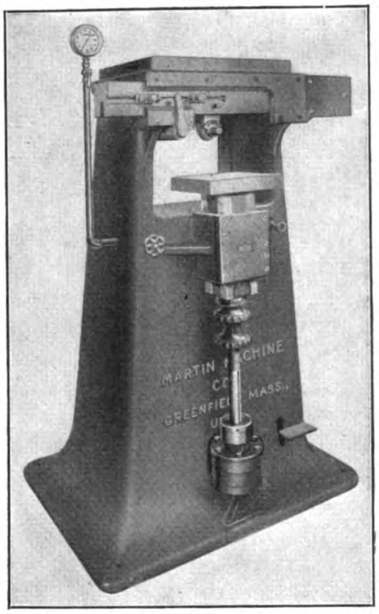
The guard for wet grinding is shown in place on the table, the front piece being on the floor by the base of the machine. This guard can be easily removed, when desired, for dry grinding.

Two of the new features are the inclosing of the vertical screw and the drive shaft in telescoping tubes to protect them from grit and dust, and the use of cushion springs in the table dogs for eliminating shock and noise during reversal. The sliding ways on the face of the column are cast in a chill to close the pores against the entrance of dust. Felt wipers, top and bottom, aid in keeping the wearing surfaces free from foreign particles of any kind.

Hydraulic Marking Machine

The marking machine shown was designed for marking round or flat surfaces and incorporates as a special feature hydraulic control.

The adjustment of the table is provided with a set of ball-bearing thrust collars which relieve the locknuts of the pressure, therefore allowing them to be free and easy to move by a slight turn of the hand. Both table and slide are provided with gibs. Regardless of what part of the table the work may be placed, the stroke of the slide may be varied by two adjustable stops and set to a position desired. The entire drive depends upon a small pulley at the rear attached to a pump driven by a $1\frac{1}{2}$-in. belt.



HYDRAULIC MARKING MACHINE
Travel of slide, 8 in.; adjustment of table, 6 in.; floor space required, 30x24 in.; weight of machine, 950 lb.

All adjustments of the machine are within easy reach of the operator when standing before the machine, where the work is plainly in view.

The working operations are placing the work to be marked in position and starting the machine by pressure on the foot treadle at the right, which opens a valve, allowing the pressure of the oil to raise the table. The die then traverses the work and at completion of the forward stroke the table drops, the work is released, the die returns to its first position and the machine stops, unless continuous operation is desired, which may be had by keeping the foot on the treadle.

An oil tank in the base supplies the oil to the hydraulic cylinders. The oil is pumped by a small rotary geared pump at the rear of the machine through a relief valve set to give any pressure desired, indicated on the gage at the left of the machine.

The oil, being held back under pressure, goes to the operating valve. In one position the oil passes through the pipes to the cylinders, raising the table to the working position and flowing through the hollow piston rod to the slide cylinder, which forces the slide on its outward stroke. The exhaust flowing back through the valve into the tank, until the operating valve is shifted automatically by the stop on the slide, reverses the flow of oil into the opposite ends of cylinders, forcing the table down and the slide back to the starting point.

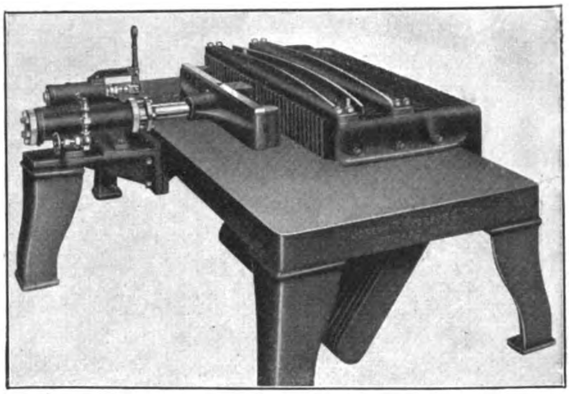
The speed by which the slide is traversed is governed by the supply valve at the left, which controls the amount of oil passing through the cylinder. Any speed between 0 and 225 ft. per min. with a pressure of 75 lb. may be obtained.

The type of machine shown represents a recent development of the Martin Machine Co., Greenfield, Mass.

Elliptic-Spring Former

The spring-forming machine shown was designed primarily for railroad-spring shop use. It will form elliptic-spring leaves of any size and curvature common in ordinary practice without changing dies.

The machine requires only one man for its operation, but may be used by two fitters working on different kinds of leaves at the same time. In the operation of the machine the hot spring leaf is formed next to the cold plate against which it fits in the spring, thus giving an accurate camber to the hot leaf. A second heat is not required for tempering, as the leaf is taken directly from the former to the oil bath.



UNIVERSAL ELLIPTIC-SPRING FORMER
Maximum stroke, 9 in.; table, 7x4¼ ft.; length of crosshead, 36 in.; height of dies or keys, 6 in.; floor space, 7½x6¾ ft.

The machine consists of a heavily designed horizontal table supported by five legs. The bank of keys which make up the female die is arranged at one end of this table, together with the male die, behind which is the pressure cylinder. The keys rest on edge, side by side, and are held in a forward position by a series of counterweight levers, which furnish the necessary pressure to set the hot plates. On the front end of the piston rod a crosshead is provided, which, coöperating with three blocks, act as a male die and offers the backing for the cold plate or templet.

The valve for controlling the movement of the plunger or piston is placed immediately on top of the piston when compressed-air operation is desired and immediately at the side of the piston, where operation is by hydraulic means. The cylinder itself is mounted on an extension of the table.

This machine is a recent addition to the line made by Joseph T. Ryerson & Son, Chicago, Ill.

Plain Cylindrical Grinder

The self-contained grinder shown in the illustration represents a recent product of the Perkins Grinder Co., Cleveland, Ohio. The control is designed to be centralized and automatic, and hand feeds are provided.

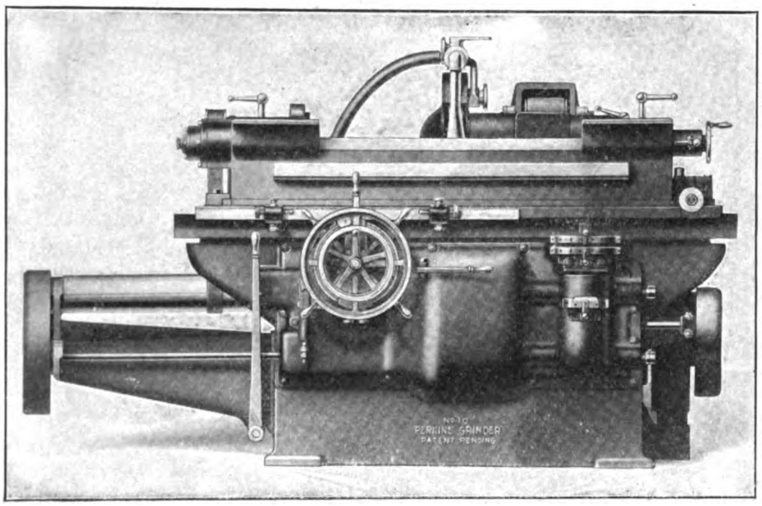
The main-drive shaft runs at a constant speed of 575 r.p.m. The power is applied from the lineshaft to a single-belt clutch pulley, or a motor may be connected direct to the main-drive shaft.

The control box is a separate unit. The work speeds and table feeds may be engaged or disengaged independently or simultaneously while the machine is running. The transmission and automatic table mechanism are two independent units, positioned in front of the machine and completely covered.

The transmission has 10 speeds for both work speed and table feed; no gears run over 80 r.p.m. All of the transmissions are always in mesh. The work speed, driven by a link belt, has 10 progressive speed changes—30, 60, 90, 120, 150, 180, 210, 240, 270, 300 r.p.m. The table traverse has 10 progressive speed changes—12, 24, 36, 48, 60, 72, 84, 96, 108, 120 in. per min.

The automatic crossfeed may be set to feed at either or both ends of the table traverse. A variable tarry device is arranged to tarry at each end of the stroke and can be regulated. The table traverse can also be stopped and started with the tarry lever.

For taper grinding, the table swivels and has two scales, graduated in degrees and thousandths of an inch. The work spindle is arranged for live and dead centers; the footstock spindle has a variable spring tension controlled by a handwheel and quick-acting lever. The backrest has both vertical and horizontal movement. Ball bearings are provided for the high speeds; the other bearings are lined with phosphor bronze. The ways and bearings are thoroughly protected.



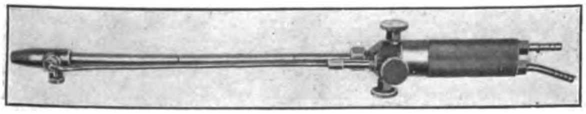
PLAIN SELF-CONTAINED CYLINDRICAL GRINDER

Maximum swing, 11 in.; maximum grinding length, 40 in.; diameter of grinding-wheel spindle, 3½ in.; width of grinding-wheel driving belt, 5 in.; diameter of grinding wheels, 18 in.; least reduction of automatic crossfeed, 0.0005; greatest reduction of automatic crossfeed, 0.005; diameter of driving clutch pulley, 12 in.; width of main-drive belt, 6 in.; power required, 15 hp.; net weight, 6,500 lb.

Welding and Cutting Torch

The form of torch shown was designed for a wide range of work and to be readily changed from welding to cutting.

The head is cast *en bloc,* to eliminate leakage. The cutting head can be adjusted to two different positions—a right-angled torch or a straight-ahead cutting torch—as shown.



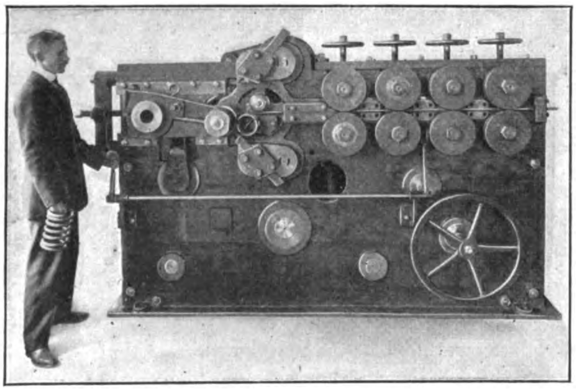
WELDING AND CUTTING TORCH

This torch is known as the "Hoover" and represents a recent product of the Oxy-Acetylene Products Co., Chicago, Ill.

Heavy Spring-Winding Machine

The illustration shows a spring-coiling machine built by Sleeper & Hartley, Inc., Worcester, Mass. It is adapted to make either extension or compression springs, and it is possible to feed 100 ft. into a single spring.

The spring is not produced by being coiled around an arbor, but by being fed forward by feed rolls against a coiling point or deflector, the machine putting a predetermined amount of wire into each spring. The machine is automatic, coiling and cutting alternately, the coiling mechanism being stopped while the spring is being cut off.



HEAVY SPRING-WINDING MACHINE

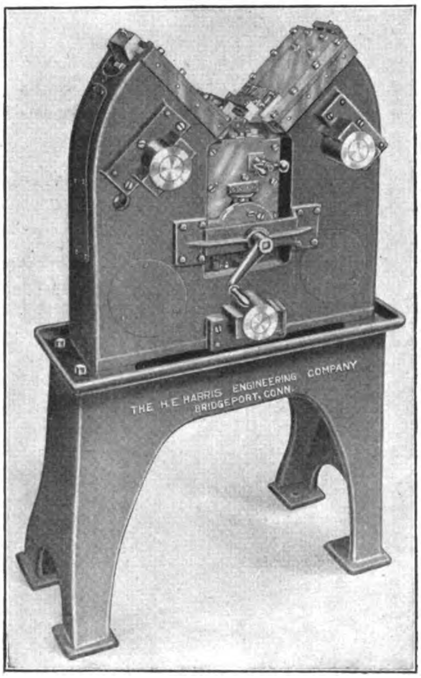
Capacity, ⅝-in. oil-tempered wire, cold; length of wire, 100 ft.; speed of wire feed, 50 ft. per min.; floor space, 6x8 ft.; weight, 16,000 lb.

The only function of the arbor is to provide a cutting edge against which the exterior cutter may carry the wire for the purpose of shearing it off after each coil.

In all these machines adjustments are provided for the feed or amount of wire which can be fed into any one spring; and of course the diameter and pitch, as well as the contour of the spring, may be changed instantly by means of adjustments provided.

Special Rifle-Sight Leaf-Notching Machine

The illustration shows a machine for notching simultaneously both edges of a Russian rifle sight. The machine has two diagonally disposed slides that carry 10 notching tools each. The slides are crank-actuated at an average speed of about 6 ft. per min. The tools



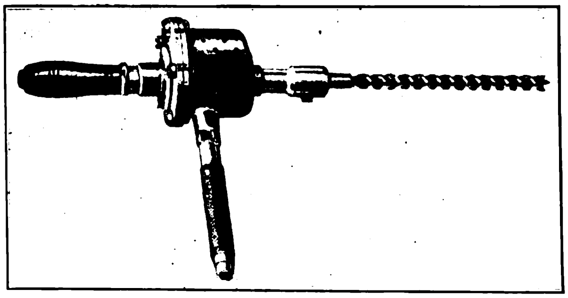
RIFLE-SIGHT LEAF-NOTCHING MACHINE

are held in accurately made tool holders. When individual tools become worn or break, they are replaced by others, as with the accurately shaped tools and tool holders the relationship between tools can be readily maintained without replacing the whole set-up.

This machine is built by the H. E. Harris Engineering Co., Bridgeport, Conn.

Pneumatic Wood-Boring Machine

This machine was originally designed for boring holes in railroad-car work, ship frames and wood-frame structures of all kinds. It weighs but 6 lb. and will

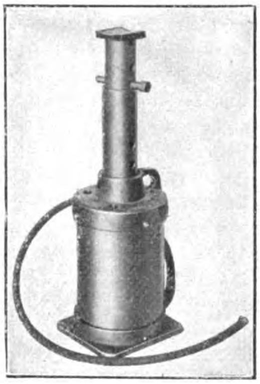


PNEUMATIC WOOD-BORING MACHINE

bore holes up to ¾ in. in diameter through oak or pine sills at the rate of 1 in. per sec., with 90 lb. air pressure, The bit runs at 2,200 r.p.m. It is not likely to get out of order, as there are only five principal parts in it, including the operating handle. It is made by the Baird Pneumatic Tool Co., Topeka, Kan.

Pneumatic Lifting Jack for General Service

This lifting jack may be used for raising an automobile or for various jobs around the shop. It may be operated by an ordinary automobile tire pump or from shop air connections. It has a minimum height of 10½ in. When the piston is extended, it reaches to a height of 16 in. A central telescoping piece can be raised two additional inches, making a total height of 18 in. when desired. The piston will stay in any position in which it is placed until the air is released; but for additional safety, holes are drilled crosswise through both the piston and the telescoping piece. The latter, of course, must be locked with a pin in any case when raised, but with the piston itself it is optional with the operator. The jack weighs 10½ lb. and is made by the Baird Pneumatic Tool Co., Topeka, Kan.



PNEUMATIC LIFTING JACK

European Women and Our Labor-Saving Machinery

A study of the economic and financial conditions immediately following the great wars of modern history—the Napoleonic wars, the Crimean, our Civil War, the Franco-Prussian, the Boer and the Russo-Japanese wars—in comparison with the vast struggle now raging in Europe has convinced a number of writers and speakers on business subjects that, far from being threatened with acute depression, Europe will be more likely to see, when peace is concluded, a period of commercial activity and prosperity. It is pretty generally agreed that, whatever the economic readjustment, there will be a much increased use and invention of labor-saving machinery all over the war-torn lands of Europe.

The substitution of the labor of women and girls for the more muscular toil of men on the older continent, we are told, will necessitate a great deal of labor-saving machinery. We Americans, by general admission, produce the best of such machines. Will the vastly increased employment of women in Europe have a deep and lasting effect on American business? This is but one of the searching questions put to us as far-sighted business men by the great war. It seems apparent that the readjustment that will take place in Europe will have a marked industrial influence in America.

Panama National Exposition

By Frank A. Stanley

SYNOPSIS—This exposition, opened at Panama City a short time ago, will retain two of its buildings—namely, those of Spain and Cuba—as permanent structures, and most of the exhibits in them will also be kept as of lasting interest. There is little shown in the way of machinery, but plenty of interesting objects reveal the natural resources of the republic. It is said that the United States Government exhibit is the greatest one ever shown abroad by this Government.

The national exposition that opened at Panama in February occupies a site above the beach along the Bay of Panama on the shore road to old Panama City. This exposition, which has as its Director General an American, James Zetek, of Chicago, was undertaken with the object of celebrating the opening of the Panama Canal and commemorating the discovery of the South Sea by the Spanish explorer Balboa. Its principal structures, seven in number, arranged in squares about a central plaza, are the Hall of Fine Arts, the Administration, Commerce, Agricultural and Horticultural Buildings, the Education Building and the permanent buildings of Spain and Cuba. The latter two after the expositon closes are to be utilized as the homes of the legations of the two countries mentioned. It is probable that most of the exhibits in them will remain as articles likely to be of lasting interest.

An interesting feature of this exposition is the fact that the exhibit of the United States Government is the most complete and comprehensive one that this Government has ever sent to a foreign country. The entire Government display was transferred bodily from the Panama-Pacific Exposition at San Francisco and, as most of our readers are aware, includes exhibits from every governmental department, the most noteworthy being those of the army and navy, the Geological Survey, the Bureau of Standards, the Panama Canal, Public Roads offices, Bureau of Mines, Bureau of Fisheries, Bureau of Education. Among the items that are most likely to attract attention are the army and navy collections, particularly the latter, in which models of all kinds of ships from the earliest times are shown, including the most primitive and the most uptodate warships, among them battleships, cruisers, destroyers, colliers, submarines, etc. Similarly the showing of the United States Army is of importance from a contemporary as well as a historical point of view, as it represents a complete record of arms from the old arquebus to the modern high-velocity military rifle and the rapid-fire gun.

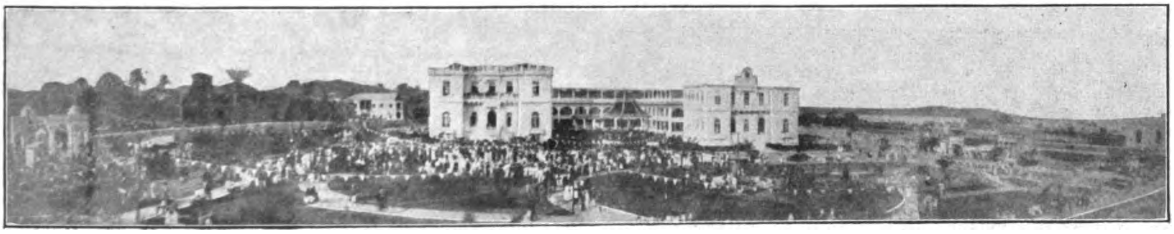


FIG. 1. PANORAMA OF PANAMA NATIONAL EXPOSITION

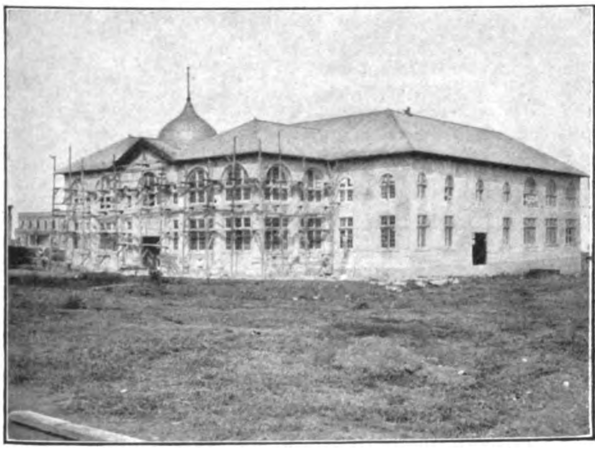

FIG. 2. EDUCATION BUILDING

FIG. 3. AGRICULTURAL BUILDING

An important characteristic of most expositions nowadays is the statistical chart, calling attention to various stages of progress in human activity. One in the Bureau of Education will probably be a surprise even to widely traveled Americans, who little realize the number of schools in this country. This summary points out that there are 20 great universities in the United States and about 800 of less importance; when it comes to the country—that is, the rural schools, say those having one teacher each—there are 212,000. Other exhibits of inter-

est in this connection come from the public schools of Denver, Chicago, Los Angeles and other widely separated cities of the United States, each showing something distinctive in character and well worked out in application.

While taken as a whole the exposition has comparatively little from the strictly engineering viewpoint; there are some things of immediate interest to readers of a mechanical turn of mind and quite a good many features worth while to visitors with a broad point of view.

In the panoramic view of the exposition grounds, Fig. 1, the Commerce Building will be seen in the foreground in the center of the picture, the Fine Arts Building at the right and the Panama Government Building at the left. The Education Building as it appeared shortly before completion is seen in Fig. 2 and the Agricultural Building in Fig. 3, these illustrations giving a good idea of the architecture of the principal structures.

Visitors to Panama for the first time undoubtedly have found the most important feature of the exposition to be the exhibits of the natural resources of that republic. Great pains have evidently been taken by the directors to gather as complete a line of natural objects as possible,

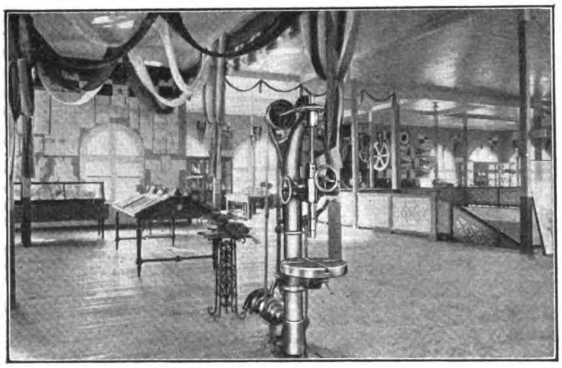

FIG. 4. DRILLING MACHINE AND TOOL MADE BY STUDENTS

and this is demonstrated by the hundreds of varieties of high-grade cabinet woods and timber woods exhibited. Travelers through Panama state that there are millions of acres of tropical forests densely grown with most valuable woods that yet remain practically virgin timber. The diversity of woods here is well suggested by the fact that among the samples shown are some that are lighter than cork and others heavier than water.

There is no great number of machine shops and foundries in the Republic of Panama; and as had been expected, the exhibits of mechanical objects are few and far between. There are, however, a few such appliances from local establishments and from schools for teaching trades, arts and crafts. Among these may be mentioned the exhibit of the Panama School of Arts and Crafts, which occupies a considerable area and shows most commendable work. Among the exhibits are a number of electrical supplies, such as wall lamps, heaters, etc., and a vertical drilling machine, illustrated in the foreground of Fig. 4, the background of the view representing a number of castings and forgings of various kinds produced at the school. These include metal-cutting machines, brass and copper tools, brazed shells, decorative objects and a variety of other articles. Also a good many examples of high-grade woodwork are exhibited and many mechanical and architectural drawings.

Naturally no exposition at Panama would be complete without a representation of the strides made in general sanitation and the elimination of diseases, such as yellow fever and the plague. It is possible here to follow the history of the yellow-fever mosquito, as the insect develops in a glass cage and remains under observation from the larva stage to the adult. Similarly a tank shows the process by which mosquitoes breed and the method of destroying the larva by pouring oil upon the water's surface.

It has been pointed out as a curious circumstance that a big panoramic relief map of the Panama Canal should be shown at this exposition. This map is about 50 ft. long and gives complete details and data for a clear comprehension of this undertaking. Doubtless many people have seen this who never have seen the original canal, although living fairly close by. Possibly some of these people know little of the canal itself, and they may perhaps never see it.

NEW PUBLICATIONS

THE CALLENDAR STEAM TABLES—By H. L. Callendar. Thirty-nine 5½x8½-in. pages; cloth bound. Published by Longmans, Green & Co., New York. Price, 80c.

This little book contains seven tables relating to the properties of saturated and superheated steam. In the pressure table volume and total heats are given for both Centigrade and Fahrenheit temperatures. The properties in terms of temperature are given in separate tables for values from 0 to 259 deg. C. The properties of superheated steam are similarly presented, total heat being given only in mean calories Centigrade, and volume and entropy in separate tables in terms of Centigrade degrees. The book will no doubt be useful to physicists and experimenters working with the metric system of units.

MODERN STARTING, LIGHTING AND IGNITION SYSTEMS—By Victor W. Page. Five hundred and nine 5½x8 in. pages; 295 illustrations. Published by the Norman W. Henley Publishing Co., New York City. Price, $1.50.

This book should help anyone interested in the subject to understand the important electrical features of automobiles. It is a concise and comprehensive treatise of the latest practice and is written in such a way that the reader need not be an electrical engineer in order to comprehend the text.

The book is copiously illustrated, so that the repairman can understand the construction of the systems. The following are the titles of the well written and illustrated chapters: Elementary Electricity; Battery and Coil Ignition Methods; Magneto Ignition Systems; Elementary Electric-Starter Principles; Typical Starting and Lighting Systems; Starting-System Faults and Their Systematic Location; Miscellaneous Electrical Devices.

Chapter V is of particular advantage, as every practical system is fully treated both by illustration and descriptive matter. In the following chapter the various troubles that may arise in the use of starting, lighting or ignition systems are mentioned, and the measures to be taken to remedy or avoid them are explained.

PRINCIPLES AND PRACTICE OF COST ACCOUNTING—By Frederick H. Baugh. One hundred and ninety-four 6x9-in. pages; indexed; cloth bound. F. H. Baugh, Baltimore, Md. Price, $3.

Reviewed by DEXTER S. KIMBALL*

This book, to use the words of the author, "has for its object a comprehensive and practical presentation of the general principles upon which cost accounting for manufactured articles is based, the application of these principles in a general manner to the most common types of manufacture and the illustration of the details." The table of contents is as follows: Chapter I, Synopsis of the Financial Accounting; Chapter II, Principles of Cost Accounting; Chapter III, Specific Job Cost; Chapter IV, Department Cost (Man-Hour); Chapter V, Departmental Cost (Machine- and Man-Hour); Chapter VI,

*Professor of Machine Design and Construction, Sibley College, Cornell University.

Process Cost (Simple Type); Chapter VII, Process Cost (Complex Type); Chapter VIII, Illustration of Departmental Cost Accounts; Chapter IX, Illustration of Process Cost (Simple Type).

The book differs from many others on this subject in that it is written from the viewpoint of the accountant rather than from that of the factory cost-keeper. The treatment, therefore, gives a fairly full discussion of the relation between the general-accounts and the detail-cost ledgers; in fact, it is assumed that the cost accounts are an integral part of the general accounting system. The introduction and Chapter I are mainly discussions of the principles of cost finding as usually presented and include brief arguments regarding the place and value of such items as interest, taxes, rent, depreciation, etc., which go to make up the burden, or expense. The remaining chapters give examples of the several ways in which the costs of production are found and summarized. Thus, Chapter III treats of cost finding by the production-order method, under the name of specific job cost. Other chapters treat of departmental costs and process costs, each chapter giving complete instructions as to the methods to be pursued and the books and accounts that are necessary. The discussion is largely theoretical, very few forms being presented.

The book will be of most interest to general accountants and to cost accountants who wish to study the relation of cost accounts to the general accounts. The discussion in Chapter II on the fundamentals of cost finding, while sufficient for this book, is not comprehensive enough for a beginner who wishes to obtain a clear conception of the nature of expense and the logical methods of allocating it. The brief treatment accorded many other items in other chapters might be similarly criticized so far as beginners are concerned, this briefness being so marked as sometimes to make the text a little disjointed. This is of course not so serious a matter for an experienced man, and to those who know something of accounting and cost-finding methods the book will be of service. In some respects it is written along the line of probable progress. Cost-finding methods will in all probability become more and more a factor in general accounting as the importance of cost-finding is more fully appreciated.

PERSONALS

Thomas Grant, formerly superintendent of the Hall Button Co., Jersey City, N. J., has accepted the position of mechanical superintendent with the Morgan Manufacturing Co., Newport, R. I.

Raymond Henry, until recently superintendent of the Frost Gear and Forge Co., Jackson, Mich., has become assistant works manager of the Ingalls & Shephard Forging Co., Harvey, Ill.

Isaac H. Levin, for some time past chief engineer and chemist of the International Oxygen Co. has resigned to establish a consulting practice in chemical research in Newark, N. J.

F. R. Blair, formerly secretary, treasurer and sales manager of the S. K. F. Ball Bearing Co., has resigned to organize and become president of F. R. Blair & Co., Inc., 50 Church St., New York City.

W. Wetsel, for several years associated with the Baush Machine Tool Co., Springfield, Mass., in various executive capacities, has been placed in charge of the company's recently established Detroit branch in the Dime Bank Building.

BUSINESS ITEMS

The Boos Machine Co. announces its purchase of the St. Marys Machine Works, St. Marys, Ohio. Operation of the plant is under way in the manufacture of oil and gas engines.

The Service Supply and Equipment Co., Fulton Building, Pittsburgh, Penn., has been organized by D. A. Casey as a sales agency for machinery and supplies. Mr. Casey, who will be general manager, was for the past six years machinery salesman with the Westinghouse Electric and Manufacturing Co.

The Canton Foundry and Machine Co., Canton, Ohio, contemplates the erection of a number of new buildings, including a new and much larger foundry and an annex to the machine shop, in addition to a new shop now under construction for the manufacture of its portable cranes. The additional buildings are calculated to provide about a 75 per cent. increase in manufacturing facilities.

CATALOGS WANTED

Ferdinando Bigotti, Turin, Italy, would be glade to receive catalogs and other literature from manufacturers of machine tools.

The Sheffield Machine and Tool Co., 35 S. St. Clair St., Dayton, Ohio, would like to receive catalogs from manufacturers of equipment used in making dies, jigs, fixtures, etc.

The Everett Mfg. & Supply Co., 97 Tileston St., Everett, Mass., organized to manufacture and trade in metal parts and supplies of all kinds, would be glad to receive catalogs and price lists from manufacturers of machinery and metal goods.

TRADE CATALOGS

Beaver Easy-Working Die Stocks and Square-End Pipe Cutters. The Borden Co., Warren, Ohio. Booklet. Pp. 16. 3½x6 in.

Engine Lathes, Turret Lathes, Cutting-Off Machines, Shapers, Etc. Davis Machine Tool Co., Inc., Rochester, N. Y. Pp. 40. 8x11 in. Illustrated.

The Grayson Triplex. The Grayson Tool and Manufacturing Co., Indianapolis, Ind. Bulletin. Pp. 8. 8½x11 in.

This illustrates and describes the toolroom miller and shaper built by this company.

Fine Mechanical Tools. The L. S. Starrett Co., Athol, Mass. Catalog No. 21. Pp. 336. 5x7½ in.

This contains illustraions and descriptions of the extensive line of small tools made by this company and some recent additions to the line, a new price list is included.

Sprague Electric Works, 527-531 W. 34th St., New York. Bulletin No. 48907. 500-lb. electric hoists. Illustrated, 8 pp., 8x10½ in. Bulletin No. 49600. Flexible steel armored conductors, flexible steel conduit, stamped steel boxes, fittings and tools. Illustrated, 24 pp., 8x10½ in. Bulletin No. 48706. A. C. 2- and 3-phase motors and controllers for flat-bed and small rotary printing presses. Illustrated, 12 pp., 8x10½ in.

Grinding Wheels and Machinery. Norton Co., Worcester, Mass. Catalog. Pp 162. 6x9 in. Illustrated.

In addition to a comprehensive list of the proper grades and shapes of wheels for a wide variety of work and machines this catalog contains considerable engineering data on the subject of grinding, including a table for the selection of grades, methods of mounting wheels, and rules for calculating surface and pulley speeds.

FORTHCOMING MEETINGS

American Society for Testing Materials. Annual meeting June 27 to July 1, 1916, Hotel Traymore, Atlantic City, N. J. Edgar Warburg, secretary, University of Pennsylvania, Philadelphia, Penn.

American Foundrymen's Association and American Institute of Metals. Annual meeting, September 11-16, Cleveland, Ohio, A. O. Backert, secretary, American Foundrymen's Association, Cleveland, Ohio.

American Society of Mechanical Engineers. Monthly meeting first Tuesday. Calvin W. Rice, secretary, 29 West Thirty-ninth St., New York City.

Boston Branch National Metal Trades Association. Monthly meeting on first Wednesday of each month, Young's Hotel. W. W. Poole, secretary, 40 Central St., Boston, Mass.

Providence Association of Mechanical Engineers. Monthly meeting fourth Wednesday each month. J. A. Brooks, secretary, Brown University, Providence, R. I.

New England Foundrymen's Association. Regular meeting second Wednesday of each month. Exchange Club, Boston, Mass. Fred F. Stockwell, 205 Broadway, Cambridgeport, Mass.

Engineers' Society of Western Pennsylvania. Monthly meeting third Tuesday; section meeting, first Tuesday. Elmer K. Hiles, secretary, Oliver Building, Pittsburgh, Penn.

Rochester Society of Technical Draftsmen. Monthly meeting, last Thursday. O. L. Angevine, Jr., secretary, 857 Genesee St., Rochester, N. Y.

Superintendents' and Foremen's Club of Cleveland. Monthly meeting third Saturday. Philip Frankel, secretary, 310 New England Building, Cleveland, Ohio.

Western Society of Engineers, Chicago, Ill. Regular meeting first Wednesday evening of each month, excepting July and August. J. H. Warder, secretary, 1785 Monadnock Block, Chicago, Ill.

Philadelphia Foundrymen's Association. Meetings first Wednesday of each month. Manufacturers' Club, Philadelphia, Penn. Howard Evans, secretary, Pier 45 North, Philadelphia, Penn.

Technical League of America. Regular meeting second Friday of each month. Oscar S. Teale, secretary, 35 Broadway, New York, N. Y.

Prices--Materials and Supplies

IRON AND STEEL

Pig Iron—Quotations were current as follows at the points and dates indicated:

	June 16, 1916	One Month Ago	One Year Ago
No. 2 Southern Foundry, Birmingham	$14.50	$15.00	$9.50

The Chevrolet Motor Co., 816 11th Ave., New York, N. Y. (Borough of Manhattan), plans to construct a 6-story, 200x 200-ft. automobile factory.

Bids will soon be received by Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., for furnishing and delivering at Navy Yard, New York, under Schedule 9779 forty eight ¼-in. portable electric drills and 12 electric bench grinders.

Bids will be received by Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., until June 27, for furnishing and delivering under Schedule 9787, one pipe threading machine, at Navy Yard, New York, N. Y.

Plans are being prepared by M. L. Loney, Arch., 447 West 14th St., New York, N. Y. (Borough of Manhattan), for the construction of a 6-story factory for the American Can Co. at Brooklyn, N. Y.

The Ludlum Steel Co., Watervliet, N. Y., has awarded the contract for the construction of a 1-story rolling mill. Noted Mar. 16.

Plans are being considered by the Ulster Iron Works, Dover, N. J., for the construction of an addition to its plant. John Mulligan is Vice-Pres.

Burack Bros., New York, N. Y., manufacturer of jewelry plans to establish a manufacturing plant on Beecher St., Newark, N. J.

W. H. Connolly Co., Newark, N. J., will construct a commercial garage on 12th Ave.

The Foster Engineering Co., Newark, N. J., manufacturer of valve specialties, will construct 1-story addition to its plant on Monroe St.

The J. E. Mergott Co., Newark, N. J., manufacturer of pocket book frames, has awarded the contract for the construction of a 3-story addition to its plant. L. F. Mergott, 316 Jeliff Ave., is Pres.

Plans are being prepared by William F. Lehman, Arch., for the construction of a commercial garage on Mt. Pleasant Ave., Newark, N. J., for Clarence Miller.

The Paige-Detroit Motor Car Co., Newark, N. J., will establish a garage and service station on Halsey St.

Louis Sacks, Newark, N. J., operating a foundry on Hamburg Pl., has had plans prepared for a 1-story addition.

The Splitdorf Electric Co., Newark, N. J., manufacturer of auto ignition apparatus, plans to construct a 4-story concrete addition to its plant on High St.

The Simplex Automobile Co., New Brunswick, N. J., manufacturer of automobiles, is enlarging its plant.

W. R. Phillips & Son is constructing a plant for the manufacture of iron frames for conservatories at Stillwater near Newton, N. J.

The American Motor Co., Plainfield, N. J., has awarded the contract for the construction of a plant to cost, $100,000.

The United States Metals Refining Co., Rosevelt, N. J. (Eatontown post office), will enlarge its plant. Estimated cost, $500,000.

The Lebanon Valley Iron and Steel Co., Lebanon, Penn., plans to construct a new mill at its plant at Hebron, Penn. (Lebanon post office). Estimated cost, $50,000. J. C. Brown, Gen. Mgr.

Bids will be received until June 20 by Bureau of Supplies and Accounts, Navy Department, Washington, D. C., for 3 pipe threading and cutting off machines under Schedule 9,750 for Philadelphia, Penn

The National Umbrella Frame Co., Philadelphia, Penn., will build an addition to its plant on 30th St.

The Shoop Bronze Co., Tarentum, Penn., will construct a plant for the manufacture of bronze goods. Estimated cost, $25,000.

Taylor & Wingert, manufacturer of metal stampings, plans to construct a plant at Hagerstown, Md., to cost, $100,000.

SOUTHERN STATES

Bids will soon be received by Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., for furnishing and delivering at Navy Yard, Norfolk, Va., under Schedule 9,782, 16 valve reseating machines.

Bids will soon be received by Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., for furnishing and delivering under Schedule 9,800 at Navy Yard, Charleston, S. C., 1 core drill and accessories.

Bids will soon be received by Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., for furnishing and delivering under Schedule 9,801 at Navy Yard, Charleston, S. C., one 4-in. radial drilling machine.

MIDDLE WEST

The Akron Machine and Repair Factory, Akron, Ohio, plans to construct a factory at Barberton, Ohio.

The Bucyrus Steel Co., Bucyrus, Ohio, is enlarging its plant.

The contract has been awarded for the construction of a plant for the American Sheet and Tin Plate Co., Canton, Ohio, manufacturer of hardware.

The Triumph Manufacturing Co., Cincinnati, Ohio, manufacturer of mixing machinery, plans to remodel its plant.

The American Steel and Wire Co., Western Reserve Bldg., Cleveland, Ohio, manufacturer of machinery, etc., is having plans prepared for a 1-story, 100x125-ft. addition to its plant on Aetna Rd. Estimated cost, $32,000.

Plans are being prepared by W. J. Carter, Arch., 1423 Illuminating Bldg., Cleveland, Ohio, for the construction of a factory for the American Stove Co., Cleveland. Estimated cost, $25 000. D. E. Dangler, 5017 Perkins Ave. Noted Mar. 2.

The Cleveland City Forge and Iron Co., Cleveland, Ohio, plans to construct a 1-story addition to its plant. R. A. Herman, Lakeside Ave. and East 45th St., Pres.

The McLaren Iron Works Co., 1276 East 55th St., Cleveland, Ohio, plans to construct a new factory at Urbana Rd. and Nickel Plate R.R. Estimated cost, $15,000.

Preliminary plans prepared by Mead & Hamilton, Arch., 1002 Garfield Bldg., Cleveland, Ohio, for the construction of a garage for William H. Taylor Son & Co., 630 Euclid Ave.

The Ford Motor Co., Detroit, Mich., plans to construct an assembling plant at Columbus, Ohio.

The Ohio Malleable Iron Co., Columbus, Ohio, is building an addition to its plant. Estimated cost, $60,000.

Plans are being prepared for an addition to the plant of the Defiance Screw Machine Products Co., Defiance, Ohio, manufacturer of machinery, etc.

Renick & Rice, Findlay, Ohio, plans to construct a brick and concrete garage at 124 East Main Cross St. Estimated cost, $11,000.

The Fremont Stove Co. is constructing an addition to its plant at Fremont, Ohio.

The Wasser & Zimmer Job Machine Works, Marion, Ohio, plans to establish a machine repair shop on South Main St.

The Willys-Overland Co. contemplates constructing an assembling plant at Toledo, Ohio.

Bids are being received by the Packard Electric Co., Warren, Ohio, manufacturer of machinery, for the construction of a 3-story, 64x140-ft. factory. Estimated cost, $75,000. J. W. Packard is Pres. Noted June 15.

The Briar Hill Steel Co., Youngstown, Ohio, plans to construct a benzol plant.

The Youngstown Sheet and Tube Co., Youngstown, Ohio, contemplates an expenditure of $100,000 for improving its blast furnaces at Hubbard, Ohio.

The Dockray Brass and Iron Co., Zanesville, Ohio, has awarded the contract for the construction of a 2-story addition to its plant. Noted June 15.

A factory is being constructed in Else Gundo, Calif., by the Lambert Manufacturing Co., Anderson, Ind., to be used for the manufacture of tractors.

The Lavellet Foundry Co., Anderson, Ind., is constructing an addition to its plant.

The Indiana Brass Works has awarded the contract for the construction of a 43x105-ft. melting room at Frankfort, Ind., and is in the market for equipment.

The contract has been awarded for the construction of an addition to the plant of the Oakes Co., Roosevelt Ave. and Wheeler St., Indianapolis, Ind., manufacturer of steel parts for automobiles. Estimated cost, $25,000. Noted Feb. 24.

The Studebaker Corporation, Brush and Piquette St., Detroit, Mich., manufacturer of automobiles, plans to construct a plant at Lafayette, Ind.

The contract has been awarded for the construction of a 1-story, 50x200-ft. foundry for the Laporte Furnace and Foundry Co., Laporte, Ind. Estimated cost, $8,000.

The Studebaker Corporation, Brush and Piquette St., Detroit, Mich., manufacturer of automobiles, plans to construct a plant at South Bend, Ind.

The Detroit Stove Works, Detroit, Mich., has awarded the contract for the construction of a factory at 1320-80 East Jefferson St. Estimated cost, $25,000.

The Grant Iron and Metal Co. plans to construct a plant at Detroit, Mich.

The Motor Products Corporation, 762 Woodward Ave., Detroit, Mich., manufacturer of motor cycles, etc., plans to construct a plant.

The Standard Fuel Appliance Co., 1267 Beaufair Ave., Detroit, Mich., manufacturer of furnaces for treating, hardening and carbonizing steel, is enlarging its plant.

The Studebaker Corporation, Brush and Piquette St., Detroit, Mich., manufacturer of automobiles, plans to construct a plant at Muncie, Ind.

The plant of Johnson Bros. Boiler works, Grand Haven, Mich., recently destroyed by fire with a loss of $50,000, will be rebuilt.

The American Safety Lock Co. plans to construct a plant at Grand Rapids, Mich.

The contract has been awarded for the construction of a factory at Muskegon, Mich., for the L. O. Gordon Manufacturing Co., manufacturer of cam-shafts and other motor specialties. Estimated cost, $15,000. Noted May 25 and June 1.

The Illinois Specialty Manufacturing Co., Bloomington, Ill., recently incorporated, plan to establish a factory for the manufacture of a patented banana ripener. A. L. Frankeberger, Bloomington, is interested.

Joseph M. Fitzgerald, Daniel J. Cahill and Frank M. Flynn, Chicago, Ill., have purchased a site on Emerald Ave. on which they plan to construct a garage.

The contract has been awarded for the construction of a 7-story factory at Franklin and Superior St., Chicago, Ill., to be occupied by the Lawrence Manufacturing Co., manufacturer of machinery, etc. Estimated cost, $60,000.

The Sasgen Derrick Co., 3101 Grand Ave., Chicago, Ill., will build an addition to its machine shop. Estimated cost, $18,000.

The contract has been awarded for the construction of a garage for John K. Shortall, 1664 Prairie Ave., Chicago, Ill. Estimated cost, $15,000.

Plans are being prepared for additions to the plant of the American Carbon and Battery Co., Rock Rd., East St. Louis, Ill., manufacturer of electrical supplies.

The Joseph F. Wangler Boiler and Sheet Iron Works, St. Louis, Mo., plans to establish a factory at Litchfield, Ill.

The Illinois Steel Co., Chicago, Ill., will construct an addition to its plant at South Chicago. Estimated cost, $20,000.

Hugh Agner, of the Raymond C. Agner Co., Burlington, Wis., has purchased a site on Geneva St. on which he plans to construct a 2-story, 60x150-ft. garage.

Wallace Montague, La Crosse, Wis., plans to construct a 2-story garage to be leased by the Overland Motor Car Co. Estimated cost, $50,000.

The Wisconsin Welding and Cutting Co. is constructing an addition to its plant at 315 4th St., Milwaukee, Wis.

A. Pattison, Mondovi, Wis., plans to construct a 1-story, 40x132-ft. garage and repair shop.

Plans are being prepared by Sindahl & Matheson, Arch., Neenah, Wis., for the construction of a public garage for Julius Denhardt. Estimated cost, $10,000.

The contract has been awarded for the construction of a 1-story, 65x250-ft. factory for the Perfe Radiator Co., 15th St., Racine, Wis. Estimated cost, $12,000. Noted May 25.

The Milwaukee Stamping Co., 64th and Pullen Ave., West Allis, Wis., manufacturer of hardware specialties, plans to construct a 72x122-ft. addition to its plant. Estimated cost, $15,000.

WEST OF THE MISSISSIPPI

The contract has been awarded for the construction of a garage for Leonard Everitt, 810 2nd Ave., Council Bluffs, Iowa.

Bids have been received for the construction of a 1-story machine shop and garage at Davenport, Iowa, for the Lee Broom and Duster Co. Estimated cost, $10,000.

Plans are being prepared for the construction of a 2-story factory at Marshalltown, Iowa, for Fisher Governor Co., manufacturer of steam pumps and machinery.

The Western Crucible Steel Castings Co. plans to construct additions to its plant on 29th St. between Grand and Pleasant Ave., Minneapolis, Minn. Estimated cost, $50,000.

The contract has been awarded for the construction of a 2-story garage at 3814 Farnum St., Omaha, Neb., for Thorevald Bronderslav. Estimated cost, $30,000. Noted May 11.

The American Water Heater Co., recently incorporated, plans to equip a factory for the manufacture of water heaters at St. Louis, Mo.

The C. Heinz Stove Co. plans to install new equipment at its factory at St. Louis, Mo.

The Republic Motor Truck Co., recently incorporated, plans to equip a machine shop and garage at St. Louis, Mo.

Bids have been received for the construction of a plant at Valley Park, Mo., for the Barks & Barstow Manufacturing Co., manufacturer of steel roofing and specialties. Noted June 1.

The Texas Iron and Metal Co. plans to construct a foundry at Dallas, Tex. Estimated cost, $15,000.

H. W. Hartsaw and associates, Bristow, Okla., have organized a company to construct a factory at Bristow for the manufacture of a patented lightning arrester.

L. Conway has been granted a permit for the construction of a garage at 617 South Main St., Tulsa, Okla.

WESTERN STATES

The contract has been awarded for the construction of a 2-story reinforced-concrete garage at Seattle, Wash., for the Winton Motor Car Co. Estimated cost, $65,000. Noted June 15.

M. G. Thorsen plans to construct a 2-story garage at Washington and Lownsdale St., Portland, Ore. Estimated cost, $25,000.

Bids will be received until July 11 by Bureau of Supplies and Accounts, Navy Department, Washington, D. C., for 1 set of large plate bending rolls under Schedule 9752 for Mare Island, Calif.

The Aluminum Products Co., La Grande, Ill., has awarded the contract for the construction of a factory at 2nd Ave. and East 11th St., Oakland, Calif. Noted May 25.

The contract has been awarded for the construction of a garage at Oakland, Calif., for A. Stark. Estimated cost, $20,000.

J. P. Gardner, 22 California Ave., Santa Monica, Calif., plans to construct a garage and machine shop on Ocean Ave., Santa Monica. Estimated cost, $10,000.

CANADA

Armstrong-Whitworth of Canada, Ltd., plans to construct an addition to its plant at Longueuil, Que., for the manufacture of steel tires for locomotives and passenger rolling stock. Estimated cost, $750,000. M. J. Butler is Mgr.

The Dominion Sheet Metal Co. is constructing additions to its plant on Burlington St., Hamilton, Ont. Noted May 11.

We have been advised that the Renfrew Electric Manufacturing Co., Ltd., Renfrew, Ont., is in the market for zoggle and drawing presses. Noted June 8.

Press reports state that the Canadian Sprayer Co. plans to construct a factory at Trenton, Ont., for the manufacture of sprayers and gasoline engines.

GENERAL MANUFACTURING

NEW ENGLAND STATES

The Magnet Knitting Mill has awarded the contract for the construction of a 2-story, 75x250-ft. addition to its mill at Clinton, Maine.

Burrill & Clark is constructing an addition to its weave shed at Corinna, Maine, and is in the market for machinery.

Plans are being prepared for the construction of an addition to the plant of the Home Scale Co. at Rutland, Vt.

Bids are being received for the construction of a 4-story, 65x322-ft. factory for the Boston Woven Hose and Rubber Co., Cambridge, Mass.

Fire, June 7, destroyed the plant of the Kress Carriage Co. at Lawrence, Mass.

Fire, June 11, damaged the paper plant of T. E. Chase & Son Co. on Howe St., Lowell, Mass. Loss, $8,000.

The Kinney Worsted Yarn Co., recently incorporated, plans to construct a factory at Pittsfield, Mass.

Plans are being prepared by Cutting, Carleton & Cutting, Arch., 44 Front St., Worcester, Mass., for the construction of a 4-story addition to the factory of the Graton & Knight Manufacturing Co., 344 Franklin St., Worcester, manufacturer of boots and shoes.

The International Braid Co. plans to construct a 4-story factory at its Elmwood mills at Daboll and Mawney St., Providence, R. I.

The contract has been awarded for the construction of a 4-story, 60x150-ft. mill at Norwich, Conn., for the Winchester Woolen Co. Estimated cost, $75,000. Noted June 8.

The contract has been awarded for the construction of a 83x163-ft. mill at Thomasville, Conn., for the Winchester Woolen Co. Estimated cost, $50,000. Noted Apr. 20 and May 18.

MIDDLE ATLANTIC STATES

The contract has been awarded for the construction of a 3-story factory for the Chautauqua Worsted Mills, Falconer, N. Y. Estimated cost, $45,000.

The contract has been awarded for the construction of a mill at West 2nd and Schuyler St., Oswego, N. Y., for the Hayes Knitting Co. Estimated cost, $50,000. Noted Feb. 17.

Bids are being received by the Utica Spinning Co., Utica, N. Y., for the construction of a 3-story, 50x100-ft. spinning mill. Estimated cost, $25,000. R. Hatfield, Whitesboro St., is Pres.

The Aronsohn Bloom Silk Mills, Bayonne, N. J., plans to construct a new addition to its plant at the foot of West 23rd St.

The B. F. Boyer Co., Camden, N. J., manufacturer of worsted yarns, will construct a new addition to its plant and improve and enlarge its present plant.

The Magnetic Pigment Co., manufacturer of coloring matter, Camden, N. J., will construct an addition to its plant.

Plans are being prepared for a 2-story addition to the plant of the Stumpf Leather Co., Harrison, N. J.

The American Hair Felt Co., Newark, N. J., has awarded the contract for the construction of a new plant on Lockwood St. Estimated cost, $50,000.

The Beckton Chemical Co., Newark, N. J., will construct a 1-story addition to its plant on Vanderpool St.

The Consolidated Color and Chemical Co., Brown St., Newark, N. J., will construct an addition to its plant to be used as a chemical laboratory.

E. Kaufman & Co., Newark, N. J., manufacturer of traveling bags, will construct a new factory on Murray St.

The Empire Rubber Co., Trenton, N. J., manufacturer of automobile tires and mechanical rubber goods, will build a 2-story addition to its plant on North Clinton Ave.

The American Bronze Powder Manufacturing Co., Verona, N. J., will build an addition to its plant on Grove St.

Plans are being prepared for a bleaching plant at Covington, Penn., for the West Virginia Pulp and Paper Co., 200 5th Ave., New York, N. Y.

The Rosell Silk Mill Co., Hazleton, Penn., will construct a large addition to its plant on McKinley Ave.

Fire recently damaged the factory of the William Wolstencroft Felt Manufacturing Co., Mulberry and Bridge St., Frankford, Philadelphia, Penn. Loss, $10,000.

J. D. Arthur and A. Donald, Philadelphia, Penn., have purchased a site at Monmouth, Janney and Weikel St. on which they plant to construct a factory for the manufacture of shoes.

SOUTHERN STATES

The Charles Boldt Glass Co., Huntington, W. Va., plans to construct an addition to its plant in West Hamilton. Estimated cost, $7,500.

The Reaugh Chemical Co., Wheeling, W. Va., recently incorporated with $250,000 capital stock, plans to equip a plant for the manufacture of chemical dyes.

The G. H. Y. Hosiery Co., Concord, N. C., recently incorporated with $100,000 capital stock, plans to construct a hosiery mill at Concord. A. J. York is interested.

The Magnet Knitting Mills, Clinton, Tenn., has awarded the contract for the construction of a 2-story factory. Estimated cost, $100,000. Noted Apr. 27.

The Tennessee Mills, Knoxville, Tenn., recently incorporated with $100,000 capital stock, plans to construct a factory for the manufacture of knit underwear. Estimated cost, $30,000. L. D. Tyson, Pres.

The contract has been awarded for the construction of a plant for the Buckeye Cotton Oil Co., Memphis, Tenn. Estimated cost, $100,000. Noted June 15.

MIDDLE WEST

The Punctureless Auto Tire Co., Akron, Ohio, plans to construct a factory at Barberton, Ohio.

The Federal Foundry Supply Co., 2639 East 79th St., Cleveland, Ohio, manufacturer of foundry flour, etc., plans to construct a 2-story addition to its plant. Estimated cost, $25,000.

The Fitzsimons Co., Youngstown, Ohio, manufacturer of shafting, plans to construct a factory on Wilson Ave. Estimated cost, $5,760.

The Armour Packing Co., Indianapolis, Ind., plans to remodel its plant at Ray and Cody Ave. Estimated cost, $20,000.

The contract has been awarded for the construction of a 1-story chemical building for the Eli Lilly Co., Indianapolis, Ind., manufacturer of chemicals. C. J. Lynn, 224 East McCarty St., Secy.

The Solvay Process Co., manufacturer of chemicals, Jefferson Ave., Detroit, Mich., plans to construct an addition to its plant. Estimated cost, $36,000.

Fire recently destroyed a portion of the plant of the Valley City Chair Co., Grand Rapids, Mich. Loss, $150,000.

Oliver M. Burton Co., 2024 South Racine Ave., Chicago, Ill., plans to construct a factory for the manufacture of cotton felt hats.

The Dixie Cotton Felt Mattress Co., 2024 South Ravine Ave., Chicago, Ill., plans to construct a factory.

The Great Western Smelting and Refining Co., Chicago, Ill., will construct a 1-story foundry at 600-28 41st St. Estimated cost, $50,000.

The Haysen Manufacturing Co., 13th St. and St. Clair Ave., Sheboygan, Wis., plans to construct a plant for the manufacture of breat wrappers.

We have been informed that the West Bend Woolen Mills, West Bend, Wis., will be in the market for looms, spindles and gages for the new additions which it plans to construct to its factory. Address John Geib, West Bend. Noted Mar. 23 and June 1.

WEST OF THE MISSISSIPPI

The Studebaker Automobile Corporation, Brush and Piquette St., Detroit, Mich., plans to construct a plant at St. Paul, Minn., for the manufacture of tires.

The Kaut-Reith Shoe Co. plans to construct an addition to its plant at Carthage, Mo.

The Allen Mop Co., recently incorporated, plans to equip a factory at Kansas City, Mo., for the manufacture of mops.

The National Security Envelope Co. plans to build factory at Kansas City.

Fire, June 1 destroyed the plant of the Seymour Compress and Ice Co. at Seymour, Tex. Loss, $60,000.

The Tulsa Packing Co. plans to construct a cold-storage plant at Tulsa, Okla. Estimated cost, $65,000.

The Peoples Gin Co. plans to construct a cotton gin at Bristol, Colo. Estimated cost, $8,000.

WESTERN STATES

The Altoona Packing Co. has purchased a site at Astoria, Ore., and plans to construct a cold storage plant.

The Portland Woolen Co. has been granted a permit for the construction of a 2-story addition to its factory at St. Johns, Ore. Estimated cost, $6,500.

The Fresno Fruit Growers plan to construct a packing house at Tulare and 2nd St., Fresno, Calif. Estimated cost, $4,000.

The Benchley Fruit Co. plans to rebuild its plant at Fullerton, Calif., which was recently destroyed by fire with a loss of $35,000. William Benchley is Mgr.

Gilbert F. Stevenson plans to construct a 100x100-ft. addition to its packing plant at Woodlake, Calif.

CANADA

The Royal Paper Box Co. plans to construct a factory at Brantford, Ont. Estimated cost, $12,000.

The Colonial Knitting Co. plans to construct a factory at Elmira, Ont., and install machinery. Estimated cost, $25,000.

The citizens of Simcoe, Ont., voted to loan the Unique Shoe Co. $20,000 for the construction of a factory.

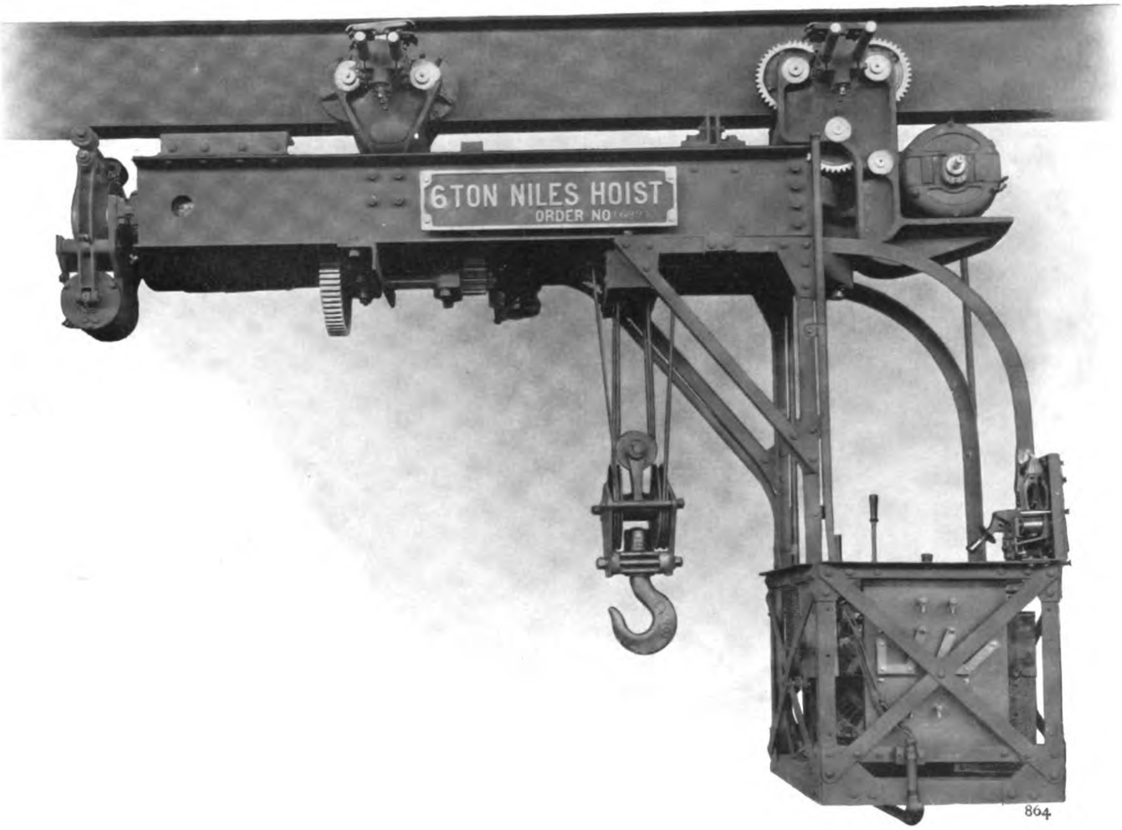
Mono-Rail Trolley Hoist

Load carried from one point to any other by transfer bridge and I-beam tracks



THE single I-beam track on which the trolley runs can be arranged in an almost endless variety of ways; spur tracks can be run out at intervals over the gallery floor; a track may be curved around to run lengthwise of the gallery floor; tracks may be run off to the various buildings of an extensive plant; tracks may be run either across or lengthwise of railway sidings, for the unloading of cars. The cage for the operator is attached to the trolley so that he is always with the load.

Write for our 90-page Catalog "Niles Electric Traveling Cranes" showing various uses to which the above trolley is being applied.

The United States Supreme Court Says

"An article alone is not necessarily the inducement and compensation for its purchase. It is in the use to which it may be put, the purpose it may serve and *there is deception and fraud when the article is not of the character or kind represented and hence does not serve the purpose.*"

SO RARELY does the Supreme Court of the United States deliver an opinion dealing directly with advertising ethics that there will be special interest in the decision handed down April 24, wherein the highest court in the land is placed on record as opposed to undue exaggeration in advertising. In view of current activities of the Post Office Department, the Federal Trade Commission, etc., this expression from the Supreme Court may be accounted particularly timely since it deals specifically with dishonest advertising.

In effect, the Supreme Court says that an advertiser is dishonest when he raises false expectations on the part of a customer. Mere exaggeration of the qualities possessed by an article might be condoned, although the court does not expressly say so, but when an advertiser goes farther and invents advantages for his article or assigns to it virtues it does not possess he is distinctly beyond the pale.

Special Shop Methods Used in Making Multigraphs

By Fred H. Colvin

SYNOPSIS—The making of the Multigraph involves the use of special milling and drilling methods. A rotary staking device is of interest. Machines are made as convenient as possible. Special testing fixtures of somewhat unusual design suggest applications of similar fixtures to other classes of work.

The making by the American Multigraph Co., Cleveland, Ohio, of the Gammeter Multigraph, that form of condensed printing office for all sorts of commercial letters and similar work, involves the use of many interesting fixtures and methods.

The type segment, which forms half of the printing cylinder, is made from an aluminum casting well braced on the interior, as can be seen in Fig. 1. Here, two of these segments are held together in a fixture, being first surfaced on the flat sides and then clamped into a complete cylinder by means of the ears *AA*.

The fixture locates them in line with the spindles of the two heads mounted on the one lathe, and in this position the end is bored out to receive the end plate of the printing cylinder. The boring tools are carried on the spindle nose, and the lathe carriage is moved first in one direction and then the other. The stops *B* locate the depth of the counterbore at each end. The segments then have the ears cut off and go next to a gear cutter, which cuts the slots for the steel rails that are afterward inserted. The gear cutter also surfaces the outside of the segment, saving the operation of turning. One of the holding mandrels is shown at *C*, Fig. 1.

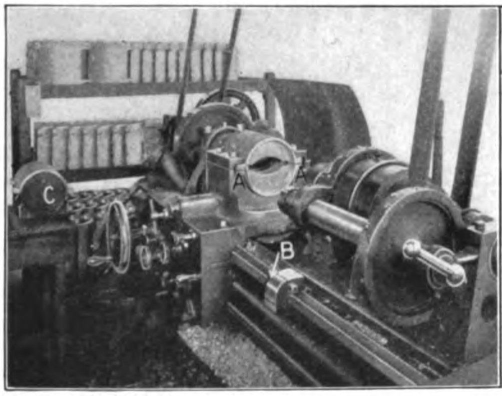

FIG. 1. BORING ENDS OF TYPE SEGMENTS

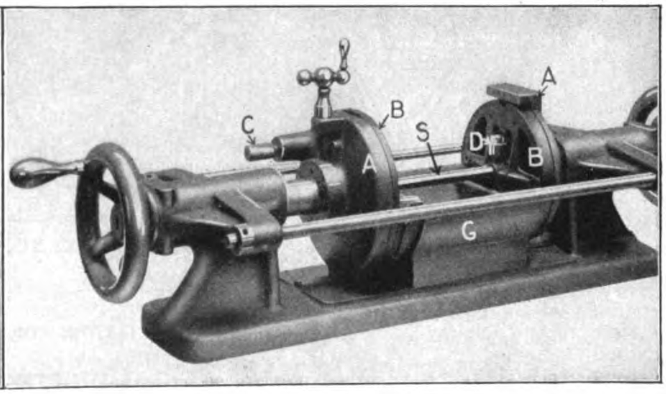

FIG. 2. FIXTURE FOR ASSEMBLING HEADS AND SEGMENTS

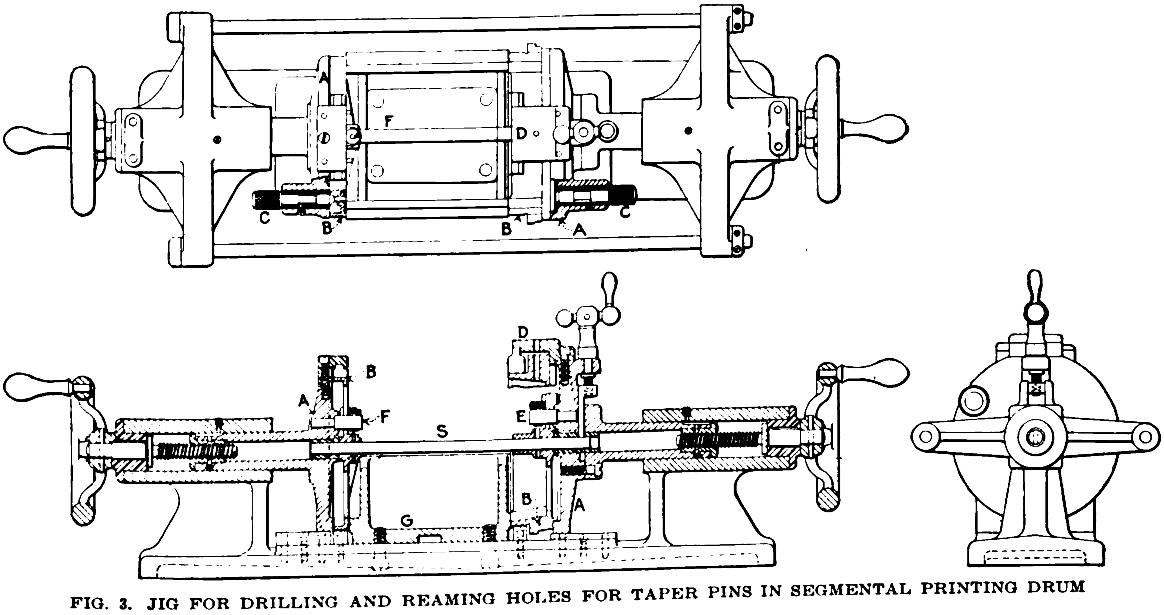

FIG. 3. JIG FOR DRILLING AND REAMING HOLES FOR TAPER PINS IN SEGMENTAL PRINTING DRUM

After the slots are milled, the I-shaped steel rails are put into place and the segments placed in a special fixture mounted on a shaper, as shown in Fig. 5. The ram carries a roll that might be called a rotary staking tool, shown at *A*. It is toothed in the center portion, which runs between the rails and forces the metal down around the lower head of the I-shaped section. The roll is grooved each side of the toothed portion, so as to hold the rails in position and assist in the staking operation.

The indexing arrangement is operated by the stop *B*, the lever *C*, which indexes the drum *E* by means of the latch *D*, operating the double pawls shown below. This operates very satisfactorily, both as to accuracy and rapidity.

Fig. 2 shows the way in which the segments are fitted to the heads of the printing cylinder. The end plates *A* force the two heads *B* into proper relation, the indexing pin *C* holding against rotation, while the locating hole is drilled through the bushing *D*.

The details of this drilling and reaming fixture are shown in Fig. 3, parts being lettered to correspond with Fig. 2. This shows very clearly how the heads *BD* of the printing drum fit into proper position on the shaft *F*. The heads are pressed in until they touch the central stop *G*. Then the holes are drilled and reamed, the jig plate *D* guiding the drill for the outer hole and the bushing *E* for the hole through the shaft. The bushing *F* performs a similar duty at the other end. Index pins *C* locate the heads with relation to each other, so as to be in line when pinned to the shaft.

Another interesting fixture—for milling the center plates—is shown in Fig. 4. The plate *A* is centered over the stud *B* and is held in position by the spider *C*, which carries four hardened-steel points. The spider is also centered on the stud *D* and is fastened by means of the hinged open washer *D* in connection with the setscrew shown. The center plate is indexed in its different positions by the ring pin *E*, located in the hardened bushing *F*. The side location of the plate to be milled is controlled by the screw *H* and the adjustable screw *G*.

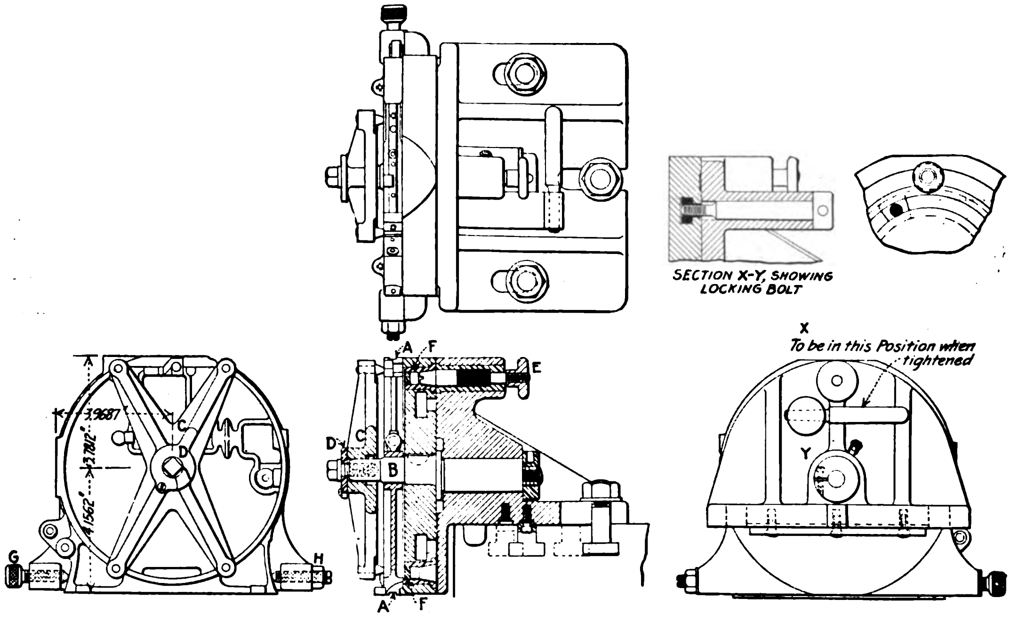

FIG. 4. MILLING FIXTURE FOR CENTER PLATES

Another feature of the Multigraph is the movable cam bands, which act in a similar manner to the throw-off on a rotary printing press. These bands are cut from Shelby steel tubes, as in Fig. 6, a special mandrel being used for this purpose, after the rings have been bored to insure the correct internal diameter. They are cut off by the special tool shown, in a standard engine lathe that is kept for this particular work. It will be noticed that

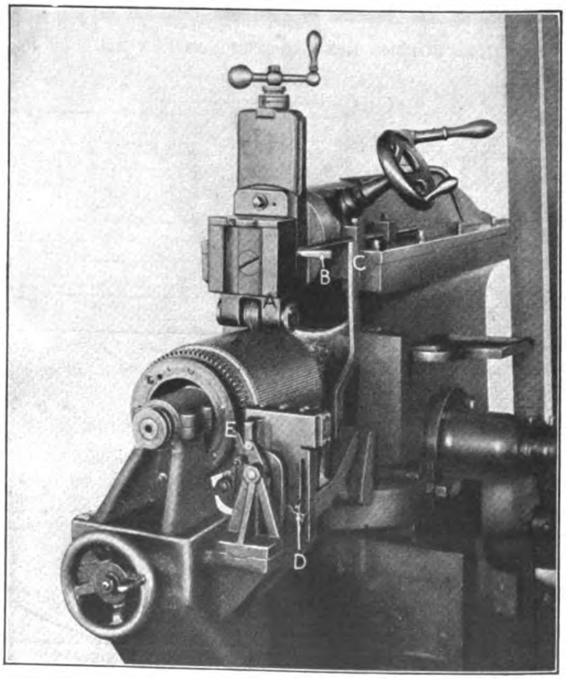

FIG. 5. ROLLING IN THE TYPE RAILS

a hole is drilled at one end of the blank, as at *A*, for driving during the turning and cutting operations. This takes the driving stress off the mandrel and avoids the necessity of gripping the tube, with the danger of springing it.

Cams are milled on this ring by special fixtures, after which it is graduated, as shown in the foreground of Fig. 7. These graduations are made in a punch press with the dies shown. The cam ring fits inside the lower

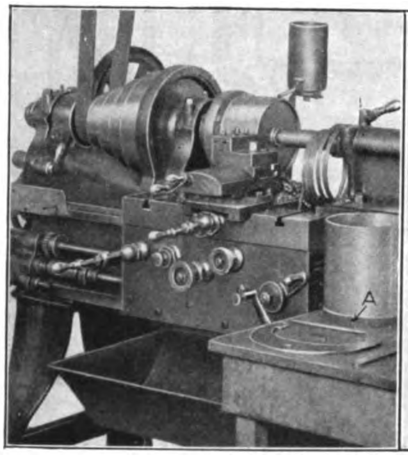

FIG. 6. CUTTING OFF CAM BANDS

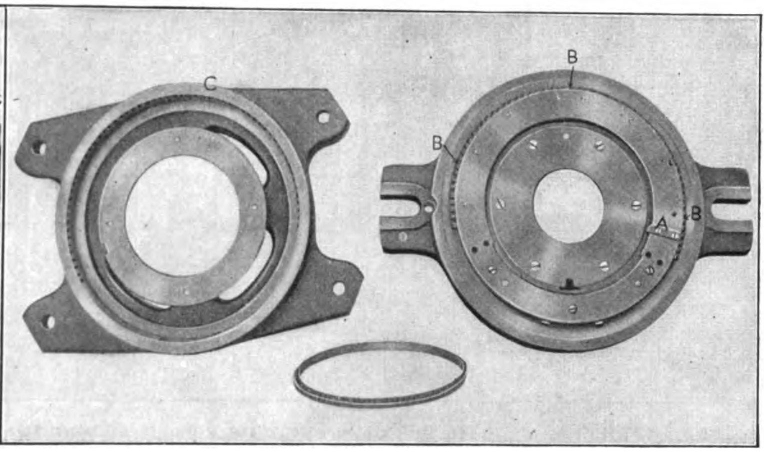

FIG. 7. RADIAL GRADUATING FIXTURE

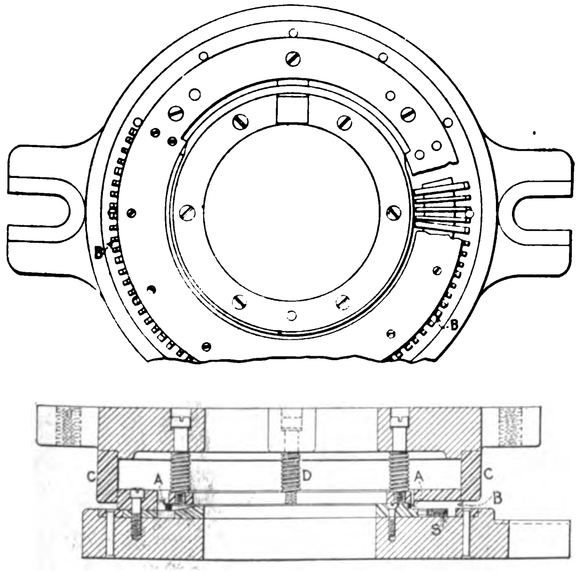

FIG. 8. DETAILS OF GRADUATING DEVICE

die at the right, being located by the finger *A*. The punches, about 60 in number, are shown radially around the die, as at *B*. The left-hand portion bolts to the ram of the press, the outer ring *C* being beveled on the inside to match the outer end of the punches *B*. When the ram descends, this beveled surface comes in contact with the outer end of the punches and forces them all in radially, each punch making its graduation at the proper position on the ring. This method of graduating makes it easy to renew one or more punches independently of all the rest and can probably be adapted for other uses without difficulty.

Details of this graduating device can be seen in Fig. 8, the lower view showing the two parts assembled and ready for operation. This shows the beveled ring *C* ready to force one of the punches *B* into contact with the ring *A*, which is held down in position by the springs *D*. Each punch has a downward projection that acts against the spring *S* and is returned by it as the ring rises.

Fitting the drilling machines to accommodate the work they are to do is not usually performed in the manner shown in Figs. 9 and 10. Here a single- and a double-spindle drilling machine are grouped together and supplied with a common table so as to afford a level platform for moving the drilling fixtures from one to the other. The machine at the left has been raised by the filling block *A*, so that the distance between the spindle and the table has been greatly increased over its original capacity. The first spindle of the next machine has been raised by the block *B*, the third spindle remaining in its original position.

The object of doing this will be clearly seen by a little study of Figs. 9 and 10, which show the great convenience of being able to turn the drilling fixture in any desired position and to have a spindle to accommodate the varying heights, as shown. Fig. 10 illustrates the fixture on end and also the methods of quickly changing tools for the various operations. It will be noticed here that the second spindle is equipped with a tapping chuck and also that the two machines are connected by the shaft *D*.

Three interesting testing fixtures are illustrated in Figs. 11, 12 and 13. The first is to indicate the squareness or levelness of the long base plate, the method of handling this being clearly shown and requiring no particular explanation. The four feet at the corners rest on the lower part of the testing fixtures, while the arms at each end carry indicating buttons to test the upper surfaces.

The fixture seen in Fig. 12 is somewhat unusual. It tests the end casting shown at the right, the center hole slipping over the plug *A* and a turned surface on the inside resting on the three raised points *B*, while the studs *C* form a gage for the lower edge of the casting, to insure its being in the correct position for gaging.

Plungers *D* and *E* actuate the multiplying levers *F* and *G* and so indicate very minute variations in the

squareness of the surfaces being tested. This is a particularly sensitive instrument and one which has been found very useful in this general class of work. by the finger *A* acting on the multiplying lever, the point of which may be seen at *B*. A slight variation shows very plainly with the larger graduations at the top.

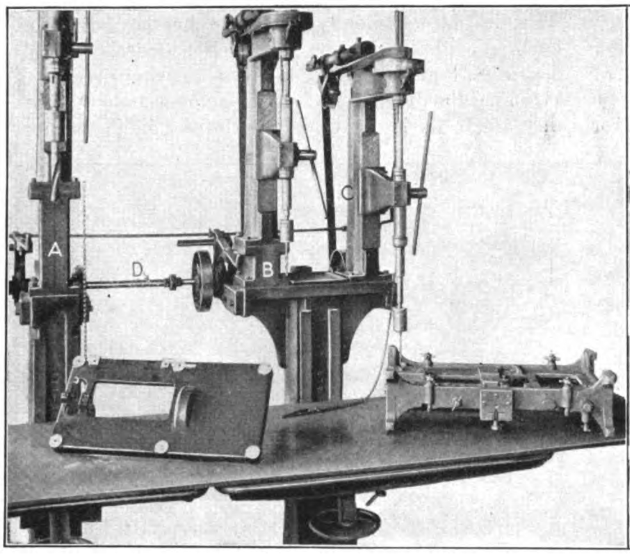

FIG. 9. DRILLING MACHINE SPINDLES BUILT UP FOR DIFFERENT HEIGHTS OF WORK

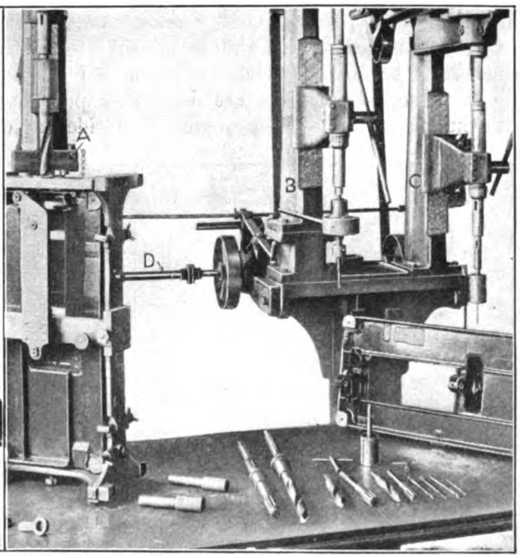

FIG. 10. USING THE DIFFERENT SPINDLES AND TOOLS FOR VARIOUS OPERATIONS

It is important that the end of the drum carrying the type segment be perfectly square with the shaft on which it revolves. In order to be sure that this is the case, the device illustrated in Fig. 13 has been constructed to test this part of the machine. The drum with the two heads in place is mounted vertically between centers, as shown, and the truth of the inside surface of the head is measured

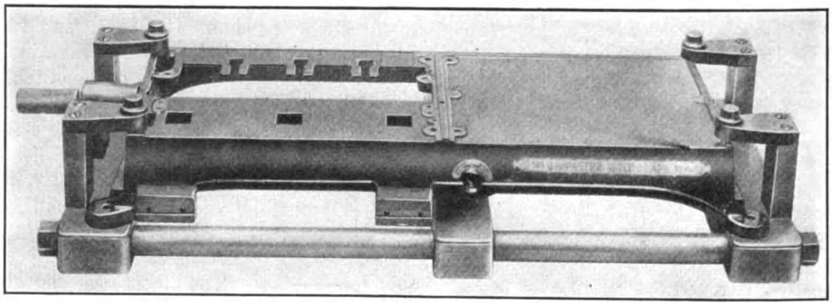

FIG. 11. TESTING SQUARENESS OF LONG BASE PLATE

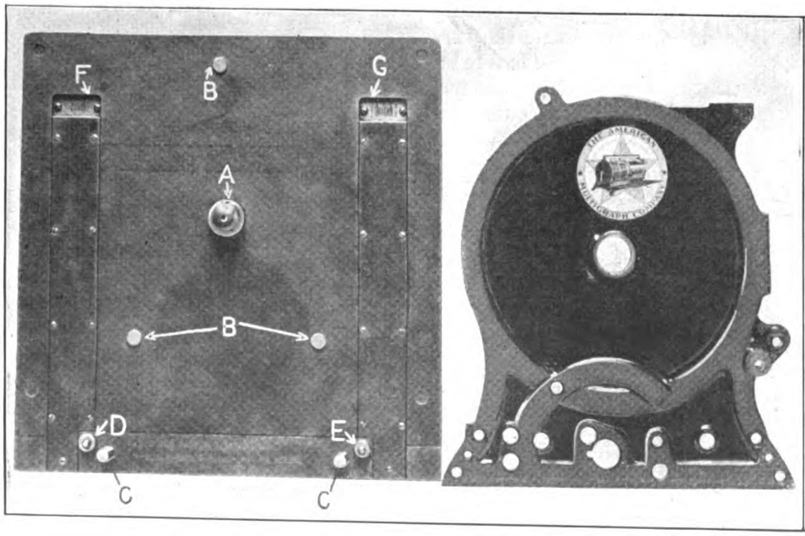

FIG. 12. DOUBLE INDICATING FIXTURE FOR SURFACE OF END PLATE WITH LOCATING AND GAGING STUDS

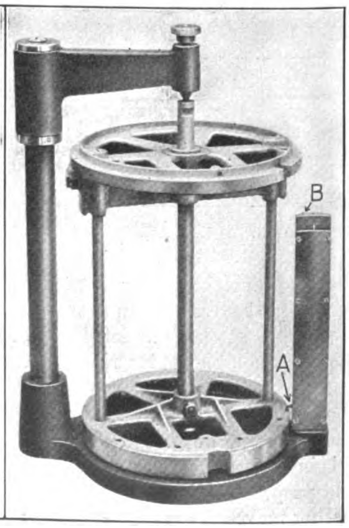

FIG. 13. TESTING SQUARENESS OF HEAD WITH SPINDLE

Small dogs, or chasers, Fig. 14, are used for holding the type in position between the rails on the segment previously shown. These dogs are made from rods of specially drawn steel bar of such a section as will slip between the upper heads of the I-rails, which have been previously staked into position in the segment. The machine shown in Fig. 15 is for cutting off these dogs and at the same time milling a notch in them for receiving the spring that prevents them from sliding too freely between the rails. The specially formed bar is seen feeding in at *A*, the feeding mechanism being shown at *B*, the cutting-off saw at *C* and the specially formed cutter at *D*.

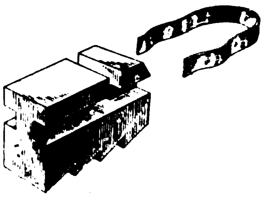

FIG. 14. CHASER BLOCK AND SPRING

The springs are put on these little dogs by an ingenious hand machine, Fig. 16. The spring wire comes in spools; it is about 0.08 in. wide and 0.01 in. thick. This feeds down from the spool, as shown at *A*, while the dogs that are to have the springs put on them are placed in the magazine *B*. The lever and its connections *DC* are so arranged that a throw to the left cuts off a sufficient length of the flat spring wire and forms it around the sides of the dog, the wire itself feeding through a slot milled especially for this purpose. This can be done very rapidly, as the parts are small and the girls become expert at this kind of work after a little experience.

Fig. 17 shows a little device for cutting off small rubber stops that are sometimes used at the ends of the line. These rubbers come in long strips, which are fed by gravity through the side tubes shown on the upright at *A*. Suitable knives arranged at *B* and operated by the lever *C* cut off these rubber plugs at a very rapid rate, allowing them to fall into the box *D*.

A different sort of cutter, Fig. 18, is for stripping the insulation from double wires used in connection with the motor on the Multigraph outfit. This is not only quicker than the old pen-knife method, but also avoids injury to the wires, at the same time leaving them quite clean of insulation. At *A* are upright knives with a stop behind them at the proper distance for the stripping of the insulation. The wire with its covering is forced down between these knives so that the end rests against the stop at the back. Then the lever *B* is moved, which clamps the wires by their insulation and also pulls them toward the operator, drawing the wire out of its insulation and leaving it clean, as can be seen at *C*.

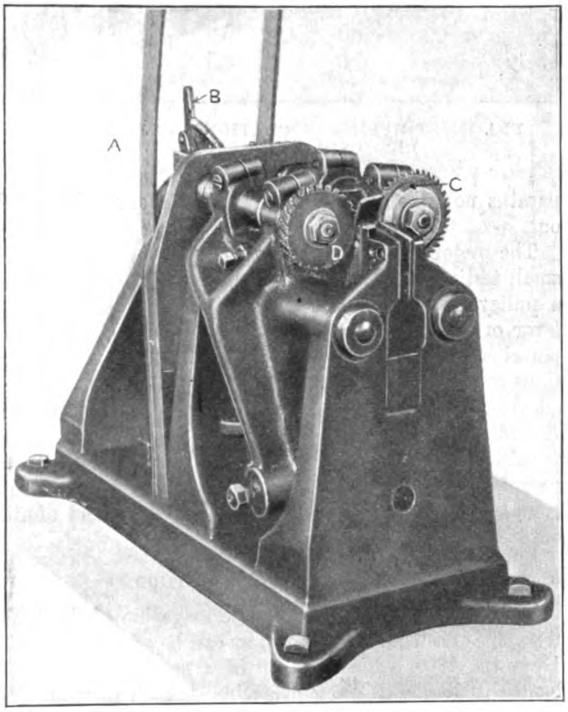

FIG. 15. SPECIAL MILLER FOR SLOTTING CHASER BLOCKS

FIG. 16. PUTTING BANDS ON CHASER BLOCKS

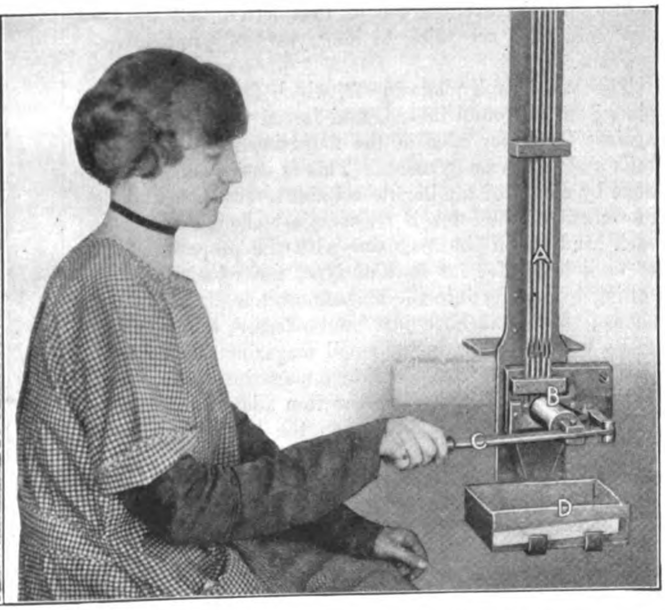

FIG. 17. CUTTING OFF RUBBER STRIPS

In order to make sure that the motor supplied with the Multigraph can deliver the power required, each motor is tested, as shown in Fig. 19. This is a crude arrangement, which will give way to a more complete apparatus now that the device has been thoroughly tested out.

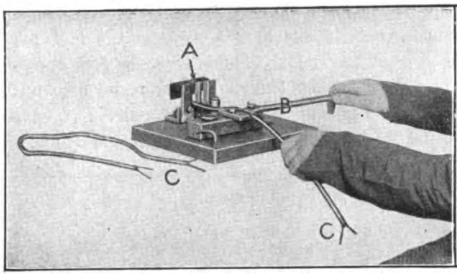

FIG. 18. STRIPPING INSULATION FROM ELECTRIC WIRES

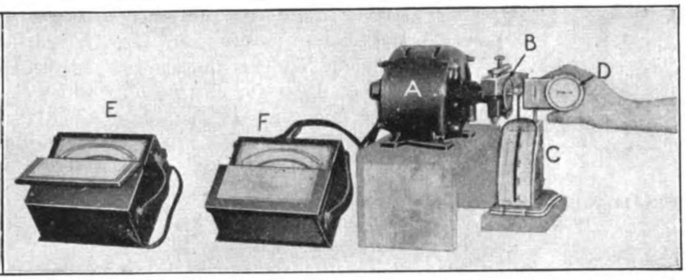

FIG. 19. SIMPLE METHOD OF TESTING MOTORS USED ON MULTIGRAPHS

The motor *A* is mounted on the raised portion of the small testing stand, and the prony brake *B* is applied to a pulley fastened on the end of the motor shaft. The lever of this brake bears on the platform of the small postal scale *C*, while the tachometer *D* shows the revolutions of the armature shaft. At the same time the electrical readings are taken from the wattmeter and voltmeter *E* and *F*, so that all necessary data are easily obtained for finding the exact performance of each motor. This record is kept for each machine and motor, so that any complaint or inquiry in regard to the power end of the outfit can be easily taken care of.

Magazine-Loading Method

The method of loading the type magazine of the Multigraph is decidedly ingenious, as can be seen in Fig. 20. Here the type, which is cast in a special machine, is loaded in the long filling magazine *A*, each row containing a different letter. As in all printing establishments, however, the number of letters in the font varies according to the average use of that letter, "E" always predominating, according to long years of printing experience.

The Multigraph magazine *B*, which is to be filled, is placed on the round table *C* and forced up into position against the lower edge of the magazine *A*, so that the rails and slots exactly mesh. This is easily and quickly done by means of the handwheel and screw *D*. A single movement of the lever *E* releases just enough letters of each kind to fill the magazine with the proper number of each letter for its font of type, the released letters falling by gravity into the magazine below, as at *B*. As shown, the letters have just been released, and one can easily trace the type in the small magazine by its corresponding absence from the larger magazine above. Moving the lever *D* in the other direction allows all the type in the main magazine to fall to the bottom, so as to present a uniform body at the lower end.

The next movement of the lever throws out small separating fingers or wedges, which automatically force themselves between the type in the main magazine at the proper distance to allow a sufficient number to fall into the small magazine, effectually holding in place all those above until the lever is again moved and the type falls to the bottom, ready for the next filling operation. This saves an immense amount of time and insures an accurate count of type in the lower magazine in each case. The fixtures and methods shown will give some idea of the careful attention that has been given to the problem of accurate and economic manufacturing by the American Multigraph Co., Cleveland, Ohio. A great deal of the work falls well within that rather vague limit which bounds the confines of the manufacture of precision-machine parts.

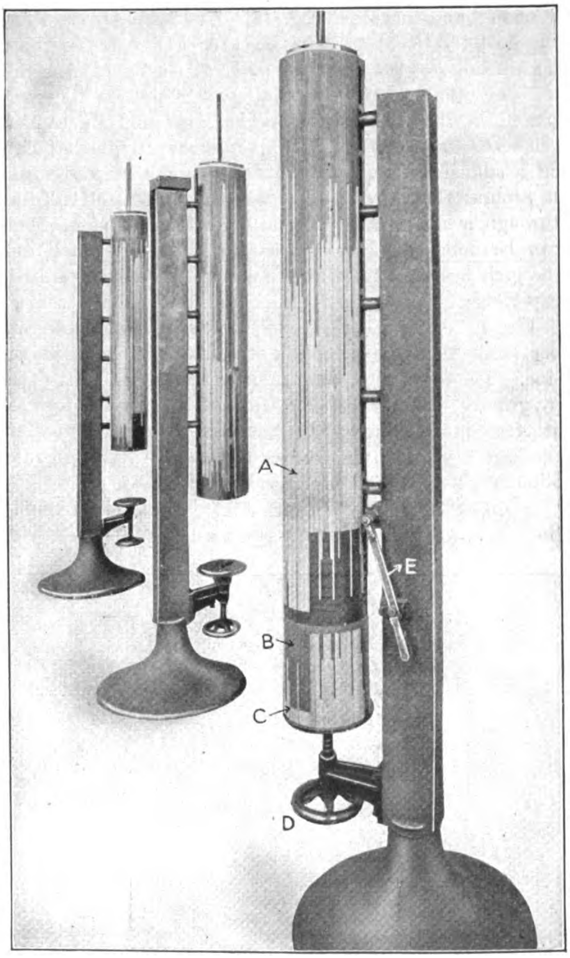

FIG. 20. SIMPLY OPERATED MAGAZINES FOR LOADING THE TYPE SEGMENTS

The Applicant's Difficulty*

By R. Fleming

It may be inferred that the writer of a letter making application for a position will express himself at his best. An analysis of 493 letters written during the years 1914 and 1915, applying for engineering positions, gives some interesting results. Of these letters 217 were from college men, either graduates or members of graduating classes. Fifty colleges were represented. Only about one letter in three from these college men could be called "good," and hardly one in twenty would receive special attention. In fact, the applications of two men stating "I am not a college man" and some letters from boys wanting to be tracers made a more favorable impression than those from the majority of college graduates.

What are some faults in their letters? In the first place, 95 out of the 217 were on notepaper. A favorite-sized page was 5x6 in. There is a semblance of authority for the use of notepaper in at least one handbook, but the advice of a professor to his senior class might well be followed:

> When you write a letter applying for a position, use business paper and not love-letter stationery, for a business letter is not a love letter.

Notepaper is inconvenient for filing. What engineer has not had personal experience with applications "filed for future reference"?

Careless handwriting is another common fault. Fine penmanship is not vouchsafed to many, but the writing of everyone can be at least legible. A consulting engineer writes in such a slovenly manner that his letter is hard to read. He may have thought that his letterhead would do away with the necessity of writing distinctly. It is often difficult to read the name at the end of a letter. An associate professor of drawing wants a salary of $40 a week, but one can only guess his name. The same is true of a candidate "for a responsible position."

A graduate of an institution like . . . should not be a "beginer," nor should a graduate of . . . be "thankfull." Perhaps the man who writes "weather," "imaterial" and "having had ample technical education to warrant a drauftsman's position" is not a college graduate.

Many applications give too little definite information. Such statements as "I am a college man," "I am a graduate from an engineering school," "have a fine technical education, being a college graduate," "am technically educated," could be better expressed by giving the name of the college and the year of graduation.

Serious Faults of Style

A flippant tone in a letter is not conducive to its favorable reception. One man writes:

> However, it is not my intention in submitting same, that it be placed on file for some future manager to cast into the wicker morgue, because sir I graduate from the Civil Engineering Course of . . . the coming June, and the position for which I am making application can be filled at that time.

A bombastic or too confident tone is not to be commended. The man who writes:

> Have had 13 years' experience in structural drafting. . . . Have never made an expensive error in any work I have turned out. . . .

may never have had much responsibility thrown upon him.

The following letter is unclassified:

> I am a young man (19). I have received a 4 year Civil Engineering Education and a year of Field Experience I am fully versed in designing and constructing steel structures, Reinforced Concrete, also numerous other things in the Engineering line.

An irreverent hand had written in pencil, "Some boy!"

Sypherd, in his "Handbook of English for Engineers," summarizes weak points in letters of application under: Poor Beginning, Faulty Sentence Structure, Excessive Use of the First Person, Excessive Modesty and Miscellaneous Errors. He gives the advice:

> Begin at once without any preliminary explanation with a statement of what you desire; say briefly, straightforwardly and without assuming too great knowledge or skill, whatever you think your future employer ought to know about what you have done or can do; refer him to men who can speak definitely and without reservations as to your ability and moral worth; then stop.

It should be noticed that no letter of application, however well written, will secure a position unless there is one to be had. For the last two or three years the bread line of engineers has been a long one. That the supply still exceeds the demand becomes evident by comparing the "Positions Wanted" with the "Positions Vacant" in the advertising columns of the technical papers. There are applicants by the score for every position vacant. The importance of the letter of application is apparent. This, however, is but one phase of a larger subject—the use of better English by engineers.

Schools Trying To Meet the Difficulty

In his preliminary analysis[1] of the replies received from 23,000 circular letters to engineers regarding the needs of the profession Professor Mann, of the Carnegie Foundation for the Advancement of Teaching, writes:

> In questioning the efficiency of the engineering schools at the present time there are four conspicuous things in which the professional men show a fair degree of unanimity. The first and most important is English. A large majority of the letters received mention the absolute necessity for higher efficiency in the training in English.

Some colleges are trying to meet this need. The Stevens Institute of Technology in its catalog for 1916-17 states: "No effort is spared to impress upon the students that their success as engineers will depend largely upon their knowledge and use of language." Attention is given to English and Logic throughout the college course. This seems more rational than to neglect them, claiming that these particular branches belong to the grammar and high schools. Where English is neglected because the course is already overcrowded with other subjects, something might be done by way of substitution. Often out-of-term and supplemental-reading courses could profitably be introduced.

In conclusion attention is called to the following books on the subject:

"Handbook of Composition," Wooley.

"Handbook of English for Engineers," Sypherd.

"The Theory and Practice of Technical Writing," Earle, and "Good Engineering Literature," Frost, are of value to the engineer given to writing for the technical press.

Jig for Lapping Special Precision Gages

By E. V. Allen

The Grayson Tool and Manufacturing Co., Indianapolis, Ind., which makes all kinds of fine tools and gages, recently had an order for a number of special comb gages. These gages had 29 teeth, or 30 spaces, the center to center distances of the teeth being 0.125 in., with the spaces, 0.0675 in. in width. Only an over-all limit of 0.0002 in. was allowable. The gages were machined and the teeth milled. They were next ground all over with enough left between the teeth for final lapping. This was done in the jig illustrated in Fig. 1. One of the comb gages is shown at *A* and another at *B*. The latter has a test piece *C* in place between the teeth. Two of these test pieces were used, and they were first carefully ground and lapped to exact size.

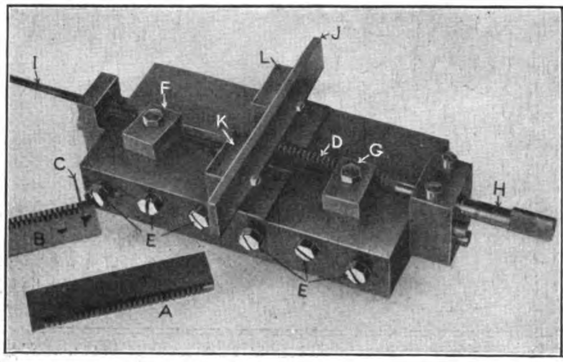

FIG. 1. GRINDING JIG FOR COMB GAGES

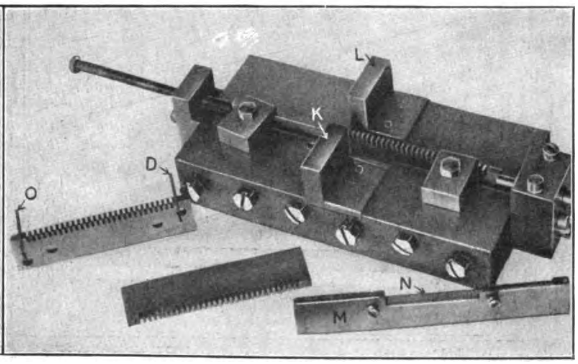

FIG. 2. LAPPING JIG FOR COMB GAGES

The gage to be lapped was placed in the slot of the jig at *D*, all side movement being carefully taken up by the adjusting screws *E*. Two clamps *F* and *G* held the work firmly to the bottom of the slot. Spacing was determined by means of the micrometer head *H*, against which one end of the gage was butted. Firm contact with the micrometer end was obtained by carefully adjusting the screw *I*. The lapping was done with a diamond lap carried in the holder *J*, which was guided by the two blocks *K* and *L*.

This will be better understood by reference to Fig. 2. Here the holder is shown at *M* and the diamond-charged lap at *N*. It will be seen that the guiding blocks *K* and *L* are made so as to afford sliding contact for the holder on both the bottom and one side. These blocks are set into the jig body and are doweled and screwed into place. With the gage set in place, the teeth are first all lapped on one side enough to clean up properly. The gage is then reversed and the other sides of the teeth lapped enough to admit the test pieces. By placing the two test pieces, as shown, at *O* and *D*, or in intermediate positions, the pieces may not only be used as individual test pieces for each space or slot, but they may be checked up with an outside micrometer.

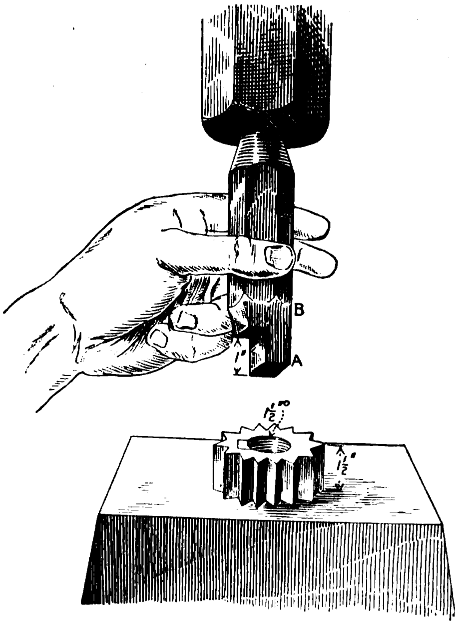
Of course, in work of this kind great care and patience must be exercised, and all tendency to accumulative error must be avoided. However, the main idea of the method of using a jig of this sort will be grasped at once and give an idea of the fine work done in this shop.

Tool for Marking Keyways in Ratchet Wheels

By Thomas Underwood

I recently had to cut keyseats in 100 ratchet wheels, as shown in the accompanying illustration. These had to be cut on a shaper; and in order to lay the keyways off easily, I made the tool shown.

The front portion *A* was curved to suit the bore of the ratchet wheels, while the part *B* was filed to the size of the keyway desired. The face of this offset was relieved in the center, and the whole point was hardened. By placing the front part *A* through the hole in the gear until *B* rested on the face and then striking the end of the tool with a fairly heavy hammer, the notch *B* left an impression on the face of the ratchet wheel of exactly the size desired for the keyway.



TOOL FOR MARKING KEYWAY

This method saves considerable time in laying off and might perhaps be used in other instances to advantage.

Improvement of the Lubricating System Increases Production

By Ethan Viall

SYNOPSIS—This article calls attention to the frequent loss of shop efficiency through improper methods of handling oil or soap-water mixtures. When handled correctly, not only is the increase in production notable, but the appearance of the shop is greatly improved.

The ordinary idea in using oil or soap water as a lubricant or coolant seems to be that, as long as the liquid is poured on the work in more or less sufficient quantities, it makes little difference how much slops over on the floor, drains from the work or accumulates in any convenient hollow or cavity. The inevitable result is a slippery, sloppy, smelly place that is not conducive to safety, efficiency or comfort. In first placing the machines in its plant the Boss Nut Co., Chicago, followed the plan of using a gravity feeding tank for each machine. The machines are a battery of 2- to 20-ton punch presses and a battery of an equal number of six-spindle nut tappers. The product consists of square and hexagon nuts stamped out of $\frac{5}{16}$- to ½-in. metal, with tapped holes from ⅜ to 2 in. in diameter. The stock comes in long bars and is known as standard cold-punching nut steel. As common with this class of stock, there is considerable scale to contend with.

On the punch presses, the soap-water mixture was fed to the dies through a ¼-in. pipe, from which it found its way into a pan underneath the machine. Small individual rotary pumps forced the mixture from the drip pans to the gravity tanks above.

The stampings from the presses fell into iron kegs or pails with perforated bottoms, which were set in the drip pans. These receptacles, after standing in the drip pans for a while, were lifted out, the drippings being supposed to remain in the pans. However, in lifting the cans out a considerable amount of the mixture ran off them, causing a large area of slippery, sloppy floor around each machine. While this loss was not great when calculated in dollars' and cents' worth of mixture, the cost of keeping the floor clean enough so that the men could work at all took the time of two men about two hours a day. It also required two to three men to lift the cans of punchings from the drip pans.

As the lubricant was used over and over without treatment, it soon became full of dirt and scale, which was poured over the dies. Two men consumed at least two hours per day mixing and delivering fresh lubricant to the various machines. When the mixture in a machine became so dirty as to render it unfit for use, it was thrown away. In adding or renewing the mixture the time of the operator and the machine itself was lost, reducing the average efficiency. As the operators were on piecework, any delay cut seriously into their wages. Finally, the management decided that a change of some kind was necessary and began to look into the matter of finding a way to better conditions.

After the subject was looked into to some extent, it was decided to have the Richardson-Phenix Co., Milwaukee, Wis., put in a Peterson filtering system. In the concrete floor under the presses, trenches were cut of sufficient size and pitch so that the mixture would drip from the machines and easily run to a centrally located filter tank set under the floor. The trenches under the machines were covered with gratings of ⅛x⅜ flat iron spaced ¼ in. apart. The gratings were made remov-

FIG. 1. METHOD OF PLACING GRATING AND WORK KEYS

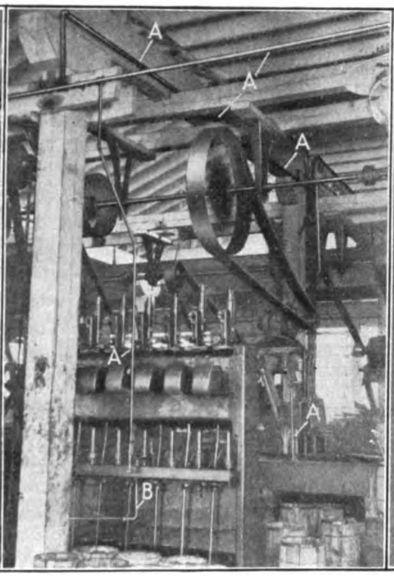


FIG. 2. PIPING TO A TAPPING MACHINE

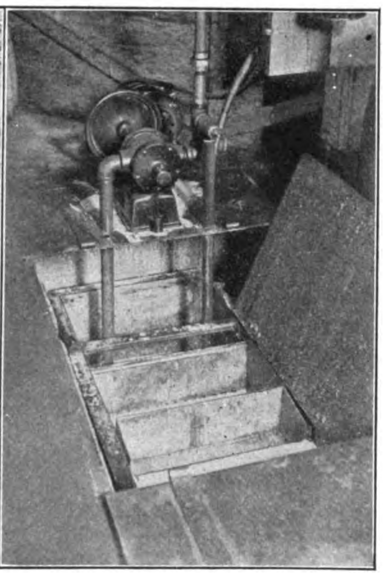

FIG. 3. VIEW OF PUMP AND TANK

able for the purpose of cleaning or repair at any time. The kegs in which the product was caught were placed on these gratings, so that all drippings would flow back to the filter tank. One of the presses so equipped is shown in Fig. 1. These perforated-bottom kegs can be easily and quickly slid out from under the work chute and allowed to drain on a part of the grating as another keg is slipped in place to catch the punchings. This is such a simple operation that one man easily does it where two were formerly required.

As the soap-water mixture finds its way back to the central tank, it is filtered and pumped up through a series of pipes and again poured out to the work and tools at the various machines. This method eliminates the troublesome small gear pumps on the individual machines and saves the men from filling the gravity tanks formerly used—a cause for frequent slops. As the soap water is strained and filtered before entering the feed pipes, the operator never has to worry over dirt- or grease-clogged outlets, but can center his full attention on getting out his work. The even mixture caused by the churning action of the pump is also an advantage.

The tapping machines formerly experienced practically the same trouble as the punch presses and were similarly equipped. The present method of piping a tapping machine is illustrated in Fig. 2. A grating takes care of the drippings from the work in kegs. The feed pipes from the pump are indicated by A. A drain pipe is shown at B. Nozzles are placed so as to pour the mixture over the taps and work as required.

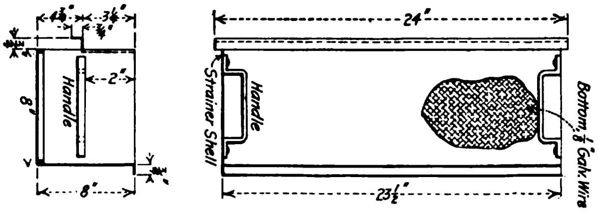

FIG. 4. DETAILS OF STRAINER BASKET

Other Details of the System

As previously stated, the filter tank is placed under the floor, as seen in Fig. 3. The tank itself is covered by a hinged iron cover, shown thrown back at the right. A heavy hinged floor plate is also used. This has been taken off and drawn into the foreground, for photographing. The pipe leading to the pump from the left is the suction pipe. The one at the right is a return pipe fitted with an automatic pressure valve, so that any excess pressure in the overhead pipe will find an outlet and return to the tank. This method keeps an even liquid pressure in the pipes at all times, regardless of the number of nozzles. The pump is a Gould rotary, driven by a 2-hp. General Electric motor running at 1,200 r.p.m. and connected to the pump by back gears. The main discharge pipe is 1¼ in., and the outlets or nozzles are of ⅜- or ¼-in. pipe, reduced at the ends where needed. The drain pipes leading from the trenches are 2 in., leading into 2½ in. and finally into a short piece of 3 in. leading into the tank itself. The quantity furnished at each nozzle varies some, but will average close to 2 gal. per min., one such pump and tank as shown giving about 3,000 gal. per hr.

The arrangement of the filter is shown in Fig. 5. The returning mixture enters at the side into the settling chamber. A deflecting plate diverts its flow downward to facilitate the precipitation of the heavier particles and to prevent short circuiting to the chip or strainer

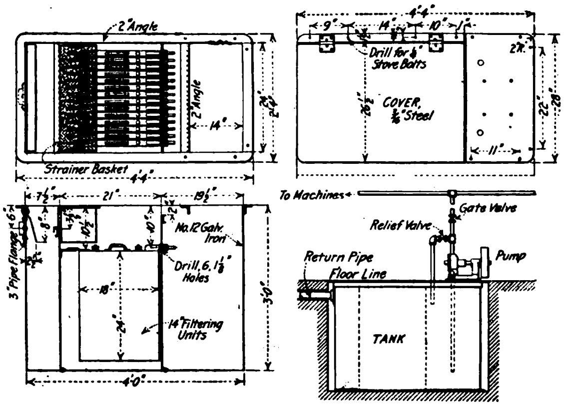

FIG. 5. DETAILS OF FILTER AND TANK

basket through which it drains into the filtering compartment. The latter contains fourteen individual filtering units made of heavy galvanized wire screens held one inch apart in a metal frame over which a cloth filtering bag is easily drawn and held smoothly in place by bringing it over the top and screwing down a cover plate with two thumb nuts. These filtering units, set vertically, filter from the outside to the inside over the entire cloth area under a uniform head. This will be made clear by studying Fig. 6 which illustrates the U-tube principle employed. The head at any point such as X always remains equal to A because the columns of oil on the inside and the outside of the units up to the point of outlet are always in balance. The vertical position automatically tends to keep the filtering surface clean. When necessary any unit can be removed, cleaned or provided with a new bag and

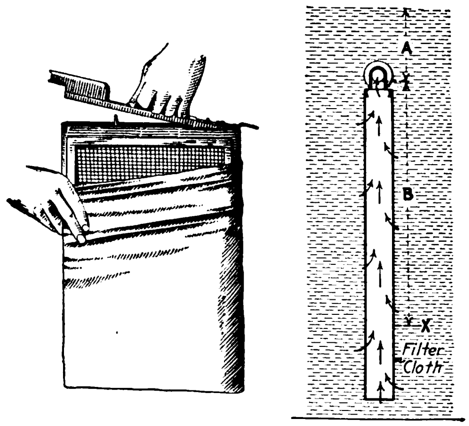

FIG. 6. DETAILS OF FILTER CELL AND ACTION

replaced without interfering with the operation of the filter.

The advantage of having a dirt-free, well-mixed compound is apparent. So also is the advantage of a dry floor and well-drained product. The other advantages accruing from the change in the system are that a large

other advantages
are that a large

amount of unproductive work was eliminated. The men formerly employed to do cleaning, lifting and the like are now transferred to production work, and the machine operators are enabled to keep their minds constantly on their work.

The present system was installed in working order about Jan. 1, 1916. Taking figures from office-record cards, one experienced operator on Dec. 3, 1915, ran out 30,425 nuts in 9½ hr. Sometimes his production was as low as 23,000 per day. On the same size of nuts and the same machine, this operator on Apr. 3, 1916, ran out 44,660 in 9½ hr. His daily average is close to 42,000 per day and is never lower than 35,000. Some of the daily records are worse than this and some better, but the figures in this case seem to be a fair average, everything considered. A conservative estimate is that general shop production has been increased at least 25 per cent. Another thing is that previously the men were paid 10c. per 1,000 pieces on certain sizes of nuts. The present rate is 8c. per 1,000 pieces, and the men make more than they did before the system was installed.

Cam-Milling Fixture

By E. A. Thanton

A special fixture used in milling a double-rise cam on a handled lever and a collar is illustrated in Fig. 1. These cam parts are used on its turret lathes by the W. K. Millholland Machine Co., Indianapolis, Ind. A collar is shown in the fixture, held in by clamps, and a lever is shown in the foreground. The fixture is used in a plain miller and is bolted to the table. A narrow cutter on the arbor is fed across the cut. The cut for the cam rises is made in a series of steps. After each cut across, the handle *A* is pulled, causing the dog *B* to engage the next notch in the segment *C*. This not only moves the work around a little, but also raises it, so that the cutter cuts deeper each time.

This action will be better understood by reference to Fig. 2, where the fixture is shown disassembled. A roller on the end of screw *D*, where it projects through into the inside of the bore of the base, works in the spiral slot *E*, so that as the center part is rotated it is either raised or lowered. The parts are locked solid during the cut by means of the clamping screw at *F*. After the cams are milled in this way, they are smoothed up with a file.

Cutting a Circular Rack on the Miller

By J. Limbrunner

Several circular racks had to be cut on the m
but it was found that they were too large to be s
between the centers of the index head. It the
became necessary to devise some other means for fa
ing and dividing the blank, and the following m
was successful:

A ⅝-in. diameter hole was drilled in the cent
the casting, Fig. 1, on a 10-in. radius. Next, a

Punches and Dies for Making an Embossed Ball

By Robert Mawson

SYNOPSIS—In this article are shown tools for making an ornamental ball used on jewelry. This element is made from flat stock and is first pierced, then embossed and finally blanked into a star-shaped piece, which is then placed in a die. A punch is fed down on it, forming it into a cup-shaped part, which is put into another die. A ball-shaped punch is used on the closing operation.

The Metal Products Corporation, Providence, R. I., makes a variety of sheet-metal parts for the jewelry and similar trades. Some of these parts are plated and polished into finished products. Others are supplied to the trade in the condition in which they come from the press. The tools here described are for making an embossed ball.

This piece is manufactured from flat stock. A strip of brass is fed under the stripper of the die and the holes pierced. It then passes along to the next position, and the surface is embossed by another punch. The strip is fed along to the third position and the part blanked out into a star-shaped element. These three operations are performed in one tool, which is fitted up with the three punches mentioned. It will be seen that, with a tool designed as described, one stroke of the press performs a piercing, embossing and blanking operation.

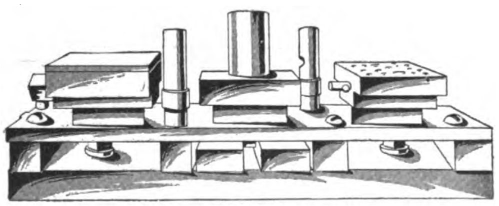
The die has two dowel pins set into reamed holes of the machine to keep the tool square. After the piece has been blanked, it is placed in a circular depression in another die held on another punch press. A punch located in the machine is then forced down on the ball element, making it cup-shaped. The die is fitted with location stops, so that the flat may be placed in a central position on the tool.

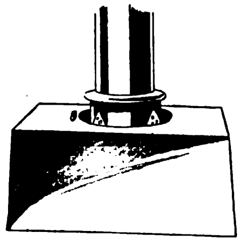
The next operation is the final punch and die work—namely, closing in. The element is placed in a cup-shaped die held on the punch press, and a ball-shaped punch is fed down. As the punch is forced down, the die further closes in the piece, giving it a spherical form. It is then an easy matter to close in the ends into a ball, which is ready for plating and polishing as desired.

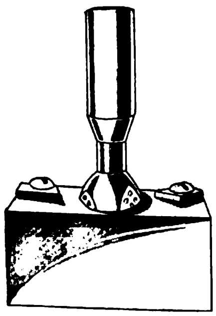
The interesting feature of these tools is the punch and die used for the first three operations. On this tool it will be observed that the stop, which has been cut to the correct width, is pierced, embossed and blanked to the shape shown in Fig. 1. The punches are set at the correct distance apart and held to the punch holder on the press.

The die elments are made of separate tool-steel hardened blocks with the correct contour for piercing, embossing and blanking. These elements are then attached to the die bed at the proper distance apart. The stripper plate, which is made of machinery steel, is fastened to the die bed with screws and dowels. The part as received from these tools is shown, and it will be seen that the impressions and the embossing work have been performed completely on a star-shaped piece. This part is then formed into a cup shape as the next operation.

The element is placed over the die and is located by pins that fit into notches of the star shaper. The punch, which is made with a slightly conical end, is forced down onto the blank and forces it into the circular contour of the die. This operation pushes up the ends of the blank and forms it into a cup-shaped blank. As the punch has a ball end, the blank is made to proper shape.







PUNCHES AND DIES FOR MAKING AN EMBOSSED BALL

FIGS. 2 AND 2-A

Operation—Piercing the blank. The stock, which has been cut to the correct width, is fed under the stripper. As the punch X descends, the brass strip is pierced, and the blank is then ready for the embossing operation.

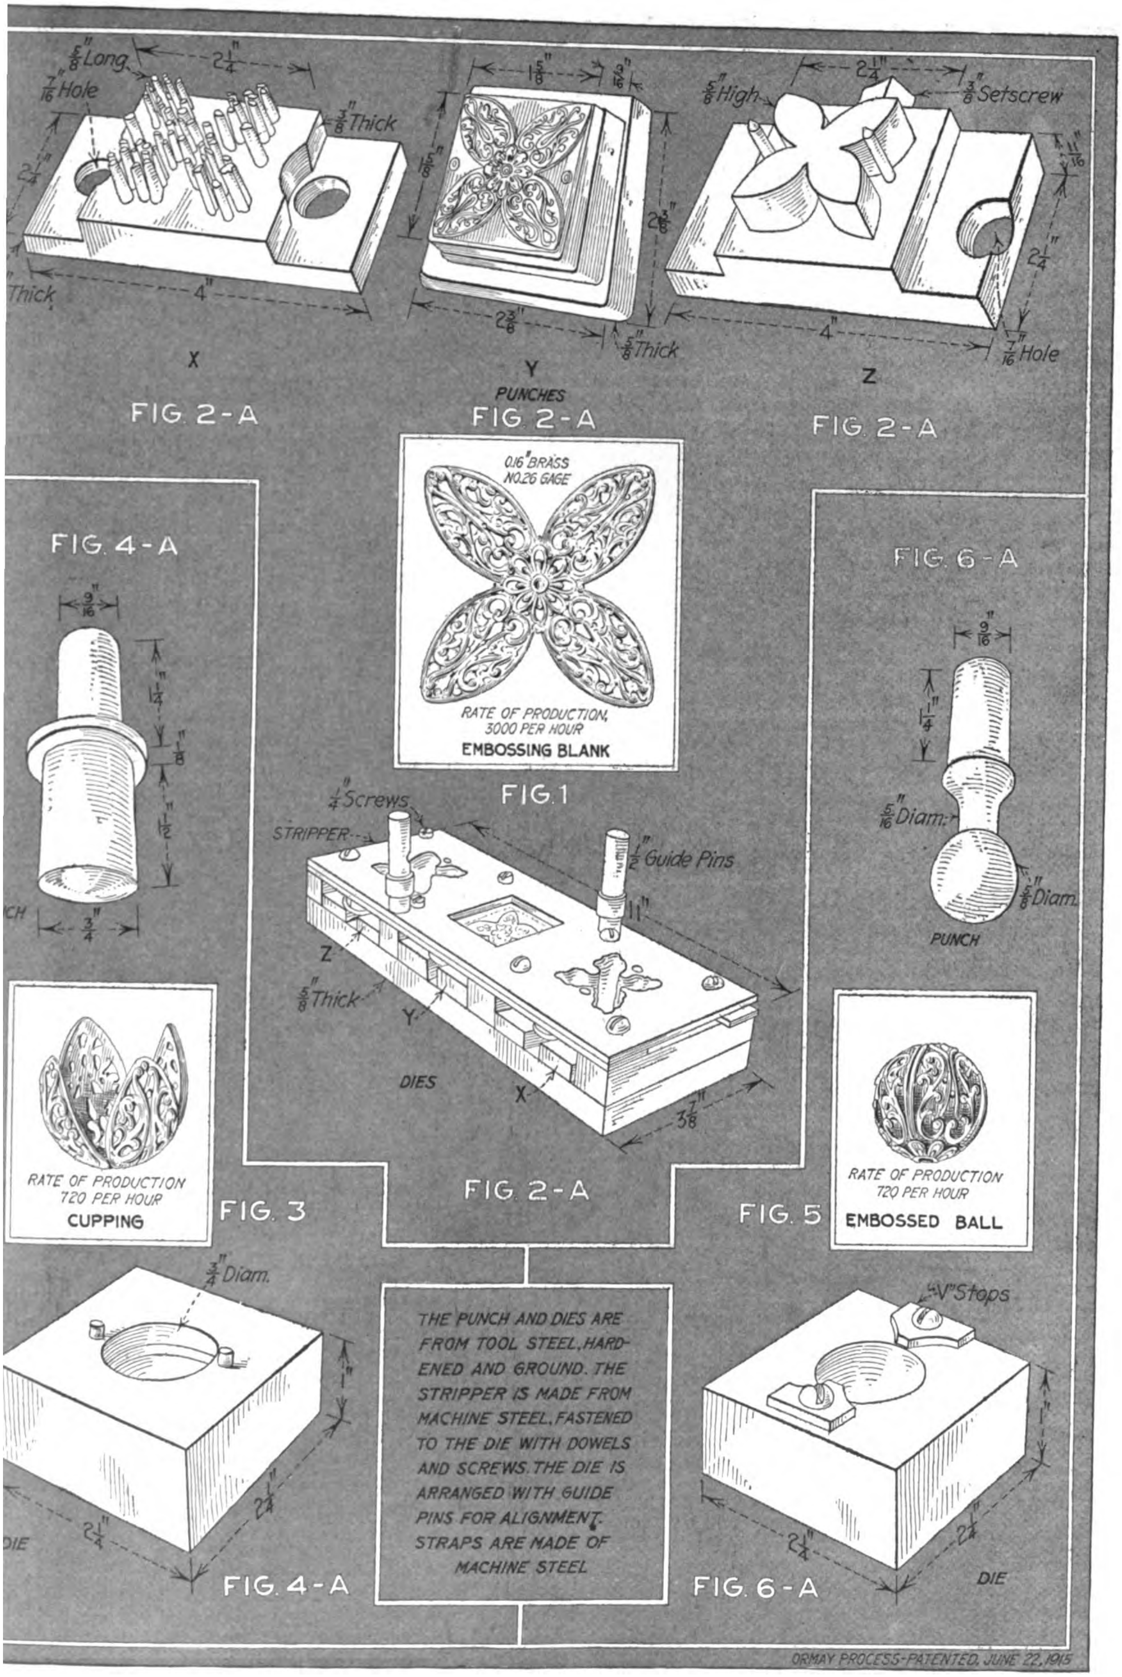
Operation—Embossing the blank. The pierced stock is fed along the die to the second position, and the punch Y being forced down by the machine, the pattern carried on the punch is produced on the brass element. The stock is then fed along to the third position, and the punch Z, being fed down, blanks out the part. The embossed ball at the end of this operation is shown in Fig. 1.

FIGS. 4 AND 4-A

Operation—First cupping to the shape shown in Fig. 3. The star-shaped element is placed over the die, being located by two steel stops. The punch is fed onto the part and forces it down into the circular contour of the die.

FIGS. 6 AND 6-A

Operation—Further closing-in of the cup-shaped element, which is finally given the shape shown in Fig. 5. The piece is placed over the die and is again located by two steel V-shaped stops. The points of these stops fit between points of the star-shaped element. The ball-shaped punch, then fed down, closes in the piece to a ball form.

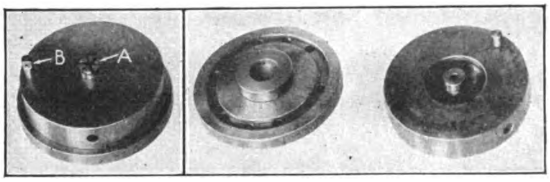


DETAILS OF PUNCH AND DIES FOR MAKING AN EMBOSSED BALL

Close Indexing for Gage Work

Not long ago the Grayson Tool and Manufacturing Co., Indianapolis, Ind., had an order for a special gage made from round stock, to be exactly 0.719 in. in diameter and with six equidistant slots in one end 0.098 in. in width. In order to obtain accurate spacing of the slots a special indexing fixture was made, as shown in Fig. 1. The gage, with the slots roughed out approximately, was set into the center at *A*. The spacing was done by means of the pin *B*, which fitted into grounds and lapped holes in the base. As the work was indexed, the slots were ground to size.

The idea will be better understood by reference to Fig. 2, where the two parts are shown separated. The base is



FIGS. 1 AND 2. INDEXING FIXTURE FOR SPECIAL GAGE

at the left, which is grooved. Buttons 0.40 in. in diameter were used to locate the six holes exactly 2 in. apart. An error of less than 0.0001 in. was allowed, so it can be easily seen that there was small chance for error on the smaller diameter of the gage in the center. The bottom of the upper part, shown at the right, was recessed to fit accurately over the hub of the base. Holes were drilled in the rim of the upper plate for the insertion of a rod to assist in turning it, as the fit was very close.

Station-Type Opening and Closing Drill Jig

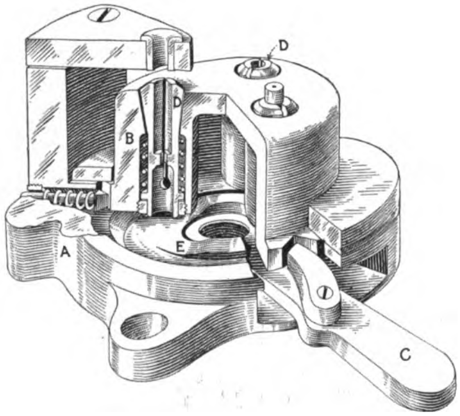
By John J. Eyre

The illustration shows a simple but efficient fixture for drilling small parts used in munitions and other work where the stock is round and large production is required. When work of this nature is drilled in the ordinary box type of jig, held and placed in position for drilling by the operator, the greater part of the time is spent in locking and unlocking the jig, cleaning out the seat for the work and locating the jig in place for drilling.

The fixture shown consists of a bottom plate *A*, which is bored out to receive a circular member, or turntable, *B*, actuated by the hand lever *C* and a pawl. The turntable is bored to receive three or more spring chucks *D*, which are a little larger than the work to be drilled, the action of the spring drawing the chuck into its seat and holding the work firmly while it is drilled. The turntable has at the bottom a flange that is notched directly opposite the center of the chucks, to receive the pawl on the hand lever and a spring locking pin which is on the center line of the bushing that locates the table in the correct position for drilling.

In the bottom plate, on the circle described by the chucks, is bolted a hardened-steel sector *E*, tapered off at both ends so that when the table is moved ahead by the hand lever the bottom end of the chuck will ride up on the hardened surface, thereby compressing the spring and automatically releasing the chuck. While a treadle feeds the drill into the work in the chuck under the drill spindle, the operator removes and inserts the work in the open chuck in front. The sector *E* should be secured to the bottom plate directly opposite the drill bushing, so that the chucks will be opened in front of, and conveniently for, the operator.

When two or more holes are to be drilled in a piece, more chucks can be placed in the turntable and a multi-



STATION-TYPE OPENING AND CLOSING DRILL JIG

drill head used, one drill located over each chuck to drill a different hole. As the work passes along, all holes are drilled. It will be seen that by this method one complete piece is drilled at each movement of the drill head, with the advantage of not being obliged to make the drill head too small for practical work and constant use. Where two holes are to be drilled, a two-spindle head can be purchased and the pitch of the chucks in the turntable designed to fit its centers.

The fixture shown was devised for drilling the spring chamber in percussion pellets for the No. 100 British detonator fuse. The cross-section shows the construction of the chuck and the locating pin in the back of the fixture.

Jigs of this type were also designed for the two holes in the percussion detonator plug and for the four holes in the percussion needle plug, using multidrill heads for both, which meant from four to six times the production and better work.

Taper Boring Arrangement for Making Dies

By E. B. Barker

The following may be of interest to people engaged in making punches and dies for shells. Having a number of dies to make for 18-lb. shrapnel shell and no lathe with a taper attachment available, I rigged up a combination lathe. After the die had been rough-bored and turned, I took a compound slide rest off an old lathe and put it in place of the square-tool post on the saddle. By putting a stud in the center, after the correct taper had been obtained by placing a stop on the saddle to come up against the end of the slide, the taper could be obtained without setting the tool each time.

To get a feed, I took out the screw, put a stud in the top slide and one in a tool box on the hexagon turret. A connecting-rod of suitable length was then placed on the two studs and completed a satisfactory job.

Roll Pressures in Cold-Rolling Steel

By William K. Shepard* and George C. Gerner†

SYNOPSIS—An investigation into the pressures required to cold-roll both annealed hot-rolled steel and unannealed steel that had been partly cold-rolled. Charts and tables give the results for different thicknesses and percentages of reduction. Most of the tests were made on strips 1 in. wide.

Inquiries were made a few years ago of the Sheffield Scientific School of Yale University by Connecticut manufacturing concerns in regard to the roll pressure in cold-rolling brass and steel. As no information could be found concerning this subject, an investigation on the roll pressure in cold-rolling brass was made by the authors of this article and published in the *American Machinist*, Vol. 42, p. 461. The present paper is the report of a similar investigation on steel made in the Mason Laboratory of Mechanical Engineering at the Sheffield Scientific School of Yale University.

The steel was rolled in an experimental rolling mill and the pressure on the rolls measured directly by means of a testing machine.

One grade of steel—carbon, 0.10 per cent. and under; phosphorus, 0.02 per cent. and under; manganese, 0.30 to 0.45 per cent.; sulphur, 0.04 per cent. and under—

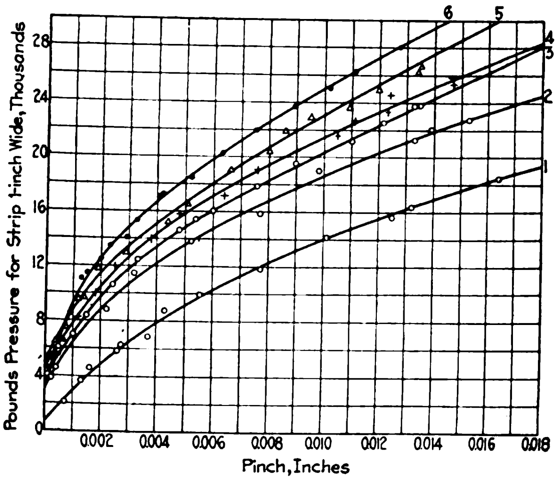


FIG. 1. PRESSURE EXERTED ON 5-IN. ROLLS WHEN COLD-ROLLING HOT- AND COLD-ROLLED STEEL

was used in all of the tests. This steel was kindly furnished by the Stanley Works, New Britain, Conn.

Strips of hot-rolled steel, of steel which had been cold-rolled and then annealed, and of steel which had been cold-rolled various amounts at the Stanley Works and unannealed were all rolled in the experimental mill to determine the roll pressure for these different conditions.

Methods of Conducting Tests

The experimental rolling mill was placed on the weighing table of a 100,000-lb. testing machine. The pinch screws of the mill were held in place by a plate that pressed against the movable head of the testing machine, and the rolls were then adjusted to any desired pinch by moving the head of the testing machine with the hand speed. The diameter of the rolls in the experimental mill was 5 in., and the mill was driven by a motor that gave a speed of 16 ft. per min. for the face of the rolls.

As the steel passed through the rolls, the pressure was transmitted through the pinch screws and plate to the testing machine. The poise of the testing machine was

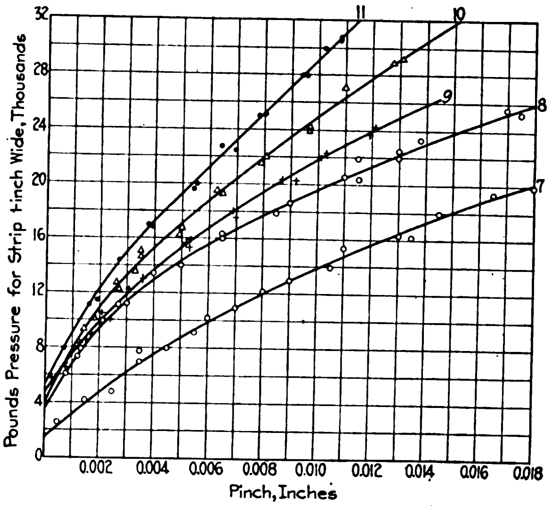

FIG. 2. PRESSURE EXERTED ON 5-IN. ROLLS WHEN COLD-ROLLING HOT- AND COLD-ROLLED STEEL

moved to the proper position to balance this, and the readings from the beam then gave the pressure on the rolls.

In nearly all the tests a strip of steel 1 in. wide was rolled. However, a few tests were made with strips of different widths to determine the effect of width of strip on the pressure.

General Results of Tests

Strips of hot-rolled steel 0.096 in. thick were rolled in the mill. The results of these tests are shown by curve 1 in Fig. 1, and the pressure on the rolls as taken from these curves is given in Tables 1A and 1B.

Strips of unannealed steel that had been reduced from the hot-rolled steel (0.096 in. thick) by a number of passes through the rolling mill of the Stanley Works were also rolled in the experimental mill. The results of these tests are shown by curves 2 to 6 in Fig. 1 and in Tables 2A and 2B. The history of the steel for each group is as follows:

2. Starting with hot-rolled steel 0.096 in. thick, cold-rolled in one pass to 0.081 in. thick unannealed.
3. Starting with hot-rolled steel 0.096 in. thick, cold-rolled in two passes to 0.071 in. thick unannealed.
4. Starting with hot-rolled steel 0.096 in. thick, cold-rolled in three passes to 0.065 in. thick unannealed.
5. Starting with hot-rolled steel 0.096 in. thick, cold-rolled in four passes to 0.0585 in. thick unannealed.
6. Starting with hot-rolled steel 0.096 in. thick, cold-rolled in five passes to 0.051 in. thick unannealed.

*Assistant professor, Sheffield Scientific School.
†Instructor, Sheffield Scientific School.

Strips of hot-rolled steel 0.073 in. thick were rolled in the mill, and the results of these tests are shown by curve 7 in Fig. 2 and in Tables 1A and 1B.

Strips of unannealed steel that had been reduced from the hot-rolled steel (0.073 in. thick) by a number of passes through the rolling mill of the Stanley Works were

8. Starting with hot-rolled steel 0.073 in. thick, cold-rolled in three passes to 0.060 in. thick unannealed.

9. Starting with hot-rolled steel 0.073 in. thick, cold-rolled in six passes to 0.049 in. thick unannealed.

10. Starting with hot-rolled steel 0.073 in. thick, cold-rolled in nine passes to 0.040 in. thick unannealed.

also rolled in the experimental mill. The results of these rollings are shown by curves 8 to 11 in Fig. 2 and in Tables 3A and 3B. The history of the steel for each group is as follows:

11. Starting with hot-rolled steel 0.073 in. thick, cold-rolled in eleven passes to 0.0345 in. thick unannealed.

Strips of steel 0.036 in. thick that had been cold-rolled from hot-rolled pickled steel (0.072 in. thick) in the

rolling mill of the Stanley Works and then annealed 11 hr. were rolled in the experimental mill, and the results of these tests are shown by curve 12 in Fig. 3 and in Tables 1A and 1B.

Strips of unannealed steel that had been reduced from the annealed steel (0.036 in. thick) by a number of passes through the rolling mill of the Stanley Works were also rolled in the experimental mill. The results of these tests

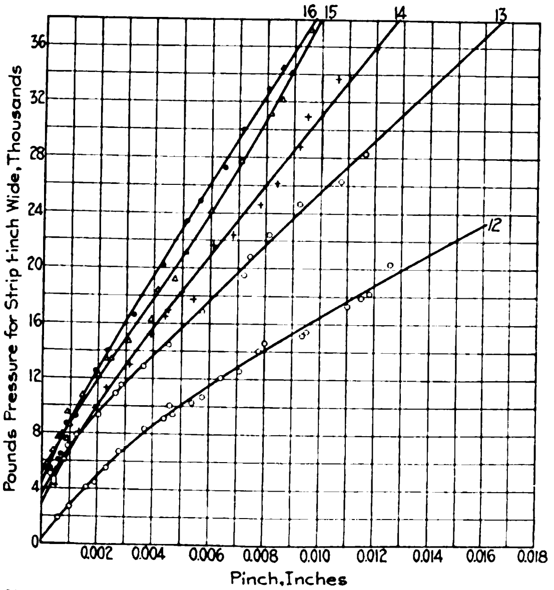

FIG. 3. PRESSURE EXERTED WHEN COLD-ROLLING ANNEALED AND COLD-ROLLED UNANNEALED STEEL

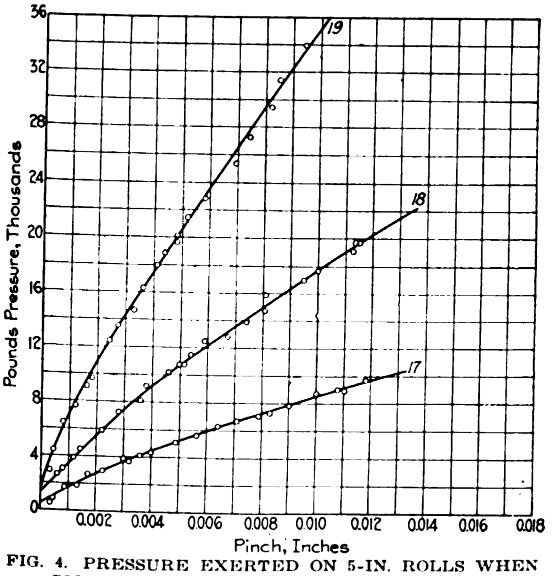

FIG. 4. PRESSURE EXERTED ON 5-IN. ROLLS WHEN COLD-ROLLING ½-IN., 1-IN. AND 2-IN. STEEL

are shown by curves 13 to 16 in Fig. 3 and in Tables 4A and 4B. The history of the steel for this group is as follows:

13. Starting with annealed steel 0.036 in. thick, cold-rolled in one pass to 0.029 in. thick unannealed.

14. Starting with annealed steel 0.036 in. thick, cold-rolled in two passes to 0.027 in. thick unannealed.

15. Starting with annealed steel 0.036 in. thick, cold-rolled in three passes to 0.023 in. thick unannealed.

16. Starting with annealed steel 0.036 in. thick, cold-rolled in four passes to 0.0215 in. thick unannealed.

The effect of width of strip was investigated with annealed steel 0.035 in. thick. Strips of this steel ½, 1 and 2 in. wide were rolled in the mill. The results of these tests are shown by curves 17, 18, 19 in Fig. 4, and the pressures on the rolls as taken from these curves are given in Table 5.

TABLE 5. EFFECT OF WIDTH OF STRIP UPON PRESSURE EXERTED ON 5-IN. ROLLS WHEN COLD-ROLLING ANNEALED STEEL 0.035 IN. THICK

Pinch, In.	Pressure on Rolls (Pounds) for a Strip of Width 2 In.	1 In.	½ In.	Pressure Ratio for Strips 2 In. to 1 In.	2 In. to ½ In.	1 In. to ½ In.
0.001	7,100	3,500	1,720	2.03	4.13	2.04
0.002	10,950	5,500	2,780	1.99	3.94	1.98
0.003	14,300	7,500	3,650	1.91	3.92	2.06
0.004	17,500	9,200	4,450	1.90	3.94	2.07
0.005	20,550	10,750	5,200	1.91	3.96	2.07
0.006	23,600	12,200	5,910	1.93	4.00	2.06
0.007	26,600	13,600	6,600	1.96	4.03	2.06
0.008	29,600	15,000	7,280	1.97	4.07	2.06
0.009	32,450	16,350	7,900	1.99	4.11	2.07
0.010	35,300	17,800	8,540	1.98	4.13	2.08
0.011	38,100	19,050	9,150	2.00	4.17	2.08

When rolls of different diameters are used, the pressure will, it is believed, depend on the projected areas of the rolls in contact with the metal. The meaning of the term "projected area of the rolls acting on the metal" will be understood by referring to Fig. 5.

When a piece of metal 1 in. wide is being rolled between the rolls A and B from a thickness t to t_1 inch, the projected area of the rolls acting on the metal will be equal to b, the sectioned area in the top view.

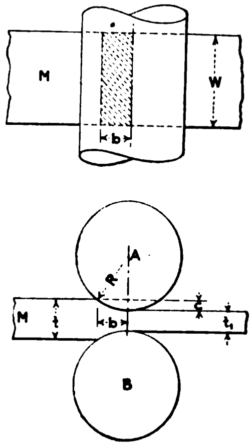

FIG. 5. DIAGRAM OF ROLLS ACTING ON METAL

For a strip of metal w inches wide the projected area will be w times that for a 1-in. width. The per cent. rolling will equal $\frac{t - t_1}{t}$. From Fig. 5 it is seen that the projected area b for any pinch $t - t_1$ on a 1-in. strip can be found from the relation

$$b = \sqrt{R^2 - (R - C)^2}$$

where

R = Radius of the rolls;

$C = \frac{t - t_1}{2}$, or one-half the pinch.

The values of the projected areas of 5-, 8-, 12-, 14-, 16-, 18- and 20-in. rolls acting on a strip of metal 1 in. wide, for different amounts of pinch, have been calculated by the foregoing formula and are given in Table 6.

TABLE 6. PROJECTED AREAS FOR ROLLS OF DIFFERENT DIAMETERS FOR A STRIP 1 IN. WIDE

Pinch, In.	Projected Area (Sq.In.) for Rolls of Diameter 5 In.	8 In.	12 In.	14 In.	16 In.	18 In.	20 In.
0.002	0.0707	0.0894	0.1095	0.1183	0.1265	0.1341	0.1413
0.010	0.1580	0.1999	0.2449	0.2645	0.2828	0.2999	0.3162
0.020	0.2234	0.2827	0.3463	0.3740	0.3989	0.4241	0.4471
0.030	0.2734	0.3461	0.4240	0.4580	0.4897	0.5194	0.5475

When these values are plotted on logarithmic cross-section paper, Fig. 6, it is seen that there is a straight-line relation between the projected areas and the different pinches for each size of rolls. As these lines are nearly parallel, it follows that there is a nearly constant ratio for all pinches between the projected areas of each size of rolls and the projected areas of the 5-in. rolls. The ratios of these

projected areas of different-sized rolls to the projected areas of 5-in. rolls for three pinches are given in Table 7.

If now we wish to obtain the pressure on the rolls for a certain-sized roll, when steel of the composition used in our rolling-mill tests is rolled, we must multiply our values in Tables 1A, 1B, 4A and 4B by the ratio of the projected areas in Table 7 for this size of rolls. For example, the values thus found for the pressure on 20-in. rolls for the hot-rolled steel having an original thickness of 0.096 in. and the steel cold-rolled from this thickness are given in Table 8.

TABLE 7. RATIOS OF PROJECTED AREAS OF DIFFERENT-SIZED ROLLS TO PROJECTED AREAS OF 5-IN. ROLLS

Pinch, In.	Ratios of Projected Areas of Rolls to Projected Areas of 5-In. Rolls, for Rolls of Diameter						
	5 In.	8 In.	12 In.	14 In.	16 In.	18 In.	20 In.
0.002	1.000	1.265	1.549	1.674	1.789	1.897	1.999
0.010	1.000	1.265	1.550	1.674	1.790	1.898	2.001
0.020	1.000	1.265	1.550	1.674	1.790	1.898	2.001
0.030	1.000	1.266	1.551	1.675	1.791	1.900	2.003

Discussion of Results

The speed of 16 ft. per min. for the face of the rolls was chosen for these tests, as similar experiments on brass[1] made by the authors of this article showed that higher speeds than this had no decided effect on the roll pressure. The values given in Table 5 show that the pressure on the rolls approximately increases directly with the breadth of the strip rolled.

In Table 1A it can be seen that a pressure of 21,200 lb. was developed on the 5-in. rolls in rolling 0.073-in. thick

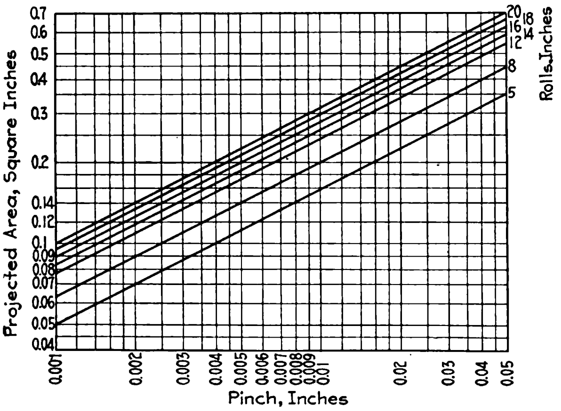

FIG. 6. PROJECTED AREAS OF VARIOUS-SIZED ROLLS

hot-rolled steel, No. 7—a pinch of 0.020 in. In Table 3A it will be seen that about the same pressure was developed on the rolls in rolling the cold-rolled steel, No. 11—a pinch of 0.006 in.

Again in Table 1A it will be seen that a pressure of 9,800 lb. was developed on the 5-in. rolls in rolling 0.073-in. thick hot-rolled steel, No. 7—a pinch of 0.006. In Table 3A it is found that a pressure of 21,300 lb., or more than twice as much, was developed on the 5-in. rolls in rolling the cold-rolled steel, No. 11—the same pinch. A number of similar comparisons may be made by further examination of Tables 1 to 4.

The safe roll pressure for a rolling mill being known from its design, for the grade of steel used in this investigation, it will be possible from the results given here to determine the maximum safe pinch for any initial condition of the steel or properly to design a mill when the amount of rolling required is known.

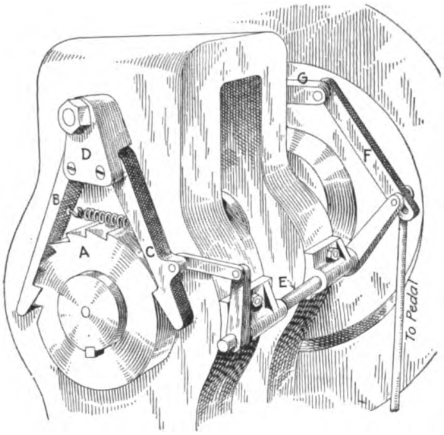
Punch-Press Accidents

By W. Alton

In regard to the different causes of press accidents that have been mentioned, I believe they are occasionally caused by the ram's dropping back after it has nearly reached the top of its stroke. This is not such a rare occurrence when the press is equipped with a friction brake that bears all the time, for it is only a question of time when the brake wears so much that it no longer holds.

To overcome this difficulty the following stop was applied to a press after the ram had dropped and only just missed catching the operator: A ratchet wheel *A* was keyed on the end of the crankshaft. The casting *D* was hung on a stud that was available, and to this the two pawls *B* and *C* were attached. *B* rides on the ratchet all the time and prevents the press from falling back. The shaft *E* was mounted across the front of the press and connected by suitable links and levers to the operating pedal.



THE ALTERATION TO THE PRESS

The clutch lever *G* was attached to the lever on the shaft *E* by the link *F*, having a slotted end so that the first thing done when the pedal is depressed is to withdraw the pawl *C*, and then the press is set in motion. This pawl prevents the press ram from dropping forward if the crank happens to be carried a little past the center.

After applying the above device, we slacked up the brake and ran the press to test it. It worked as certainly as if the brake was on; but if we held off the pawl *B*, it would drop back about once in four times.

Exports of Ammunition, explosives and firearms for the period beginning Aug. 1, 1914, and ending May 1, 1916, according to figures made available by the Department of Commerce, run up to the enormous figure of $480,000,000. It is significant to observe that of this aggregate $188,475,063 was shipped during January, February, March and April of 1916. In classifying these exports the following figures are given: Cartridges, $44,271,750; gunpowder, $127,767,170; other explosives, $195,649,764; firearms, $22,473,934. These figures do not include unloaded shells, of which it is calculated by the department's experts $90,000,000 were exported during the period covered. The unloaded shells are included in the export statements under the general classification of miscellaneous iron and steel products. Prior to the war the total of the exports of ammunition, explosives and firearms amounted to $300,000 per month, which by April, 1916, had risen to the stupendous monthly value of more than $58,000,000.

The Manufacturer's Interest in Vocational Education

By Max B. Robinson*

SYNOPSIS—No one is more vitally interested in the future of vocational education than the builders of machinery, yet in too many cases they are paying little or no attention to it. Changing conditions have made the old apprenticeship a thing of the past, and there is little organized effort to get a practical substitute. The present crisis has shown the scarcity of skilled men. Will the proposed Congressional aid solve the problem, and how can it be best applied?

The vocational-education bill now before Congress contemplates giving to the states an annual sum in excess of $7,000,000 to aid in advancing industrial and agricultural education. As our manufacturers have long sought Federal aid for training workers, it is but natural to assume that they have more than passing interest in this prospective legislation. Unfortunately, however, their active support has been rather meager, and it has been difficult to draw from them any adequate and definite expression of opinion. Industrial production is said to be a feast or a famine, and the feast of today seems to have brought indifference as to the morrow. Should this bill, called the Hughes bill and the Smith bill in the House and Senate respectively, pass the present Congress, the representatives of agriculture and education, and not the manufacturers, may claim the credit for the constructive work.

In the light of facts it seems as though our manufacturers are surely, if unintentionally, pursuing a most shortsighted policy. They rush representatives to Washington to combat dangers that may threaten the tariff, but appear indifferent toward the millions that may or may not be spent for their future workers. They anticipate coming demands for their products and create new designs accordingly, but fail to anticipate their future supply of brains, skill and brawn. They fight inefficiency in most elusive forms in their own organizations, but seem unready to fight a policy leading to future inefficiency or to support actively a policy making for the opposite.

Contrast the attitudes shown toward vocational education by the other interests most affected. Industry has concerned itself with present conditions, expecting others to solve the problems of the future. Agriculture, on the other hand, has recognized the development and benefits that can result from Federal aid. Agriculture has already sought and received Federal aid, as evidenced by the Government researches, by the experiment stations and by the agricultural instruction now given in many rural schools and in our state universities. The agricultural interests are receiving what industry has long desired, but what it has made little effort to obtain. Other interests will be intelligently represented in the administration of any educational bills that may become law.

There are in our public schools today over 19,000,000 children. Approximately 10,000,000 of these will never go beyond the fourth grade; 14,000,000 never reach the eighth grade, and over 17,000,000 never see a day of high school. As soon as the state laws permit, these 17,000,000 children drop out of school and enter agricultural, commercial and industrial life.

As Dean Schneider explains the size of the problem: "If these millions of children were stretched across the country in a straight line, giving one linear foot of space to each child, the line would reach from the upper end of Maine to the lower end of California. That portion which goes through the high schools would reach across the state of California. The rest of the line from Maine to the eastern border of California is drawn into commercial, industrial and agricultural life at about the age of 15 years, with no industrial training prior to going to work and practically no schooling thereafter. This proportion holds in any industrial town or city."[1]

Most of these remain under parental guidance, and many will learn to till the soil as did their fathers. As a group, they cause little anxiety. It is for industry to advance the welfare of the children who are to become its workers and without whom it could not exist. It is confronted by two separate and distinct problems: (1) The securing of workers with general training at least equal to and preferably better than that of our grade schools; (2) the training of workers in jobs for which they have demonstrated talent.

The fact that these problems exist should not be taken as an indictment of our public schools nor of our public-school systems. Although our schools have not provided the instruction that these children over 14 need and desire, industry gave no warning that it could no longer train its own. It outgrew its apprenticeships without notice. Industry, therefore, has helped create the conditions of which we speak, and industry must help apply the remedy. The part which the public schools must play is what we call "vocational education."

The Proposed Legislation

In the light of our problems as stated, it is generally admitted that a comprehensive system of vocational education is a growing necessity. It is also recognized that only Federal aid can make such a system possible in many states. So much has been written on this that argument seems unnecessary. The present emphasis is that the attention, consideration and forethought of all interests concerned are required in the final molding of the prospective legislation and that active effort may be required to secure its passage after its final form is agreed upon.

While the possible success of the present issue cannot immediately nor completely solve all problems, it is expected to stimulate greatly the interest and activity in the separate states. The preamble of the bill before the House of Representatives, the Hughes bill, reads: "To

*Shop coördinator, University of Akron.

[1]From "Industrial Efficiency," presented before the American Institute of Electrical Engineers, April, 1909.

provide for the promotion of vocational education; to provide for coöperation with the states in the promotion of such education in agriculture, the trades, industries and home economics; to provide for coöperation with the states in the preparation of teachers of vocational subjects; and to authorize the appropriation of money and to regulate its expenditure."

Under this bill the appropriations commence in 1917 and increase annually in amount until 1925, after which they remain constant. Appropriations for agricultural education are divided among the states in proportion to their rural population, appropriations for industrial education are divided according to urban population, and appropriations for the training of teachers are divided according to total population. All appropriations are based on the condition that the states themselves appropriate like amounts for the same purposes. No part of the appropriations may be spent for lands, buildings, repairs or rentals, and no part may be used to benefit any religious or privately owned schools. Separate state boards appointed in each state are responsible for all money received by the states, while the administration of the bill itself is to lie with a Federal Board for Vocational Education, consisting of the United States Commissioner of Education and four associate members to be appointed by the President, these to receive a yearly salary of $5,000 each.

Provisions of the Bills

The bill stipulates in broad terms the kinds of schools that may be established, but leaves the details to be formulated according to local needs. Most important among the conditions imposed are that the education shall be of less than college grade; that it shall be designed to meet the needs of persons over 14 who are preparing for farm work, a trade or an industrial pursuit, or who have already entered upon such work; that at least half the time of instruction for persons not employed shall be given to practical work on a useful or productive basis; that at least one-third of the appropriation to any state be applied to part-time classes for workers already employed; that the minimum age limit for evening industrial schools be 16 years and that the instruction therein be confined to that which is supplemental to the daily employment. Certain modifications of these conditions may be made in towns of less than 25,000.

Almost identical in form with the Hughes bill is the Smith bill of the Senate, reported favorably by the Committee on Education and Labor on Jan. 31, 1916, and now on the calendar awaiting consideration. In two most important respects, however, does it differ: First, it provides no money toward the salaries of teachers of home economics; and, second, it provides that the Federal Board for Vocational Education shall consist of the Postmaster General, the Secretary of the Interior, the Secretary of Agriculture, the Secretary of Commerce and the Secretary of Labor, these officials to shoulder the entire administration of the work in addition to their other duties. It also "appropriates" money instead of "authorizing" such appropriations.

At the present time there are differences of opinion regarding certain provisions of the Hughes bill and of the Smith bill as outlined. The committee of the United States Chamber of Commerce appointed to consider the question of vocational education has reported strongly in favor of the principle of Federal aid and of most of the provisions of the bills. It believes, however, that the Federal board of administration should not be constituted as outlined in either bill, but should be representative of all the interests concerned—namely, industry, commerce, labor, agriculture and education. It feels that the importance of the work will demand the entire attention of the board—men unfettered with other duties—and that its members should be paid $10,000 per year instead of the $5,000 provided by the Hughes bill, in order to command the great ability needed. This committee also believes that it should be mandatory that the board appoint advisory committees to represent industry, commerce, labor, agriculture, home making and education and that the appropriations should not necessarily be denied to private or religious schools.

These recommendations are embodied in a new draft of a bill submitted with the report and based, as is the Hughes bill, on the bill originally recommended by the Federal Commission on National Aid to Vocational Education in 1914. The principal recommendations have been submitted, under date of Apr. 1, 1916, for a referendum vote to all members of the Chamber of Commerce. The returns on this vote were due on May 16, 1916.

The total annual sum spent for vocational education under the full operation of the educational bill would be more than double the amount of the Federal appropriation, or in excess of $14,000,000. A goodly share of this would be spent for industrial workers. Whether this would meet the problems or fail to meet them depends upon the present provisions of the bill and upon their future execution. In proportion to the effectiveness with which the manufacturers would have their problems tackled, in that proportion must they share their responsibility in passing the right kind of legislation and in securing proper representation in its administration.

The Responsibility of Manufacturers

What, then, shall be the attitude of manufacturers, as businessmen, toward the framing and the passing of this legislation? Shall the bill be scrutinized carefully for features that may seem objectionable? Shall it be searched for omissions that might lower its maximum usefulness to industry and industrial workers? Shall the importance of the influence of industry in the future development of the education proposed be realized? Or will manufacturers sit with folded hands and silent voices and expect the legislators and pedagogues to do these things for them?

It cannot be hoped that the vocational bill will receive undivided support. There is undoubtedly a type of producer, well known to most of us, who will oppose it most bitterly. This man thrives on the youth of his workers, for his specialized work is mastered by mere children. When their increasing age brings responsibilities that demand commensurate wages, his regard for them has left. They are discharged to make room for younger brothers and sisters and are returned to the world without an education and without a trade. With his short sight, such an employer will oppose anything that savors of even slight inconvenience or expense. He is as great a menace to industrial progress as he is to society at large. Who knows but that the dissatisfaction expressed with the recently enacted vocational legislation in Pennsylvania has come largely from this type?

As stated before, it is not expected that the passage of the Hughes bill will bring a millennium. It is but a step in the right direction. Since its help is indirect, public opinion alone can determine the time and extent of its maximum effectiveness. Like most legislation in a new field, the bill undoubtedly contains both strong points and weak points. But on the whole, it looks sane and reasonable and holds promise.

If the solution of the problem of training young workers is to be permanent, it must ultimately be profitable to both the employer and the worker. It must not exploit the latter and seek to lower wages by increasing the supply of skilled labor; neither must it so educate our youth that they will look down upon work. This is a fit problem for employers and educators, working hand in hand. It is too large for either alone.

Variation of Cost with Volume of Work

By Dexter S. Kimball*

All managers who have cost systems have been confronted with the trying problem of rising costs as the volume of work in the factory diminished. Though much has been written on the general theory of cost finding, this particular feature has not been clearly explained and is not in general well understood. A former article (see page 932) dealt with the rise and fall of costs due to variation in volume of work as affected by the cost of tools or cost of preparation. The present article has to do with the rise and fall of costs with the volume of business as affected by expense or burden.

It should be mentioned that the volume of product passing through a factory may vary in several ways. There may be a uniform increase or decrease in every line manufactured; or some lines may increase or decrease in volume while others do not change; or some lines may increase while others decrease. All these changes may be in any relative proportion whatsoever. The arguments presented will be clearer if only the first two of these varying conditions are considered—namely, when the volumes of all lines rise and fall together, or where some lines fall markedly while others remain normal.

Now if expense varied directly with the volume of work, there would be no change in cost so far as expense is concerned with either of the methods of variation of volume under discussion. Such, however, is not the case. An examination of the expense factors of any enterprise will show that, while some are fairly constant in amount, others rise and fall with increase or decrease in the volume of the business, though not according to the same laws. Thus many expenses that are incident to the very existence of the business regardless of productive operations, such as rent, taxes, insurance and depreciation of buildings, do not vary materially whether the business is active or not. Other factors of expense, such as indirect labor and operating supplies, vary with the volume of business, though not in general in direct proportion to such variations in volume. Thus it requires a minimum amount of oil to lubricate the machinery of transmission when no work is being done, and any more oil is obviously dependent upon the volume of work. Many other expenses have similar characteristics. It is difficult to express these relations in terms of any fixed factor of production, but the general law may be expressed by the equation

$$E = c + fv,$$

where E is the expense, c the minimum constant amount and fv some function of the volume, which function in general is a complex quantity and difficult to express mathematically.

If then the volume of all lines of product decreases, it is obvious that, no matter what method of expense distribution is in use, a rise in productive costs must inevitably result, since the characteristics of expense are alike for all lines of product. If the decrease in volume is great enough, all lines will cease to be profitable because of the irreducible minimum expense. The conditions are analogous to those pertaining to special tools or preparation costs discussed on page 932. If no product is produced, this minimum expense still persists and constitutes an irrecoverable loss.

When Some Lines Are Normal and Others Decrease

If, however, the volume of some lines remains normal while that of some others is markedly decreased, the case is different. Under all averaging methods of expense distribution, such as percentage on labor or percentage on man-hours and where all expense is charged off over current product as fast as such expense accrues, the active lines must necessarily carry not only their own expense, but the expense due to idle tools that may not have been used in producing these active lines. If the volume of the active lines should decrease even a moderate amount, it is obvious that this over-burdening might cause these active lines to be a source of loss, though the efficiency of production was not materially changed. If an accurate machine rate could be made that would distribute all expense in proportion to the use that is made of each and every facility, this over-burdening would not occur and each line would bear only its own just share of expense. Such a machine rate is difficult, if not impossible, to obtain. It will be noticed that the production-center method aims to do the very thing; and in so far as the machine rate of the production-center method is concerned, it is in accord with the theory of proportional distribution of expense. The supplementary rate, however, which grows out of the inherent defects of the machine rate, is illogical in so far as it distributes expenses belonging to one class of work against the cost of another class.

It would seem logical that any product should bear only the expense incident to its fabrication. There would seem to be no reason why one line of product should bear the burden of another any more than that one factory should bear the burden of another factory, simply because they both belong to the same man. It is very difficult, however, in most factories to segregate the expense so as to make proportional allocation of expense with any degree of accuracy, and the assumed necessity of distributing all expense as fast as it accrues is the justification usually put forward for such methods as do sometimes burden one line of product with what really belongs to another. Many accountants and managers insist, however, that the expense distributed against any product should be strictly proportional to the use it has made of the facilities of the factory, and any other expense belonging to any other product should be disposed of in some other way.

*Professor of Machine Design and Construction, Sibley College, Cornell University.

One of the methods suggested for solving this problem is to carry all expenses due to idleness directly to the profit and loss account and charge them off as a loss against the business. The error in the reasoning back of this plan is that it assumes that all machines should be in operation constantly and that, therefore, all expense due to idleness is irrecoverable—an assumption that is not necessarily true. A machine may be indispensable and yet be idle a considerable portion of the time, and the expense charge for such a machine should be set so as to discharge the total yearly expense over the production for that period.

This solution of the problem, furthermore, might often result in carrying to profit and loss an expense that could be included in costs and thus recovered. Aside from any logical principles of expense distribution, expediency would dictate that as much expense as possible should be buried in the sales prices, regardless of the origin of these expenses, provided, however, that this does not destroy the possibility of making sales by over-burdening product that normally would produce a profit.

Distributing by Averaging Over a Year or Longer

Another method of solving this difficulty is to carry all expense to an expense account in the usual manner and distribute it by one of the averaging methods already referred to, but adjusting the rate of distribution on the experience of a year, at least, instead of on the records of the preceding month. The expense account, therefore, will act as a reservoir discharging more of the expenses in busy times and less in dull times. It would of course also equalize periodic expenditures, such as taxes, etc. If the rate of discharge be accurately set, the entire expense should be discharged at the end of the period for which the rate of discharge has been computed. Should there be an undistributed balance in the account at the end of the fiscal year, it can be carried to profit and loss or it can be carried forward into the next period and the rate adjusted so as to distribute it over this period. While this method provides for distributing all the expense without great danger of unduly over-burdening production during dull times, it is of course open to the objections that are urged against all averaging methods of expense distribution.

H. L. Gantt, discussing this problem in an interesting paper presented before the American Society of Mechanical Engineers,[1] argues that "the indirect expense chargeable to the output of a factory bears the same ratio to the indirect expense necessary to run the factory at normal capacity as the output in question bears to the normal output of the factory." That is, if the production falls to, say, one-third the normal volume, this production should be burdened with only one-third the normal expense, so that, everything else remaining the same, the manufacturing costs would not change with volume of product.

Granting that proportional distribution of expense is logical and desirable, Mr. Gantt's contention is true only when the decrease in volume of product is brought about by the complete suspension of production in some lines while the remaining lines are continued at normal volume. His contention will be approximately true also for small decreases in all lines of product. But if a great decrease takes place in all lines of product, a rise in productive costs must surely result from causes that lie in the very nature of expense itself. As has been explained, expense does not in general vary proportionally with volume of product, but there is always an irreducible minimum that must be cared for no matter how small or how great the volume of product may be. If all lines of product continue to decrease in volume, there surely comes a time when all manufacturing will be conducted at a loss; and no method of expense distribution can obviate this result. It will appear from the preliminary discussion in this article of the characteristics of expense that the relation between expense and volume of product cannot be expressed in this simple manner.

[1]See "Journal" of the American Society of Mechanical Engineers, August, 1915, p. 466.

Possibilities of an Intelligently Computed Machine Rate

It would appear that an intelligently computed machine rate in connection with a supplementary rate based on the experience of a long period of time would do much to solve this perplexing problem. Such a machine rate would distribute all expenses that are attached to machines or processes in proportion to the use that is made of them, regardless of the volume of product. The bulk of the expenses would therefore be proportionately distributed even in times of moderate depression. The supplementary account containing the expense due to idleness would be equalized not only over processes, but over periods of good times and depressions, thus minimizing to some degree at least the danger of illogical over-burdening and at the same time distributing all expense into the shop costs. I am not aware that this method has been tried, but it would seem to have some merit.

It should be remembered, however, that all these methods of equalizing expense distribution are helpless against extreme depressions. There is no account to which expense can be carried and disposed of by some trick of accounting any more than it can be safely forgotten. Any expense that is not included in the costs and recovered in the sales is a loss. Furthermore, the entire question of variation in expense burden with change in volume of product is complex. Sweeping generalizations regarding it, or in fact regarding any phase of cost finding, are usually unwise, and the particular phase of cost finding discussed in the foregoing paragraphs will bear close inspection in each case before drawing definite conclusions.

Shop Transportation

By Gustave Remacle

Recently, what at first sight appeared to be a rather laughable method of transportation proved upon reflection to be the best under the existing circumstances. The shop was so crowded with misplaced machines that it was impossible to walk more than four or five paces without dodging or ducking around obstacles. The floor was so wrinkled and full of holes that the use of hand trucks was wisely avoided.

An apprentice was given the task of moving about a hundred large milling cutters from one department to another, care being exercised that they did not become nicked at the cutting edges. He accomplished this by placing ten cutters at a time upon the handle of a broom, dragging the broom along the floor. Transported in this manner the cutters came in contact only at the sides, thus avoiding nicking at the cutting edges. I don't think this method could have been improved upon.

Fixtures Used for Machining Automobile Parts

EDITORIAL CORRESPONDENCE

SYNOPSIS—In this article are shown tools and methods employed in machining automobile parts. The fixture for forming the rounded contour on internal levers is unusually simple in construction. An indexing fixture serves for milling the serrations on brake-lever nuts. The brake-lever milling fixture is made in two parts, which may be placed in different positions on the table to suit various lengths of levers. A fixture for milling the slots in screws is also worth noticing.

The International Motor Co., Mack Plant, Allentown, Penn., is using some interesting methods in manufacturing automobile parts. In Fig. 1 is shown the tool for machining the circular contour of the internal levers. The forging has been previously turned to the correct dimensions. It is then placed in the fixture, as shown, and located and securely held in a machined recess.

The fixture is fastened to the table of the miller. The pin of the lever is dropped into a hole of the arm *A*, which is fastened by a nut to the arbor supporting arm of the machine. Thus when the table is fed along with the 8-in. cutter *C* revolving, the internal lever is swung on an arc and the rounded surface of the part is produced. The cutter operates at 19 r.p.m. with a feed of 0.016 in. per revolution.

In Fig. 2 is shown the fixture for machining the rounded surface around the shaft. The forging is placed in a hole of the fixture *A*, which is fastened to the machine table with the 8-in. cutter *B* revolving at 59 r.p.m. The handle *C*, which fits on the machined square of the part, is swung around. In this manner the surface is given a rounded contour.

The fixture for milling the serrations on the brake-lever nut is illustrated in Fig. 3. The nut is placed in a bushing of the fixture, and by drawing back the handle *A* the part is securely tightened down by friction.

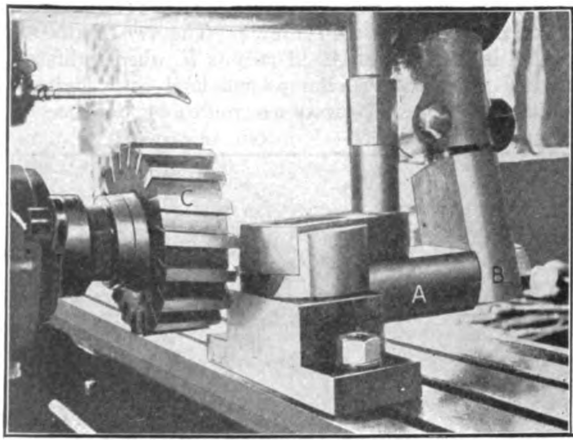


FIG. 1. MACHINING INTERNAL LEVERS

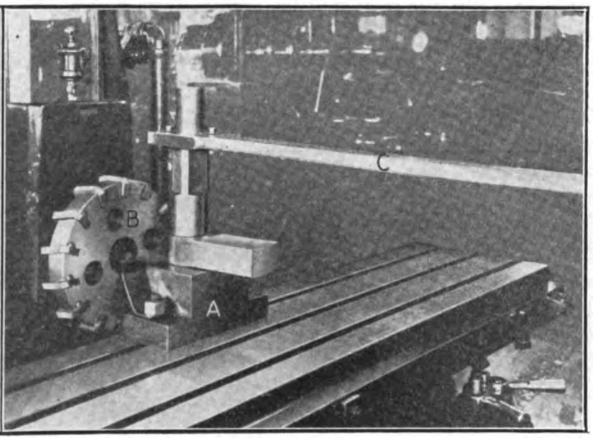

FIG. 2. MACHINING SURFACE OF LEVER

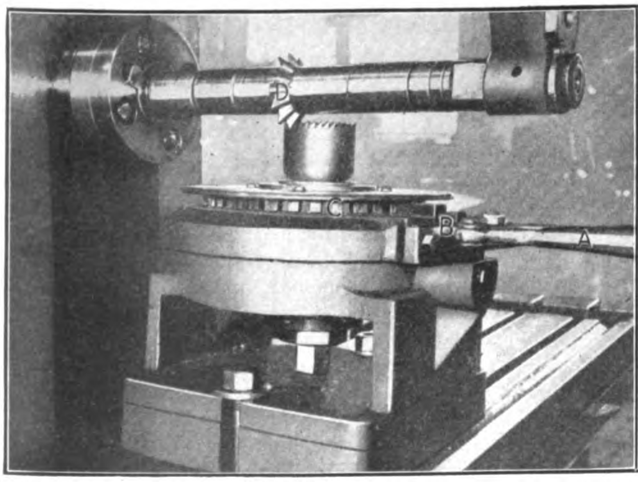

FIG. 3. MILLING BRAKE-LEVER NUT

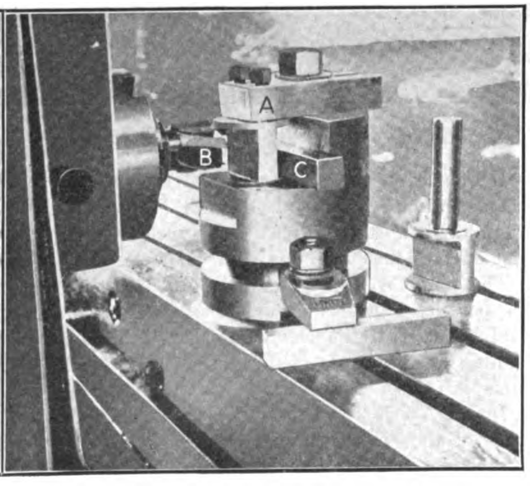

FIG. 4. MILLING THE BRAKE CAM

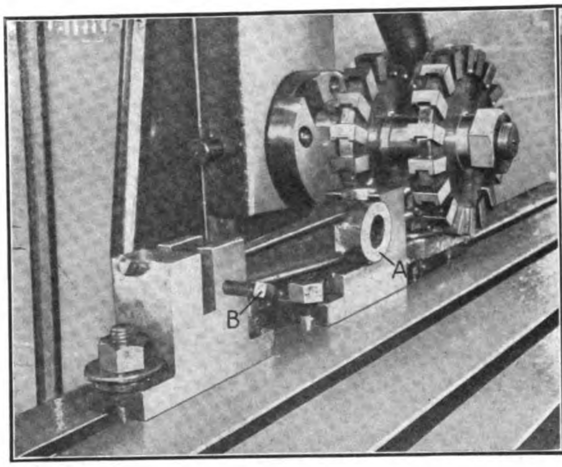

FIG. 5. MILLING BRAKE LEVERS

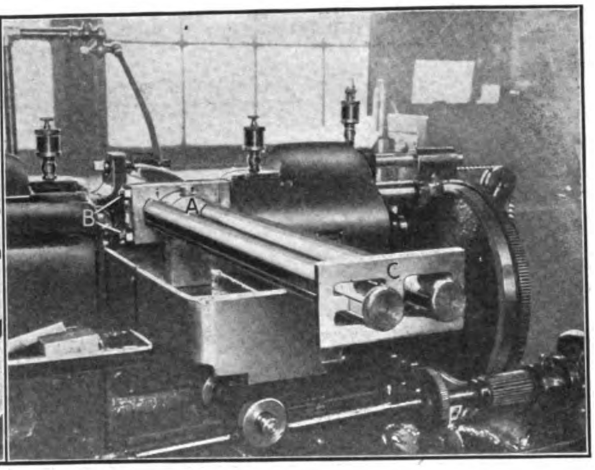

FIG. 6. MILLING SLOTS IN SHAFTS

The various positions are obtained by an index pin at *B*, which drops into the notches of the wheel *C*. After one serration has been machined, the handle is pushed forward, which carries around the chuck holding the part being milled. The handle is then drawn back until the pin indexes, when the lever nut is in position for the next milling operation. The surfaces are machined with the 2½-in. 45-deg. cutter *D*.

The fixture for machining the brake cam may be seen in Fig. 4. The forging is placed in the fixture, the turned shaft fitting into a bored hole. The clamp *A* is tightened on the part to hold it securely. The table is fed against the 1½-in. end mill *B*, operating at 218 r.p.m. with a feed of 0.01 in. per revolution, and the first surface machined until the depth is obtained.

The clamp is then loosened, the cam slid around and the parallel *C* pushed into position. The cam is again held down with the clamp, as described, and the machining operation repeated. One of the machined brake cams is shown at the right of the fixture.

In Fig. 5 is illustrated the method of milling the sides of the emergency-brake levers. The large end is placed in the V-surfaces *A*. The small end of the rod rests on a support and is held rigid by the screw *B*. The fixture is held down to the table with bolts in the usual manner. The surfaces are then straddle-milled with the two 7-in. inserted-tooth cutters operating at 61 r.p.m. with a feed of 0.03 in. per revolution. The advantage of this type of fixture is that the two elements may be placed on the table to suit various lengths.

The fixture for milling the keyways in the service-brake shafts is shown in Fig. 6. The two shafts are located in V-blocks at *A*. The nuts *B*, when tightened, draw together the two clamps and hold both shafts in position. The two keyways are milled by the machine in the usual manner. The shafts are then reversed and the keyways located by the gage *C*, which is made with projections that fit into the machined splines, thus holding them squarely. The other ends of the shafts are located and held in a manner similar to that described. The machining operation is repeated, bringing into alignment the keyways at both ends of the shafts.

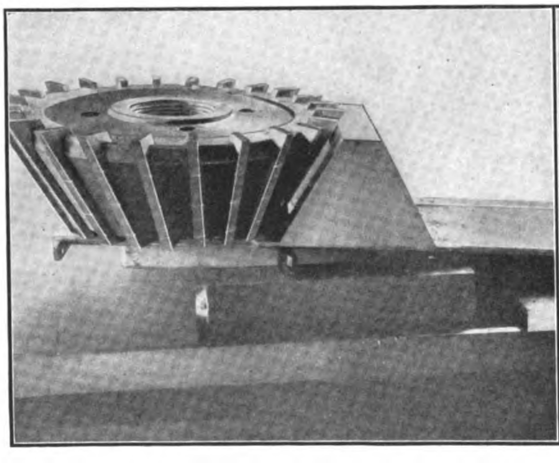

FIG. 7. MILLING BEVEL ON RADIATOR TOP

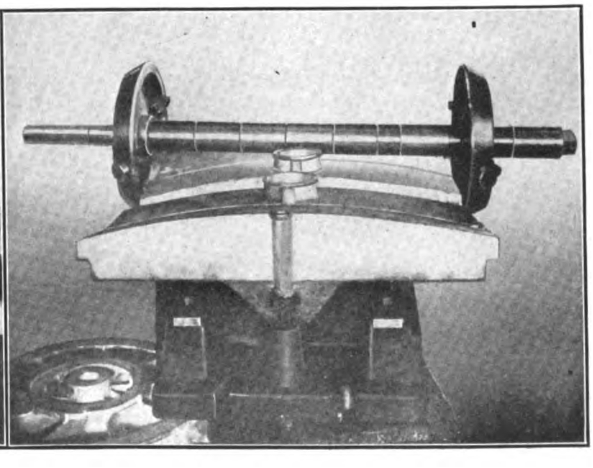

FIG. 8. MILLING SIDES OF TOP

In Fig. 7 is shown the cutter used in machining the beveled surface on the radiator top. This tool is 16 in. at the large end, 5¾ in. high and has an angle of 60 deg. It has 24 inserted high-speed cutter blades.

The cutters and fixture for milling the sides of the radiator top are illustrated in Fig. 8. The cutters,

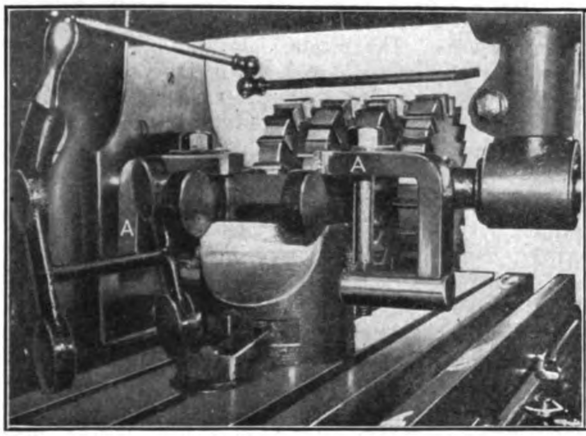

FIG. 9. MACHINING SPRING SHACKLES

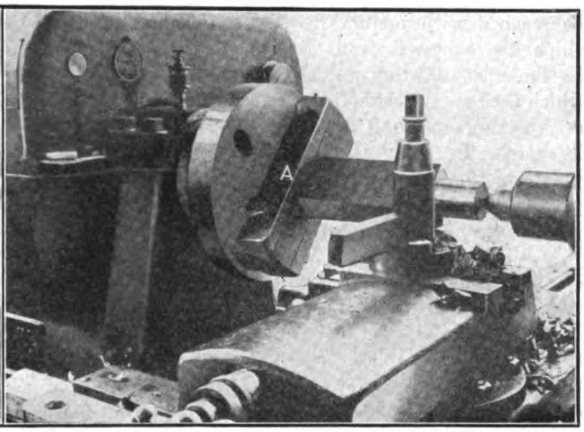

FIG. 10. TURNING BRAKE-SHOE CAM

which are interesting and novel, are 14 in. in diameter. Each has two cutting tools made from 5/8-in. square high-speed steel. They are held in a bushing that is drawn back with a nut, as shown. This type of cutter has proved very successful, producing a good surface. These cutters operate at 163 r.p.m. with a feed of 0.012 in. per revolution.

The fixture for milling the spring shackles may be seen in Fig. 9. The forging is rigidly fastened down with the clamps *A*. The table is then fed against the four 8-in. inserted-tooth cutters operating at 332 r.p.m. After one end has been machined, the table is lowered and fed over. When the fixture is in the proper location, the table is raised and the other end of the shackle machined. In this way the various surfaces are milled in alignment.

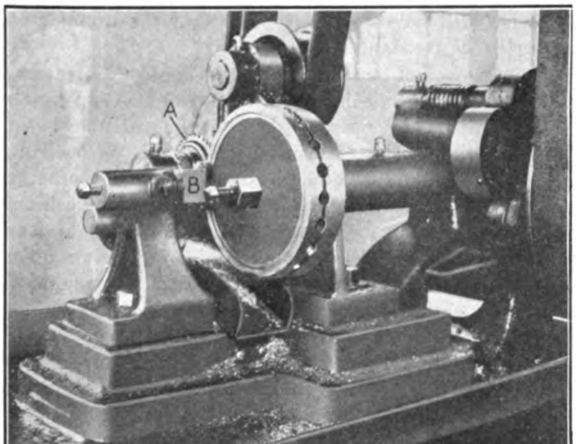

FIG. 11. MILLING SLOTS IN SCREWS

The lathe and method employed for turning the brake-shoe cam are shown in Fig. 10. The rectangular bar is placed on centers and is driven by the sides of the chuck faceplate *A*. These parts are made of 0.20 carbon openhearth steel, and the lathe operates at 160 r.p.m.

In Fig. 11 is illustrated the milling of the slot in headless screws. The parts are placed in the holes shown on the fixture, which carries around the screw against the revolving cutter *A*. When the screw is being slotted, it is held tightly by the adjustable block *B*, which presses against the side of the fixture. As the tool follows around, the pressure caused by the block is removed and the slotted screw drops out. The fixture is thus automatic, the operator simply placing the screws in the holes. The machine will slot on an average of 200 screws per hour.

Disposal of Scrap and Refuse*

By W. Rockwood Conover†

The collection and disposal of scrap merit careful attention. The results obtained from systematic handling of this material in large plants are worthy of consideration. The manufacturer who has given little thought to the subject will find that time or labor expended in conserving and utilizing waste products of the factory is money well invested, and the returns from such labor represent no inconsiderable fraction of his income.

A building devoted to storage and sorting, where these materials can be collected from the several shops, is of advantage. All lots of miscellaneous scrap metals, as well as apparatus to be scrapped, can be sent to this building to be sorted and prepared for shipment to the outside market or for delivery to the home foundries. There is little, if any, material about the factory that has not sufficient value to pay for its handling in this way.

It is often desirable to have borings and turnings of various kinds put into separate barrels or receptacles in the shop and properly weighed and marked, in order to give each department credit for its scrap product when received at the central scrap building. This work can be done by the regular force of floor sweepers or laborers. A practical method of handling steel and iron borings and turnings in large machine shops is to place at several points on the floor sheet-iron boxes or receptacles of convenient size, capable of holding from one-half to one ton and with handles attached to each end for lifting and carrying with the shop cranes to open cars that may be run into the shop. These receptacles should be placed in localities as convenient as possible to several machine tools and where they can

*Prepared for the author's forthcoming book on "Industrial Economics." Copyright, 1916, Hill Publishing Co.

†Factory economist, General Electric Co.

be reached with facility by the overhead cranes. The chips are removed from the machines and deposited in these boxes with practically the same facility with which they are deposited in wheelbarrows, and the expense of wheeling out long distances to platforms or sidings is saved. In manufacturing plants where there is no provision for running cars into the shops permanent platforms with inclined approaches should be erected near the sidings in as close proximity to the shop doors as is possible without interfering with the ingress or egress of production materials, so that the chips can be wheeled and dumped into the cars with one handling.

Collecting Chips from Machines

Too much care cannot be taken in the collection from the machines of such materials as steel and iron borings and turnings, which represent a large proportion of the waste products in many manufacturing plants. The difference in price between mixed and clean borings and turnings is such as to warrant the employment in most cases of sufficient labor to remove the different classes of metals separately, when machines are run on more than one kind of metal. In shops where a large number of machines are in operation it is often desirable to place the collection of chips or turnings under the control and supervision of one person. A man of sufficient intelligence can be selected from the floor-sweeping gang for this purpose without interfering in any great degree with his regular work. The duties of the foreman or assistant foreman in large departments usually prevent either from giving to this subject, except in a general way, the attention that it merits.

The same careful supervision should be given to the separation of brass, composition, copper and other turnings from automatic screw machines and all classes of machines operating on these metals.. A considerable portion of this material can be used at the home plant in making the various alloys for composition castings produced in the brass foundry. Copper and brass turnings that have become mixed with iron, steel or other metals through frequent change of work should be run through a metal separator before shipment to dealers. The difference in price between mixed turnings and pure copper or brass scrap is so great as to render unnecessary any discussion of the subject from the viewpoint of economy and profit. The chips from screw machines or other machines using oil as a lubricant should be run through an oil extractor and the oil separated. This oil is valuable and can again be used for cutting purposes. The net result of reclamation shows a good profit over the expense of operating the separator and of other labor connected with handling the chips.

Collection and Disposal of Refuse

The collection and disposal of refuse is commonly looked upon as an item of dead expense, but even this material has a limited percentage of value which redeems it from total loss. In the erection of manufacturing plants the layout commonly provides for the convenient and systematic handling of productive materials. On the contrary, the economical disposal of refuse or of waste products possessed of greater or less value usually receives but a limited degree of attention. Small dump-cars should be stationed at convenient points alongside raised platforms, so that the material can be wheeled from the adjacent shops or yard and delivered directly into these vehicles. The practice of clearing refuse from shops and depositing it in heaps in the yard and open areas, to be rehandled, is most expensive and is such bad economy as hardly to admit of discussion. The space occupied by these heaps of refuse is frequently wanted for temporary storage of castings or other productive materials, and the cost of removal, especially during the winter months when the mass becomes frozen, is necessarily excessively large. A trial of the system suggested will give results in reduced handling expense that will convince the manufacturer still pursuing the old method. In most establishments the cost of necessary equipment of cars and platforms will be, within a limited period, offset by the economy effected.

A considerable percentage of refuse in many manufacturing plants is adaptable for fuel under steam boilers. Where its consumption in the power house is not deemed practicable or desirable, the erection of a refuse-burning plant of suitable size will permit its being converted into steam for power or heating purposes. In factories where the production materials consist largely of metals the refuse should be inspected before it is fed to the boiler in the burning plant, as the cans or receptacles used for its collection in the several shops will frequently be found to contain pieces of scrap metal that have been thrown in by the careless or unthinking operative. Where no burning plant exists and the refuse from the shops is consigned to one common dumping ground, it is of equal importance that such refuse be carefully inspected and all material of value, such as copper, brass, and other metals, removed and saved. As high an average as 100 lb. or more daily of copper or other valuable metals may thus be recovered. The manufacturer who has not tried this plan will be surprised to find that the dump heap is worthy of constant inspection.

The removal of ashes from power houses and of slag and other refuse materials from foundries also constitutes a large item of expense. Many modern plants are equipped with mechanical conveyors for this purpose. In a large percentage of others, however, the old practice still prevails of wheeling out in barrows to storage heaps and of periodically rehandling these materials to load them into cars. If the accumulation of ashes or other waste products is sufficiently rapid, it is more economical to transfer them directly to cars by means of mechanical conveyors. Even where refuse is used to fill some natural depression, a conveyor system, either alone or in connection with narrow-gage dump-cars, is undoubtedly the most economical and most satisfactory method of disposal. Foundry slag should be carefully looked over and run through tumbling barrels where practicable, in order to reclaim all the metal possible before consigning to the dump or fill.

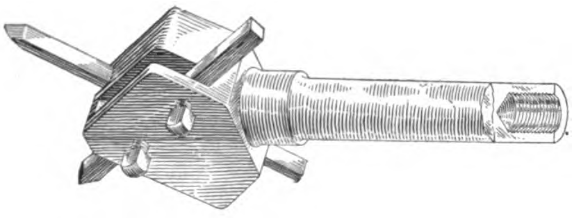
Reducing Glare of Light Bulbs

If prussian blue be applied to the light bulb as far down as necessary to prevent the direct glare of the light from shining in the eyes, it will be found much more comfortable for the workman. It is pointed out by Fred Fruhner. This will throw a bluish light to the eyes, but the direct rays of the light are thrown on the work. The blue should be evenly laid on.

Letters from Practical Men

Adjustable Tool-Milling Cutter

The illustration shows a milling cutter that has given good satisfaction. The holder is of machine steel, with the shank fitted to the miller spindle. The cutting



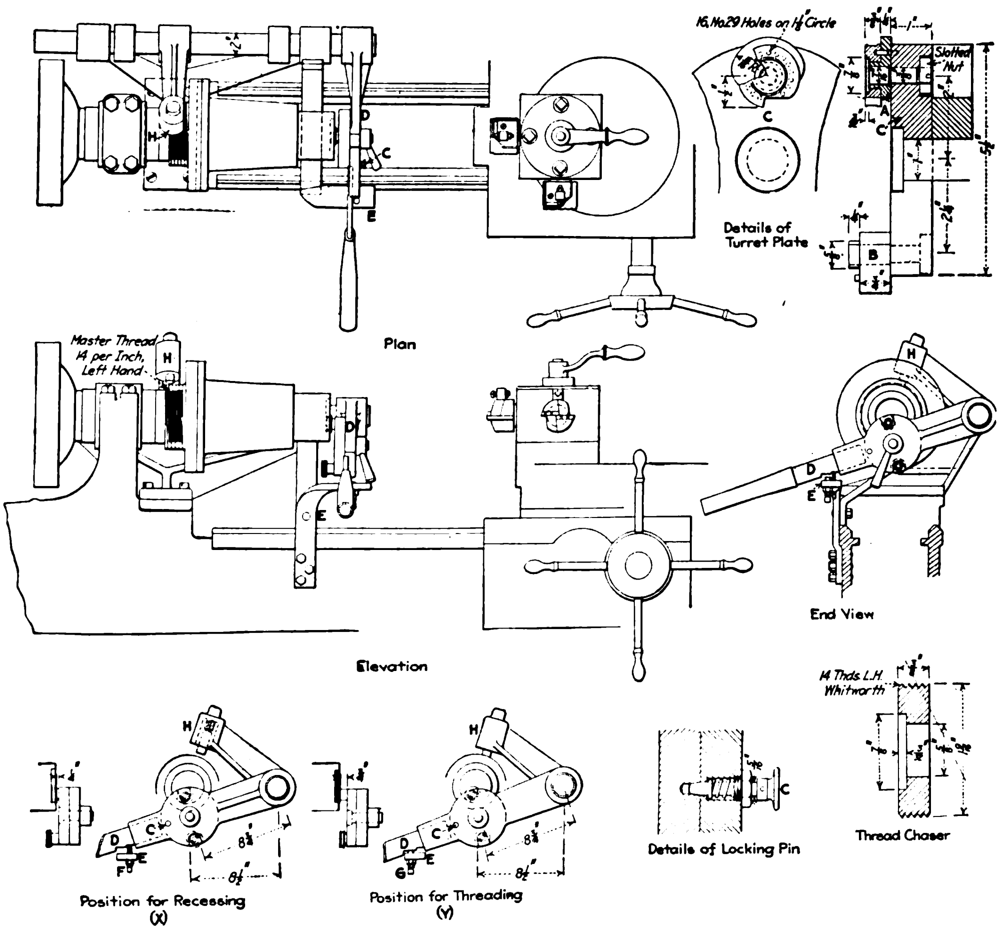
ADJUSTABLE TOOL-MILLING CUTTER

tools are of high-speed steel, square section, and are adjusted to mill various diameters by being arranged at an angle to the center line of the holder. For ordinary setting of the cutters the holder is placed in the miller. Each cutter in turn is allowed just to touch a small surface piece resting on the platen and is then clamped.

Bridgeport, Conn. CHARLES P. BALL.

Chasing Bar Attachment for Threading Shells

The drawing shows an attachment which may be adapted to any turret machine for recessing, counterboring and threading the base of high-explosive shells for the gas plug. The output on 4.5-in. shells is twelve per hour, and the attachment does a superior job when compared with the work of the high-priced thread-milling machines. No rut is left where the cutter starts and stops, but the thread is perfectly clean and continuous throughout. The process is known as chasing with a multiple thread cutter. There is, in addition to the general views of the attachment, an illustration at X of the hand lever for counterboring.



CHASING BAR ATTACHMENT FOR COUNTERBORING AND THREADING SHELLS

Its position in chasing the thread is shown by another view at Y. Details of the turret plate C are also given.

The shell is placed in the chuck; and the recess, which had been previously roughed out on a heavy drill press, is finished with the flat cutters held in the main turret. The turret is run back, and the hand lever with the counterboring cutter in position is brought down as shown in the three general views. The brass follower in H is so disposed that it does not engage the master thread while counterboring the recess. In the details of the turret plate the counterboring cutter holder A is ½ in. thinner than the threading cutter holder B, causing the lever to come in contact with the proper stop screw in the plate E, the one at F being for depth of counterbore and the other at G for depth of thread.

To chase a thread, the operator turns the turret plate to the position shown at Y, moves the cutter up to the bottom of the recess in the shell and bears down. This brings the brass thread follower at H into engagement with the master thread on the hub of the chuck plate, causing the multiple thread chaser to advance the proper number of threads per inch. Several cuts are necessary to finish the thread. When the hand lever comes down on the stop screw G, which determines the size, the thread is finished.

With this arrangement it is impossible for the operator to use the wrong stop, as turning the turret plate determines all the rest. H. P. HOAG.

Brantford, Canada.

Two Handy Planer Tools

In many shops where a variety of planer work is handled, the machinist is often up against it for tools.

The universal tool holder shown in Figs. 1 to 3 takes the place of single-sided tools and tool holders, as it can be used to advantage anywhere they can be used.

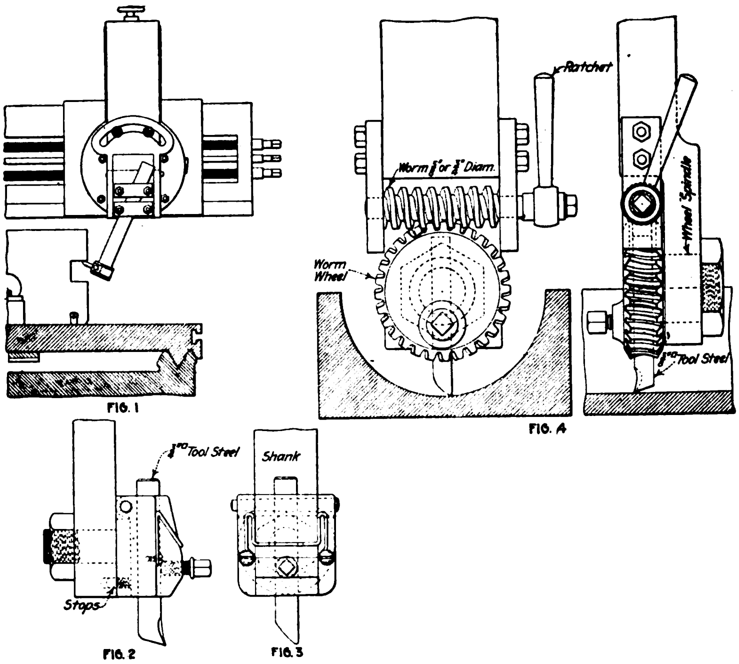
It can be made cheaply, three forgings only being necessary. The shank of the tool should be rather long, and it need only be finished at the bottom, faced on both sides and bored for the swivel-box spindle.

The swivel box and the tool block are machined as shown. The taper-pin hole is drilled with the two parts together. Any kind of spring can be used, but the one shown has proved satisfactory and is of a form quite easy to make.

In use, the apron on the head is blocked to keep it from swinging. The beauty of the lower apron, or clapper box, is that it cannot be set wrong by an ignorant mechanic—when a tool is set to cut one way, the apron must be right.

Cutting out a circle to gage, with a common round-nose tool, is about the most tedious job a planer hand can get. My dislike for such jobs caused me to make the tool shown in Fig. 4. It not only makes the work more agreeable, but does a better job in much less time.

The tool block and its spindle are solid and consist of a wormwheel with a tool slot, a setscrew and a setscrew boss, and a spindle with a nut which should tighten against a shoulder. Meshing in the wormwheel is the



DETAILS OF TWO HANDY PLANER TOOLS

worm shown, held by two plates, cap-screwed to the bar. One end of the worm shaft is squared and fitted with a ratchet handle.

In operation the head is clamped to the rail and the apron set central. The ratchet can be mechanically operated, if so desired, by clamping a stop to the table, high enough to clear the job and move the handle the necessary amount, but owing to the variation in stroke, the hand-operation of this ratchet feed is best and safest in most cases. JOE V. ROMIG.

Allentown, Penn.

Bolt-Threading Machine

Fig. 1 shows a special bolt threader. This machine is of the single-purpose type and was designed for turning and threading the taper thread under the button head of radial stay-bolts. It has a reversible gear drive, mounted on a steel-plate superstructure.

The die heads are arranged so as to be opened by hand by the lever at the side of the head. The top end of the stay-bolt is guided by an interchangeable sleeve in the spindle. Four of these guide sleeves are provided, to take care of all sizes of stay-bolts from 1⅛ to 1⅜ in. inclusive in diameter and of any length. One end of the sleeves has a plain hole and the other end a threaded hole of the respective size of the stay-bolt to be guided. The left-hand die head is furnished with plain cutters, converting it practically into a box tool. The right-hand head has the threading dies. The automatic knock-off for opening the die is not used, because the recess under the head of the bolt is cup shaped and would not permit opening the dies before the bolt is

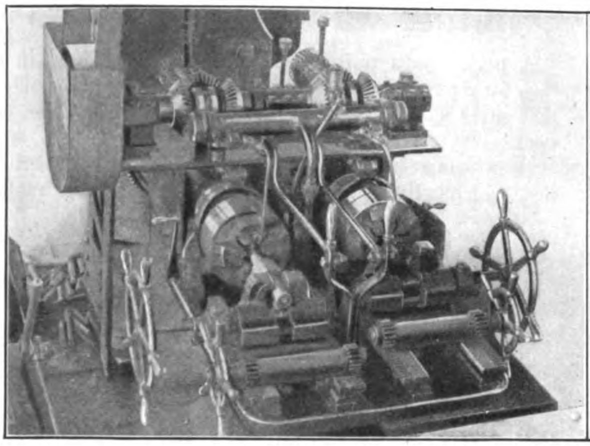


FIG. 1. BOLT-THREADING MACHINE

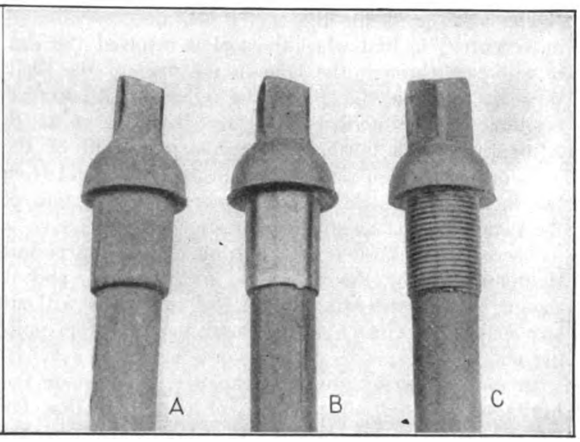

FIG. 2. SEQUENCE OF MACHINING OPERATIONS

backed out a little distance, which is the reason for the reversible drive.

In operating the machine the bolt is placed in the floating holder shown in the left-hand vise. The top end of the rough bolt *A* is entered in the guide sleeve in the spindle, the die head is closed and the bolt fed in by hand. After this operation the bolt looks like *B*, Fig. 2. Next, the bolt is placed in the right-hand head in the same manner. The guide sleeve in this spindle is threaded and can be adjusted so as to bring the threads at both ends of the stay-bolt in correct lead.

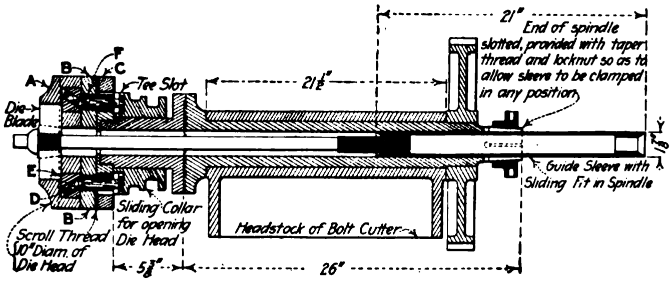

FIG. 3. DETAIL OF SPINDLE AND HEAD

The clutch on the right-hand head is adjusted to slip before any damage is done to the dies, in case the operator should run the die up against the shoulder of the bolt. Before opening the die the machine is reversed about ¼ in., so the dies clear the cupped shoulder of the bolt. After this operation the bolt appears as at *C*. Originally these bolts were turned and threaded on centers in the engine lathe at a cost of over 15c. per piece. With this remodeled bolt cutter the cost per piece has been reduced to 2c. for the finished bolt. This machine has been in service for over a year. It is convenient to operate and gives excellent results.

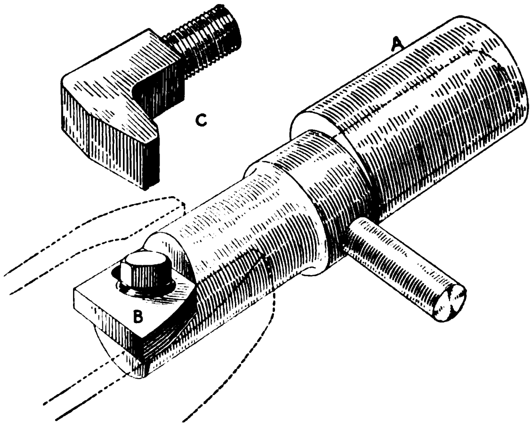
A detailed drawing of the spindle and die head is given in Fig. 3. The die head is shown in the closed position. To open it, the sliding collar is moved backward. The jaws for holding the die blades are made in two halves, *A* and *B*. Fine adjustment is provided by the scroll-thread adjusting ring *C*. The angular T-head pins *D*, which open up the front parts of the jaws, are guided in hardened-steel bushings *E* and *F*, which in turn are tightly pressed into *A* and *B*.

Minneapolis, Minn. WILLIAM SEELERT.

Forming Tool for Adjusting Shells for Weight

The illustration shows a forming tool for removing the surplus length of thread in the nose of the shells, so that the inside of the wall of the shell will match with the end of the nose socket when it is assembled. The amount of metal to be removed is very small, for if the form of the shell before nosing and the shape of the nosing are carefully watched, the length of the thread can be brought quite close to the required dimension, leaving only a shaving to come off to bring it exactly to size.

Some manufacturers are using a collapsible tool that will pass through the hole in the nose of the shell and can then be expanded. My experience with this type is that the chips will get into it and prevent it from collapsing and so give considerable trouble getting the tool out of the shell again. Another method is to make this a separate operation on a lathe, with a forming attachment actuating the slide rest of the machine.



ECCENTRIC FORMING TOOL

The tool shown herewith has no moving parts that can be clogged by chips, and it can be used on the same turret lathe that faces the shell to length and bores and taps the nose.

The bushing *A* fits the turret hole and is bored ¼ in. eccentric, so that when the tool is revolved 180 deg. it will pass through the hole in the nose of the shell. When it is inside, simply turning it back to its original position makes the tool ready for business, as at *B*. After the cut is finished, a reverse movement of the lever brings the tool into a position for withdrawal from the shell. The catches *C* are screwed into the face of the turret and act as supports or stops for the lever.

The eccentric bush is cut open on one side to permit tightening up by the setscrews in the turret, and it should be adjusted to allow the tool to revolve without any shake. The catch will prevent the tool from pulling out.

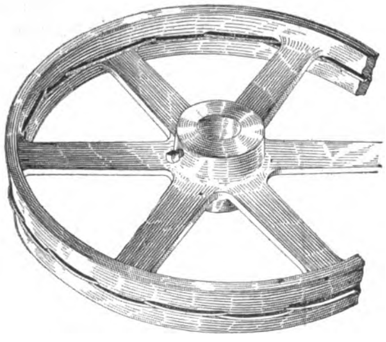
In manufacturing any high-explosive shell where the limits of thickness of the base of the shell allow for metal being removed from the base to bring the weight of the shell within the required limits, a wrinkle is as follows:

After weighing, the shell is marked either O. K. or else so many ounces to be removed. In the latter case the shell is put in a lathe on which the slide-rest screw has a dial that is usually graduated to read in thousandths of an inch. This dial should be removed and a new one put on having divisions so graduated that by advancing the screw one division after the tool touches the shell the tool will remove one ounce of metal from the base of the shell. This amount is usually taken as $^1/_{64}$ in. on the British 4.5-in. shell. With a screw of ¼-in. lead there would be 16 divisions on the dial, each division representing $^1/_{64}$-in. advance of the tool.

New Glasgow, N. S. JOHN S. WATTS.

An Improvised Crown on a Flat Pulley

This simple and effective method was devised for keeping a high-speed belt on a large-diameter iron split pulley driven from a motor. Owing to both pulleys being flat, considerable difficulty was experienced in



AN IMPROVISED CROWN ON A FLAT PULLEY

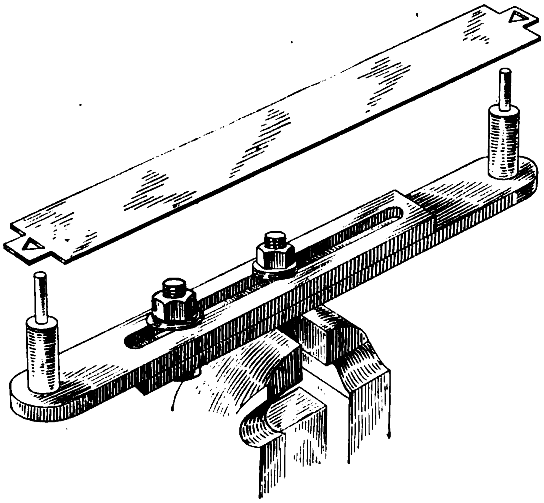
keeping the belt in the center of the pulleys. In the large pulley ½-in. holes were drilled between each pair of spokes and in the center of the face of the pulley. Two belt laces were then threaded on alternate sides of the rim, forming a false crown, as shown in the accompanying illustration. Several methods were tried before this, but without success. I do not remember seeing this arrangement before, but consider it may be a useful kink for any of your readers who have a similar difficulty.

Harehills, Leeds, England. ARTHUR BINGHAM.

Holder for Plated Patterns

A plated pattern is a very hard thing to hold in a vise, for repairing or finishing, so I have devised a holder that saves a great amount of time on these classes of work.

It is composed of two pieces of hard wood, with a slot, which will allow adjusting for any size of plate.



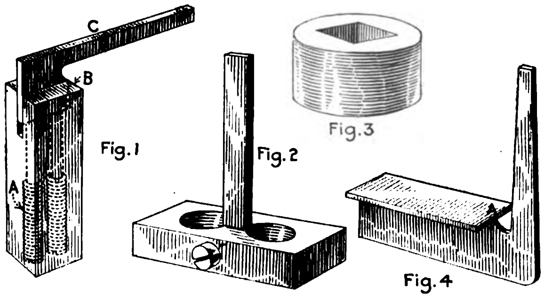
HOLDER FOR PLATED PATTERNS

There is an iron pin at each end to engage the holes in the plate, and the whole fixture is held in the vise by the shank beneath. A. E. HOLADAY.

Naugatuck, Conn.

Some Die Makers' Squares

The square shown in Fig. 1 is valuable for testing when filing out dies. The blade swings on a pin and by means of the screws *A* can be adjusted and held at any desired angle for die work. It should be noticed



FORMS OF DIE MAKER'S SQUARES

that the part of the beam *B* is lower than the blade *C*, thus allowing the operator to see the blade from both ends of the die.

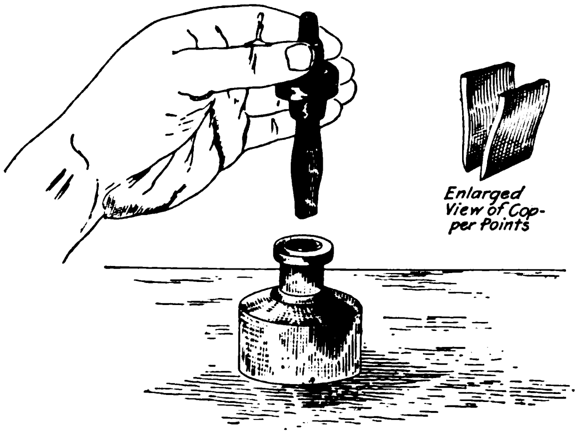
The square in Fig. 2 is particularly helpful in making die bushings, Fig. 3. Bushings of this sort do not present enough plane surface to allow testing with the other squares. Therefore this tool, which spans the opening, is useful for the purpose. In Fig. 4 is shown a handy square that can be made quickly. It consists of two pieces of sheet steel soldered together at *A*.

Newark, N. J. GUSTAVE A. REMACLE.

Discussion of Previous Question

Helpful Drafting-Room Kink

The illustration of my drafting-room kink, on page 188, does not agree with my idea of the quill shape. There is no attempt at pointing the quill pen-shaped in my sketch, but it should be made with a broad pen, such as is used



HELPFUL DRAFTING-ROOM KINK

in sign writing. My description states for what it is used—for quickly changing blueprints by making any inked-in or changed dimension or note more prominent, so that when the blueprint gets into the shop and is handled by oily or greasy hands the important change will still be noticeable. W. J. Gaffke.

Buffalo, N. Y.

Making Patterns and Castings for the Small Shop

On page 667 Mr. Van Deventer points out some of the many troubles the small shop may run up against, especially in pattern work and the foundry. Now I do not mean to criticize any of those statements, but I wish to call attention to certain facts based on experience with a few similar-sized plants with and without foundries and pattern shops. The shop that bought all its castings we will call Mr. Rush. Mr. Rush was a man of the old school, with modern cost ideas, and figured that it would be cheaper to buy his castings, as it would cost him nothing to scrap a defective casting. Therefore the foundry equipment was sold.

The castings in this factory ranged from 1 to 600 lb. in weight. Castings were now bought on contract, but the troubles also began. Different foundries used different mixtures and methods. Hence, some castings would not finish to drawing dimensions; in others the stock was excessive. The best joke on Rush was it did not cost anything to reject a casting. Of course, defective ones were replaced, but not very promptly. I have seen as many as 31 defective castings out of 40 pieces. Now when you figure the delay and the canceled orders resulting from late deliveries, the foundry in a small shop is not such a luxury after all

The other shop, which we will call Mr. Quick, also manufactures a standard article. Mr. Quick began with eight men and bought his castings, but soon found out that he must know what went into his product, which is exactly the same as that made by Mr. Rush.

What I have said regarding the foundry applies equally to patterns made on contract. Of course, I do not mean that all jobbing foundries or pattern makers do poor work; but good work costs more money, and it is always or nearly always the lowest bidder that gets the contract. G. Strom.

Brooklyn, N. Y.

Taper-Shank Drills

On page 554 of the *American Machinist* a writer calls attention to the proportion of drill sizes in relation to standard Morse taper shanks. He says: "The No. 1 taper on the shank does not change over to No. 2 until $^{37}/_{64}$ in. is reached. This leaves too weak a tang for the $\frac{9}{16}$-in. drill, * * * * being out of all proportion to the stresses to which such a drill is ordinarily subjected."

This would no doubt be the result if the drill were to be pushed to the limit of its endurance in hard material on a machine fitted with powerful automatic or power-feed drive.

The writer of the article presumes that it would be just as difficult to have manufacturers of drills adopt changes in the various sizes of taper shanks as it would be to have them all adopt a single standard taper on all tapered machine parts. It may therefore be of interest to call attention to the fact that these changes have already been effected by some makers. For instance, the Birmingham Small Arms Co., in England, has for some time standardized and put on the market small-sized drills with larger taper shanks than the usual older-style standard adopted by the Morse Co. The No. 2 taper takes in drills from ½ to $^{55}/_{64}$ in., No. 3 taper ⅞ to $1\frac{3}{16}$ in., No. 4 taper $1^{13}/_{64}$ to $1\frac{23}{32}$ in. These dimensions approach the changes suggested in the previously mentioned article.

It would be interesting to obtain more information with regard to the Morse Co.'s data, as the sizes may after all have been sound policy from a commercial point of view both in manufacturing and selling, as this company manufactures standard twist drills with taper shanks larger than regular as follows:

Taper Shank No.	Diam. of Drill, In.	Taper Shank No.	Diam. of Drill, In.
2	$\frac{5}{16}$ to $\frac{9}{16}$	4	1⅛ to 1¼
3	$^{37}/_{64}$ to $\frac{29}{32}$	5	$1^{47}/_{64}$ to 2

The same company also manufactures high-speed steel twist drills without tangs, the taper shanks being designed to fit steel sleeves with clutch drive, the drill being entirely driven by the clutch—that is, two flats on the

larger diameter of taper shank—for use where a strong positive drive is absolutely necessary.

Regarding what I have mentioned concerning the data adopted by the Morse Co.'s standard for small drills, consideration must be given to another side of the matter under discussion. Many concerns engaged in producing small work on a manufacturing basis find the No. 1 taper shank a distinct advantage in some respects. Take a case in which much small work is drilled to jigs in multiple-spindle machines, or light work of a delicate construction is drilled in single-spindle machines. The size of the taper hole in the machine spindle is usually taken as a basis for selling or purchasing purposes. As conditions exist, a machine with a larger-sized taper hole in the spindle would obviously mean an increase in price for the plant, and again the advantage of a wide range of drills with No. 1 taper shanks is well known to those who use quick-change turrets or interchangeable collets for single-spindle drilling, reaming and tapping operations.

In conclusion it seems that the safest policy regarding drills, as with numerous other small tools, is "the right tool for the job." If tangs are broken through using improper sizes of shanks for heavy work, resort can always be had to various devices that it pays to stock in any well-equipped toolroom—"Use-'em-up sockets," for instance, which drive the drill by a flat ground on the shank in much the same way as the clutch drives on larger drills; or "Cleveland" double tang and drill sockets, both types of which are shown in the sketches.

Pratt & Whitney, of America, and Vickers, of England, have coöperated in the production of vanadium high-power drills twisted from flat bars with taper shanks formed by an increased twist. Their contention is that with these taper shanks there is no strain on the tang and that it is impossible to break it under any condition of drilling. The No. 3 taper starts at $^{51}/_{64}$ in., No. 4 at $1^{7}/_{64}$ in. and No. 5 at $1^{43}/_{64}$ in. I understand the smallest shank is No. 2. With this size of shank, drills are made from $5/8$ in. diameter.

The writer's experience with this type of drill has been confined to the 1-in. diameter. It can certainly take an enormous power feed without the least sign of destroying the tang. J. H. HORNER.

Glasgow, Scotland.

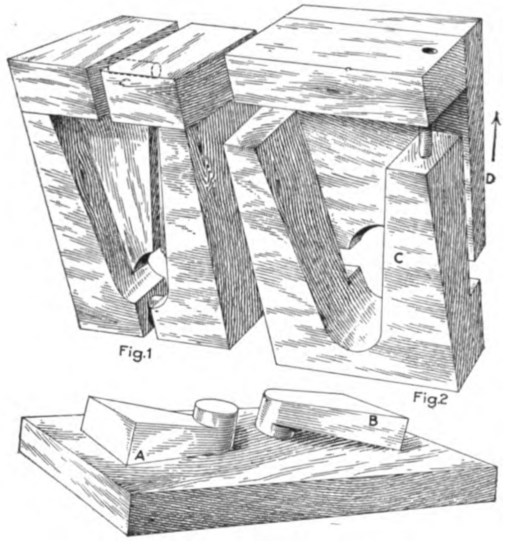
The Best Way to Make Cores and Prints

On page 640 is an article on the making of core boxes for what are known as tail-print cores, showing an "improved" way of making the core box, Fig. 2, over the old and time-honored way, Fig. 1. In making patterns and core boxes, the pattern maker must at all times bear in mind the fact that his labor and its products are not the end, but only a means to an end—namely, producing castings. Anything in the pattern or core box that would entail extra labor on the part of molder or core maker is not the best practice.

In the core box, Fig 2, it would be necessary to lift off the side of the box having the circular hole or holes and then turn over the box with the same side down before lifting off the other half. The core would be left in the position B on the drying plate, resting on the inner edge of the circle and the inside edge of the tail core, causing sag in the long tail cores and bruising the sand on the sharp edges, thus making an imperfect core.

In the old way, where the box is split on an even center, one can give all the draft required on both sides and face. When the core is rammed up, the box can be turned over with the tail side down on the flat side. The box can be taken off either side, leaving the core in the correct position on the drying plate—namely, on a flat surface, as shown at A—fully supporting the core till baked.

Personally, I should hate to suggest to any practical core maker that he make cores in the box Mr. Eyre speaks



TWO WAYS OF MAKING TAIL-PRINT CORES

of, in preference to the old-style box. As far as expense of core boxes is concerned, one could make two of the split-in-center type to one of the kind suggested on page 640. JOHN PARKER.

Boston, Mass.

[There is no reason why the core box, Fig. 2, should not be laid with the face C on the core-drying plate and rapped lightly while the part D is drawn in the direction of the arrow, after which the part C is either drawn in the opposite direction or lifted vertically.—Editor.]

Wasted Intervals in the Small Shop

With all the talk about rapid production and cost-reducing methods in the large munition factories and other manufacturing plants, it has often occurred to me that a great many of the methods used could, with modifications, be applied to the numerous small shops scattered throughout the country. Obviously, many of the developments could be used only where there is mass production, but others are broader and in some degree could be applied to almost any shop employing more than two or three men.

The division of labor can be used as an example, for I believe from personal observation that here is where the most glaring examples of small-shop inefficiency are to be found. It is a common sight in hundreds of small shops to see a first-class machinist start a piece of work and follow it through the different operations, often at-

tending to the most simple processes on it. This is unnecessary, for in almost any shop where there are two or more machinists there are, or ought to be, one or more helpers who could do some of the simpler parts of the work, such as centering shafts, almost all drilling, etc., as well as the skilled worker. This is not efficiency that requires long study or working out with a stop watch, but just a little foresight and tact on the part of the foreman. It would be surprising to some to know how many shops there are, employing a few men, in which all the workers are rated as machinists, with the possible exception of a boy who, for convenience, is known as an apprentice.

This practice of following a job seems to be the traditional way of doing the work and for that reason might appear hard to change in some localities, but it seems to me that any reasonable man ought to see that it is unsound to have a 40c. man doing 20c. work. If a man is capable of earning 40c. or more an hour, he should see the reasonableness of keeping him on 40c. work as much as possible. The very fact that he is able to earn these wages shows that he can reason at least that far.

Right here I should like to say a word for the foreman, who is supposed to plan all this. In many of the very small shops, besides supervising all the work and planning the next job, he is expected by the owner to turn out a certain amount of actual work himself. And in the slightly larger shops, say those employing from 20 to 50 men, the tradition seems still to linger in the minds of the owners that there is no limit to the power of expansion of a foreman. I personally know of shops doing a jobbing and repairing business where the foreman has charge of 50 men. He has a few so-called "strawbosses," who are supposed to be of great assistance to him; but as they usually have no real authority, they seldom accomplish much beyond seeing that the younger workers do not actually sit down. Of course, there are superintendents and others in authority; but the actual details of operation are left to the foreman, who attends to as many as he is able and of necessity lets the rest go.

Another thing quite noticeable around small shops is the care of drills—or rather the lack of care. Some drill-press boys handle the drills and reamers in the same way that they handle the clamps and rough bolts. The drills are all piled together on a bench or table and dropped on the floor and the shanks dented, until I sometimes wonder how they are able to produce holes at all.

I have found it a good plan to acquaint the drillers with the value of drills, reamers and similar tools. Very few seem to have any idea of the cost of such tools and are usually quite astonished when told the actual price. This information generally results in much more gentle handling of the drills thereafter, for very few willfully maul tools when it is known that the price runs into a considerable amount of money.

I wonder how many owners, unless they are around the shop most of the time, know that in the majority of cases the drills are returned to the toolroom and put in the racks without being sharpened, with the result that the next man who wants to use one has to wait for it to be ground, even though he is the highest-paid worker in the shop.

In this connection a simple plan for shops too small to have a more complete system is to have a boy—apprentice or otherwise—whose duty it is to make the rounds of the machines at regular intervals, return to the toolroom all drills and other tools that have been used and bring to the machine such ones as will be necessary for the next job. The boy might not be at the machine every time a change was being made, but he would save the machinist a great many trips and the group of men waiting at the tool window would be noticeably smaller.

Another thing that many owners neglect is to provide plenty of tool steel. I have often seen a lathe hand roughing down a big shaft and using just one tool. When this became dull, he stopped the machine and went to the emery wheel. This is surely false economy, especially since most small shops use tool holders and bits and the additional outlay for tool steel would be over-balanced many times by the minutes gained, remembering that no matter how many tools are used the actual steel consumed will be the same.

There is another tradition that I believe small-shop machinists ought to have outgrown by this time, but it is prevalent to a surprising degree in repair and the smaller marine and jobbing shops. It is the idea that a first-class machinist should not be told too minutely how to do a piece of work given him. The man receives the rough material and a drawing, and any information as to the details of doing the work is usually resented as reflecting on the ability of a first-class mechanic. Many times the work is not done in the most economical way; but if the method used is at all reasonable, the foreman, to keep peace in the family, says nothing, This is something that the owner is not apt to notice, unless he is an expert mechanic himself or has an elaborate cost system, which last is rather rare in the types of shops mentioned. By this time the mechanics should realize that the machinist's trade has grown too big to be entirely learned by any one man and that suggestions as to methods can be given to the best of them.

Of course, all of this seems out of place and unnecessary to the large-shop workers, who are used to the subdividing of the foreman's duties and the instruction card with exact directions; but it should be remembered that there are hundreds of machine-shop workers who never even saw an instruction card or heard of a speed boss. The only effort most of the owners of these shops seem to be making to cut production costs is to experiment with higher speeds and bigger feeds, overlooking the leaks that are much more important, for in most shops the amount that cuts can be speeded up is very little without an almost complete change of equipment.

I believe that if many owners would give more time to some of these things and to what John H. Van Deventer calls "intervals" and less to speeding up the cuts, they would soon have the means to buy modern equipment, which they could speed up to the limit without any experimenting. E. W. WRIGLEY.

Seattle, Wash.

Compulsory Adoption of Metric System

In these days when Mr. McAdoo is being asked by the Bureau of Standards to push along the compulsory adoption of the metric system into this country by advocating it at the conference in Argentina, it is interesting to have a little side light on Argentine conditions as regards the use of the metric system.

The following excerpt from the May number of *The Americas,* published by the National City Bank of New York, is from an article on "How to Translate Argentine Prices." It will be noticed that while the metric system is by law made compulsory in Argentina, they still continue, according to this article, to measure great estates in square leagues and the square league varies in different provinces.

Also, according to this article, occasionally old Argentine measurements and weights come up and puzzle the country, and the list shows that there are a good many of them. Evidently there would be as little success in this country in abolishing our own present measurements as there would be in any other country, and this article merely confirms the mass of other evidence offered by Mr. Halsey and Mr. Dale to the effect that a compulsory metric system merely adds another system and does not replace the old units. The extract referred to is given herewith:

Great estates in Argentina are often measured in square leagues. The square league is measured differently in different parts of the country, being equal to 10.4255 sq.mi. (6,671.66 acres) in Buenos Aires, Santa Fé and Entre Rios provinces and to 9.6529 sq.mi. (6,177.85 acres) in the National Territories, with varying sizes in other provinces. In San Luis, Mendoza, San Juan and Catamarca the square league equals 2,615.627 hectares; in Cordoba, 2,709.827; in Corrientes, 2,701.088; in Tucuman, 2,662.560; in Santiago del Estero, 1,880.485.

These are the metric measurements. Occasionally the persistent "old Argentine" measurements come up and puzzle the reader. A few of them are:

Onza = 1.012803 oz. = 28.7125 grams
Libra = 1.012803 lb. = 0.4594 kilos
Arroba = 25.32 lb. = 11.485 kilos
*Quintal = 101.28 lb. = 45.94 kilos
Tonelada = 0.904288 English tons = 0.9818 metric tons
Pulgada = 0.947 in. = 2.4055 cm.
Pie = 0.947 ft. = 0.2886 m.
Vara = 0.947 yd. =0.866 m.
Cuadra = 4.17 acres = 1.6871 hectares
†Cuartilla = 7.549188 gal. = 34.2992 liters
†Fanega = 3.774594 bushels = 1.3719 hectoliters
Cuarta = 1.0455 pt. = 0.5937 liters
Frasco = 2.091 qt. = 2.375 liters
Galon = 3.345 qt. = 3.800 liters
Barril = 16.728 gal. = 7.6 decaliters
Pipa = 100.37 gal. = 4.56 hectoliters
Pesada of dry hides = 35.448 lb. = 16.079 kilos
Pesada of salted hides = 60.768 lb. = 27.564 kilos
Pesada of washed sheepskins = 30.384 lb. = 13.782 kilos

*The international quintal is a metric measurement equaling 100 kilos.

†These have also other values as variously stated.

Cincinnati, Ohio. E. F. DuBrul.

Your editorial on page 563 and also Charles M. Muchnic's article on page 692 again open a discussion which comes up from time to time and which is of especial interest to the American mechanic. Some years ago a crusade was put on foot to change the existing English standard of measurements to the metric system. This crusade was short lived, as the bulk of the manufacturers of this country could not see the need nor the advisability for such a step.

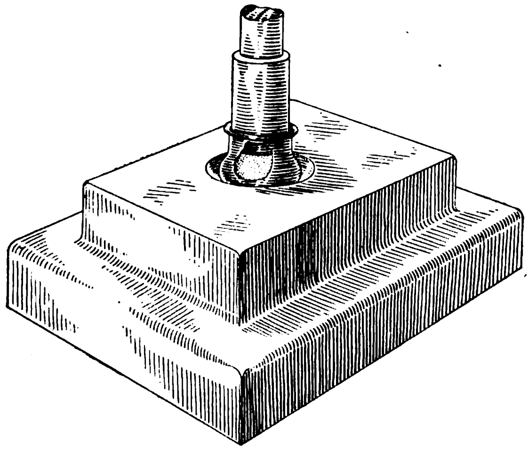
Personally I have worked about eight years using the metric system and can say that it is the simpler of the two; but let the men who are advocating the metric system stop and consider the enormous loss in discarding small tools and instruments that the change will bring to the machinists, carpenters and all trades using linear measurements. This loss will be great even if the change comes gradually, to say nothing of the expense to manufacturers in altering equipment to meet the new conditions. That the metric system must come gradually—and very gradually—if at all, is a foregone conclusion. Any attempt to rush matters will surely end in failure, because of the vast amount of labor and money it will involve.

Speaking of the Latin-American and European countries using the metric system and our export business with them, let the American manufacturers who deal with those countries adopt the metric system as a factory standard, as many have already done. This action would clear the horizon as far as foreign trade is concerned. I for one think that this country is not ready at this time to adopt the metric system. It may come eventually, but for the present the English system is good enough.

New Britain, Conn. W. C. Betz.

Punches and Dies for Making Pepper and Salt Tops

I was much interested in Mr. Mawson's article on page 805. Having had experience on this same job years ago in a small silver shop, I found it interesting to compare the methods, which, with but a few exceptions, were identical. In spite of the fact that these tops were made in very large quantities the high-production compound die was not used. A compound die for a simple round cup is



A SIMPLE BULGING DIE

made almost entirely in a lathe and can be produced as cheaply as the two single-operation dies required. Therefore there seems to be no good excuse for not using a compound die for a job of this sort.

A very important difference in methods was that of bulging the tops. The simple tool shown in the accompanying sketch is much cheaper than the one illustrated in Fig. 9-A, page 805. In operating the die 9-A the halves must be held rigidly while bulging and then be separated to remove the top. The die shown is made of cast iron, machined to the radius desired on the shaker. A piece of rubber is secured to the punch, and the shape of the top is regulated by the amount of rubber used and the force with which it is bulged.

The thread is rolled in a manner similar to that shown, except that the roll is mounted on a hand tool and operated on a T-rest by hand.

A floral design is stamped around the tops, in the space outside the perforations. The design is stamped with five successive blows in a foot press, the operator turning the tops by hand for each stamp. Owing to the stamping of the design, it is necessary to perforate the tops after the stamping and bulging have been done.

Newark, N. J. Gustave A. Remacle.

Machinists Must Not Enlist!

Only a few days of the mobilization of the National Guard have passed yet some facts have already been driven home. Among the guardsmen are many machinists, skilled mechanics. In the aggregate there are several thousand such men who are now under arms. Not a few shops have been more or less seriously crippled through their loss.

It has been the custom in many communities to recruit machinists for batteries and machine-gun platoons. Their mechanical knowledge and training were of especial value in such military units.

In allowing these skilled men to leave the shop for the camp we are making the same mistake that England and France and Germany made at the outbreak of the present European War. In their cases thousands of mechanics were sacrificed in the early days of the struggle, and later on as many such men as possible were withdrawn from the army and sent back to the factories. But the effect of the mistake could not be completely wiped out. Today, in spite of all this experience that stares us in the face, we are making the same mistake.

It is possible that no central authority can interfere in the case of the enlisted guardsmen. But something must be done in connection with new enlistments, particularly if there is a call for 500,000 volunteers. We are short of good mechanics in our shops today, and this situation will grow progressively worse if munition orders are placed and pressure brought to bear to hurry production. A tremendous strain will be put on the machine shops under these conditions, and every mechanic will be needed.

President Wilson or Congress should take immediate action to keep skilled mechanics out of the army. They are more needed elsewhere.

Machinists must not be permitted to enlist!

Courtesy Toward Visitors

There is a lot of room for improvement in the methods of receiving visitors in many shops. Nor is this confined to the smaller places. Some of the larger institutions, with ushers and other appendages, do not leave a good impression with visitors.

Many of the heads of reception rooms are gems of the first water. They are pleasant, diplomatic and thoughtful in the extreme. If the man you want to see is engaged, they make it as pleasant for you as possible and report progress from time to time. Such men are worth more to any concern than they ever get and are a decided addition to that great asset known as good will.

In other cases the reception official is pompous and far from pleasing in any way. He irritates the visitor and increases rather than softens any grouch that may be lurking in the visitor's system. And unfortunately these two types of men seem to reflect the character of those in charge of the business in many cases.

The most annoying characteristic of these men is that they suddenly create an aversion to telling them the life history they demand, before your name goes in to the party you want to see. Perhaps the most exasperating experience is to go to such an office, armed with a perfectly good letter of introduction to the president of the company from one of his friends, and then have the usher open and read it before he decides even to present it. If this is his duty, he should at least be provided with a booth into which he might retire from the gaze of the irate individual who presents the letter.

There are few things that pay better in any business than courtesy and consideration in the treatment of visitors, whether they be ordinary mortals or angels unawares.

Standard-Size Holes--Why?

It is accepted practice in manufacturing machinery to make all holes of standard size and produce variations in fit between these holes and the parts that enter them by varying the sizes of the latter. This is a method of standard-size holes. It has a strong grip in machine-shop practice, but one that is not too strong to question and challenge.

It is difficult to point out the reasons that led to the establishing of this general policy. It may go back to the days when fits were made by actually trying one piece with its mate instead of using standard or limit gages. Be that as it may, today we have these conditions: An enormous and continual expense in buying, making and keeping up reamers, boring cutters and standard arbors because of standard holes; easy methods in changing the dimensions of shafts, studs, pins and spindles throughout the range from driving to running fits.

The disadvantages in these conditions surround the first item. Reamers are among the most expensive of machine-shop small tools—in fact, they are the most expensive, considering the work that they are called upon to do. A standard-size reamer lasts but a very short time, or, put a little differently, will hold its size for only a few holes. Then it must go back to the toolroom for setting up and resharpening. It is this fact that has brought about the popularity of adjustable reamers.

But even these expenses and disadvantages might not seem so serious if the final result—standard holes—actually became a part of the finished machines. However, a standard hole seldom remains standard after it reaches the erecting floor. There come the operations of line reaming, scraping and fitting, which are very apt to change considerably the size of the hole originally produced at a great deal of trouble and expense by using standard reamers.

Along with this comes another feature of design, which is brought about by this practice of making standard holes and varying the size of the fitting members. Very often bearings must be made with caps, because one of the

series is a drive fit and a shaft with a drive-fit section cannot be passed through a standard-size hole. On the other hand, if the holes were varied and the shafts standard in diameter, the shaft could be passed through the running-fit holes to the drive-fit hole and do away with the objection of designing and manufacturing split bearings.

These reasons seem to make out a case for standard-size shafts and varying-size holes which is worthy of serious consideration. The advantages as regards the cost and upkeep of reamers are at once apparent. Reamers of a size to give running fits can be started in use; and, as they wear, they can be reground and stoned to give other variations down to holes small enough for drive fits. This feature should mean the saving of thousands of dollars in the machine shops of this country. Certain disadvantages in design will disappear by the adoption of such a method. Standard arbors will have to be abandoned, of course, with these varying-size holes; but the expansion arbor has come to stay and is a far less delicate tool than the expansion reamer. There is no possible disadvantage in the manufacture of shafts, pins, studs and spindles with varying diameters. Our methods of production lend themselves easily to such a design.

Although this is not a new subject, let us have a free discussion of it.

Some of the Troubles of a Small-Shop Foreman

The letter on page 860 discussing the troubles of a small-shop foreman was printed to call attention to a condition that is as deplorable as it is real. We all know that the problems and tools of the small-shop proprietor are many, but the foreman has his own troubles as well, as indicated in the letter. We also know that success is not to be had by saving five dollars on a clock and wasting twenty-five by not having one; that the foreman is right in saying that you cannot get good men to begin work at 6 a.m. when other shops start at 7 or even later.

No matter how many problems the small-shop proprietor has, and they are many, he must consider the general trade conditions and meet them, if he expects to keep good men in the shop. Good men who can be retained are more of an asset to even a small shop than many seem to realize.

The incident of the brass castings indicates the necessity for some responsible person's being in charge of work, to prevent such occurrences. Here again the cost of error foots up to many times the saving supposed to be effected by letting things run themselves. If the "old man" cannot look after such things, the foreman should be given authority and time to do it. Expensive economy is all too prevalent in small shops as well as in large ones.

Many American employers are showing the truest loyalty by making provision for the welfare of the dependents of such of their employees as are now enlisting or have been mobilized in the National Guard. In some cases wages are being guaranteed for the duration of military service, in other wages and salaries are being guaranteed for a specified number of months or until a certain date. In still others, life-insurance policies are being taken out on the lives of the employees who have gone with their regiments. With hardly an exception, announcement has been made that the positions will be held open until the men return.

Firms who have made these patriotic provisions include almost every kind of business and industry. The American people are duly grateful. Machinery-building firms have not been mentioned in this connection for the very good reason that their employees should not only be discouraged from enlisting, but even prevented from so doing. Every mechanic will be needed in our shops if conditions grow any worse than they are today.

It is reported that one large manufacturer has announced to his employees that the men who are mobilized with or enlist in the National Guard or Army can consider themselves discharged, as their places will not be held open for them and no preference will be given to them should they apply for reëmployment. If this report is true, his act seems to border dangerously on the edge of treason. The announcement itself is like the proverbial fly that buzzes into the ointment.

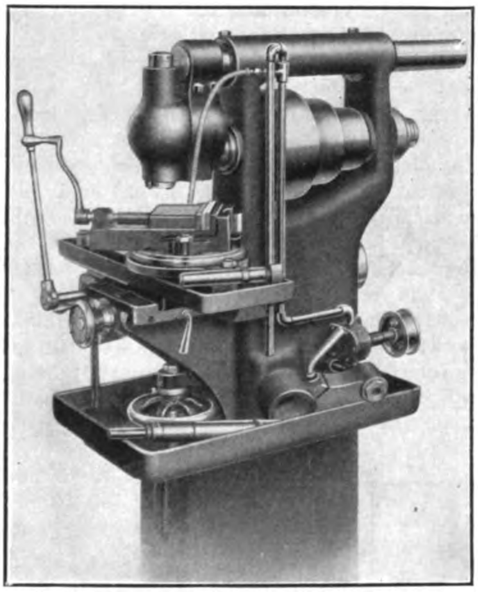
Miller with Vertical and Horizontal Attachment

The hand miller shown represents a combined horizontal and vertical type recently developed by the Bickford Machine Co., Greenfield, Mass.

The rack for the table feed is a quarter-section of a screw and is driven by a worm gear that is designed to reduce backlash and chatter to a minimum. A weight returns the table when the feed is stopped and thereby prevents the cutter from marking the work at the end



MILLER WITH VERTICAL ATTACHMENT

Feed of table (hand or power), 15 in.; crossfeed of saddle, 4½ in.; vertical range of knee, 8 in.; full size of table, 8x23½ in.; greatest distance table to spindle, 8½ in.; largest diameter of cone, 9½ in.; width of driving belt, 3¼ in.; capacity of vise jaw 1¼x5 in., opens 3 in.; floor space, 30x36 in.; weight of machine, 920 lb.; size of box, 21x37x58 in., 26 cu.ft.

of the cut. The feedshaft is extended to take a lever for hand feed. Lever clamping screws are provided, also adjustable graduated collars on both elevating and crossfeed screws.

The vertical attachment, which is readily shipped in place on the machine, has a crucible-steel spindle running in phosphor-bronze bearings and bored for No. 9 Brown & Sharpe taper. The spindle is driven through steel gears by a driveshaft that enters the main spindle of the machine. As will be observed, the attachment when in place becomes a part of the machine, its spindle receiving all the power of the main driving belt.

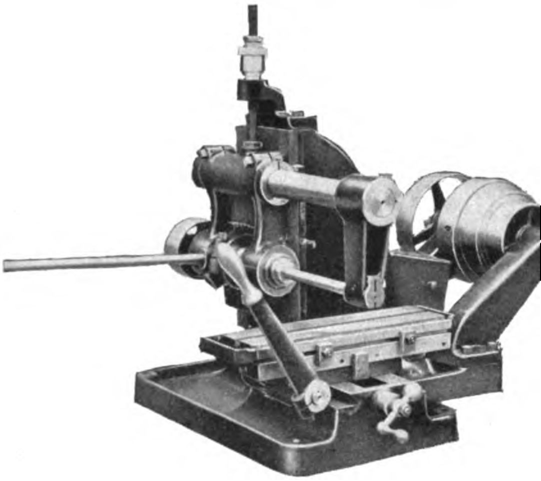
The swivel vise is of simple design, being in reality the addition of a circular plate and ring to the plain vise. For keeping the cutters cool a geared pump is attached to the rear of the machine, the supply tank being in the machine base.

Bench Miller with Adjustabl Head and Overarm

The illustration shows a bench miller of the adju able-head type recently developed by the Morris Mach Tool Co., Cincinnati, Ohio. The machine is also ava able in the column form.

The head slides up and down the column by means o rack and segment operated by a lever that can be pla in two positions to suit the convenience of the operat and is also arranged with micrometer depth gage. It counterbalanced by a weight that is adjustable to ta care of different sizes of cutters or arbors.

The spindle runs in bronze bearings, the front beari being taper and adjustable for wear. The back shaft a runs in bronze bearings. All bearings are arranged



BENCH MILLER

Size of table, 4x15 in.; table feed, 6 in.; vertical travel head, 5 in.; spindle speeds withthree-step cone, 120, 180, 480, 720 and 1,080 r.p.m.; countershaft speed, 360 r.p.m.

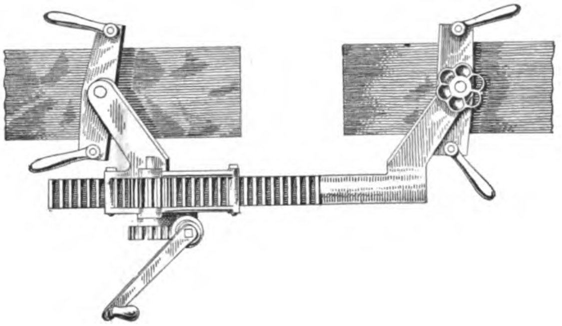
lubrication by the capillary oiling system. Six speeds obtained through the three-step cone and by reversi the pulleys on the end of the spindle and the end of back shaft. The table traverse is operated by a le through rack and pinion. The saddle is fed by a squa thread screw that has a micrometer attachment.

Safety Belt Clamp

In addition to the safety feature of the belt cla shown it is calculated to save time in taking up slack and lacing belts.

The operation of the clamp is made apparent by the lustration. Each side has a swing bolt that enables operator to quickly put the clamps over a slack belt insert the ends of a broken belt; then apply the sw bolts, tighten the clamps and turn the crank until

desired tension is secured. The adjustment is thereby made while the belt is on the pulleys, eliminating all guesswork as to the amount of slack to be taken up. The rack pinion is worm driven to eliminate slippage.



SAFETY BELT CLAMP
Four sizes for belts ranging in width from 1 to 6, 1 to 8, 1 to 10 and 1 to 12 in.

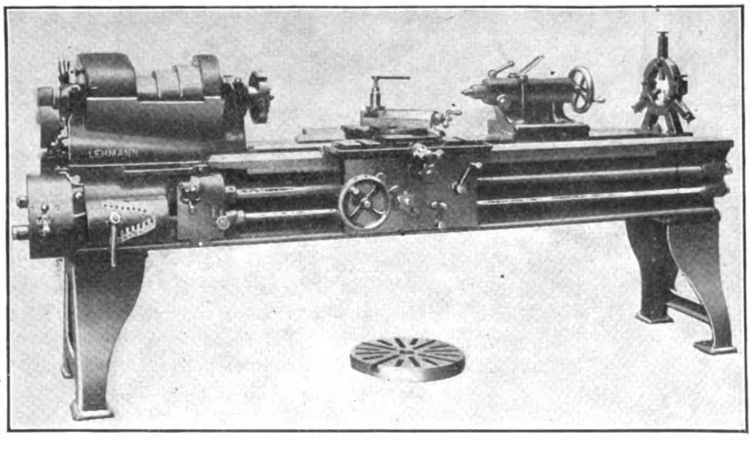
The clamp may be readily separated into two sections, making it easy to carry about and apply to inaccessible drives.

This form of clamp is a recent product of the Cleveland Fabric Belting Co., Cleveland, Ohio.

Quick-Change Engine Lathe

The illustration shows a quick-change engine lathe built by the Lehmann Machine Co., St. Louis, Mo.

The headstock is provided with a three-step cone of a wide face and double back gears that give nine spindle speeds in geometrical progression. The spindle is made of high-carbon steel and ground. Bearings are of phosphor bronze and positively lubricated. They are securely held in place, but may be renewed. End thrust is taken by fiber in contact with steel washers hardened and ground.



QUICK-CHANGE ENGINE LATHE
Swings over shear, 18¼ in.; swings over carriage, 12 in.; takes between centers, 5 ft.; hole through spindle, 1$\frac{5}{16}$ in.; diameter of spindle nose, 2½ in.; number of threads on spindle nose, 6 U.S.S.; cone-pulley diameters, 6$\frac{3}{8}$ in., 8$\frac{1}{3}$ in., 10 in.; width of belt, 3 in.; weight, 3,120 lb.

The bed has chilled ways, is deep and wide and is braced by large crossribs. All bearings fastened to the bed are doweled into position on planed bosses. The carriage is provided with an oil trough that returns cutting lubricant inside of the V's. Shear wipers fastened to the carriage keep the V's lubricated and clean. The apron gives double support for studs and a double bearing for running shafts. The lead screw and feed rod have bearings in the apron. All gears and pinions except friction gears are of steel, and the studs are hardened and ground. A safety device prevents engagement of the feed rod and the lead screw at the same time.

The tailstock is clamped to the bed by bolts brought up to the top of the barrel convenient for the operator. The spindle is large and is provided with an improved device for locking. The lead screw is of high-carbon steel with a four-pitch Acme thread. It is provided with a ball thrust.

New Cutting-Tool Alloy

A new alloy for cutting-tool purposes is being introduced by Darwin & Milner, Ltd., Sheffield, England. With this alloy no heat-treatment is needed, the material being ready for use after grinding. It is cast in bars of any section, those that were used in a recent demonstration being from 2 in. square down to ¼x$\frac{5}{16}$ in.

The same firm is said to be making experiments with a view to the direct casting of such things as milling cutters. Another application of the material proposed is for motor valves. The alloy is put forward as a substitute for the best high-speed steel, and its composition includes no vanadium, tungsten, molybdenum or cobalt. It is cast in iron or sand molds, iron giving slightly better results. It is said to be much tougher than stellite.

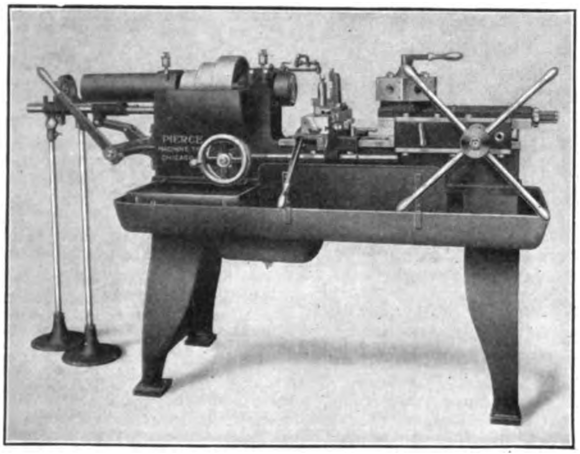
To demonstrate the material a bar of chrome-nickel steel was turned in a 24-in. lathe, the bar turned containing, according to the analysis given: Carbon, 0.32 per cent.; manganese, 0.63 per cent.; chromium, 1.17 per cent.; nickel, 3.28 per cent. A tool of this material 1¼ in. square ran for 8 min. against a well-known high-speed steel tool, which ran for 3 min., the cutting speed being 100 ft. per min. and the cut $\frac{3}{32}$ in. deep by $\frac{1}{32}$ in. feed. In subsequent demonstrations the cuts were at 45 ft. per min., $\frac{1}{16}$ in. deep by ¼ in. feed, the tool running for 7⅓ min. and remaining in good condition at the end. A 2-in. square tool was run at 35 ft. per min., $\frac{3}{16}$ in. deep by ⅛ in. feed; a ½-in. square tool at 45 ft. per min. with a cut $\frac{3}{32}$ in. deep by $\frac{1}{16}$ in. feed; and a tool ¼x$\frac{5}{16}$ in., without tool holder, was used at 50 ft. per min. with a cut about $\frac{1}{32}$ in. deep by $\frac{1}{16}$ in. feed.

The demonstration altogether took about two hours, during which time two 1¼-in. square section bars of the new material were cast in iron molds. When fairly cool one bar was at once ground to shape on an emery wheel, finishing on an ordinary grindstone. It was then for a time cooled in an air blast, so that the workmen could handle it, after which it was placed in the lathe and run for about 13 min. at 47 ft. per min. on the chrome-nickel steel bar mentioned, the cut being $\frac{3}{16}$ in. deep by $\frac{1}{16}$ in. feed, altered at about halfway to $\frac{1}{32}$ in. deep by $\frac{1}{32}$ in. feed. The tool was in good condition at end of test.

Hand Screw Machine with Wire Feed

The hand screw machine shown is of similar type to that illustrated on page 1093, with the addition of wire feed and automatic chuck.

The machine is made by the Pierce Machine Tool Co., Chicago, Ill., and requires no further description as to



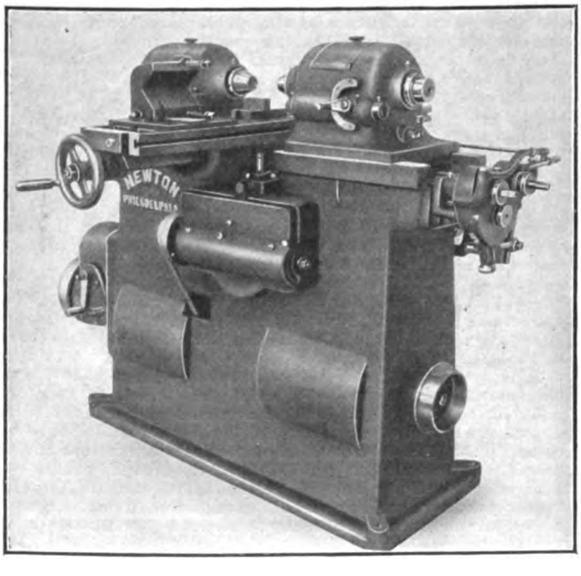
HAND SCREW MACHINE WITH WIRE FEED

Capacity automatic chuck, round, $1\frac{1}{16}$ in.; capacity automatic chuck, square, $\frac{3}{4}$ in.; capacity automatic chuck, hexagon, $\frac{15}{16}$ in.; capacity threaded work on soft steel, $\frac{5}{8}$ in. U.S.S.; capacity pipe threads in brass, up to $1\frac{1}{16}$ in.; capacity drilling in soft steel, $\frac{3}{4}$ in..

design and construction than that given in the previously mentioned article.

Duplex Slot Miller

The illustration shows a double-spindle slot miller built by the Newton Machine Tool Works, Inc., Philadelphia, Penn., and designed for a wide range of work.



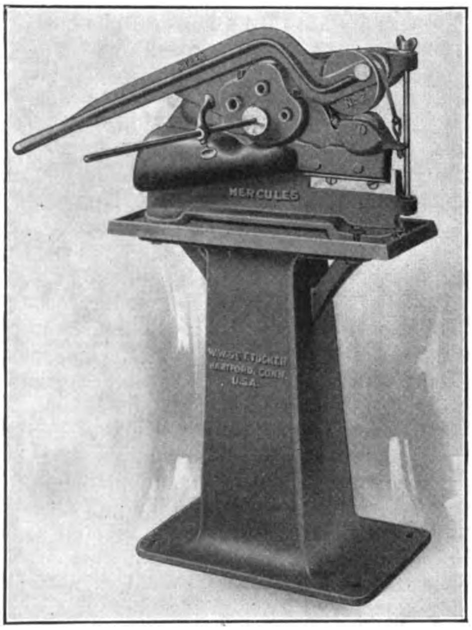
DUPLEX SLOT MILLER

Table feed, per stroke, $\frac{1}{16}$ in. maximum; work table, 44x9 in.; maximum capacity, 4-in. shafts; keyseat capacity, $\frac{1}{8}$ to $\frac{1}{4}$ in.; maximum distance between spindles, 10 in.; driving pulley, 10 in. in diameter; countershaft, 20 in. in diameter, weight, 3,000 lb.

The spindles are provided with double taper bearings fitted with draw-in collets for holding the slot-milling cutters. The spindle heads have automatic feed with safety release when milling cotter holes. Four changes of geared spindle speeds are available without changing gears. High spindle speeds are obtained by open belt and slow speeds through the back gears. The feeds for the work table are either continuous for long splines or reverse automatically for cottering.

Bar-Iron Cutter and Shear

The illustration shows an iron cutter and shear built by W. A. & C. F. Tucker, Hartford, Conn. This machine is made in six sizes to cut round iron up to $\frac{3}{4}$ in. and to shear flat stock up to $\frac{5}{16}$ in. thick. The cutters



ROD CUTTER AND SHEAR

for the round stock are in the shape of bushings, made of tool steel and held in place by setscrews. The shear blades are of wrought iron, tool-steel faced. The direction of the shear cut tends to draw the stock into the shear. An adjustable length gage is provided for the bar-stock cutters. The machine is also built without the bar-stock cutters, as a flat-stock shear.

Direct-Current Motors of the Lower Horsepowers

To meet the increasing demand for direct-current motors of the smaller horsepowers for direct connection and drive of all kinds of industrial machinery, machine tools and the many motor applications requiring a low-power compact motor, the C. & C. Electric and Mfg. Co., Garwood, N. J., has developed a new line.

The new motors, known as the Type IB, are of bi-polar type, with interpoles, and can be furnished in ratings up to 10 hp. in either the shunt or compound wound. For a general manufacturer's drives, as machine tools and other industrial machinery, the characteristics of the shunt-wound motor are the most desirable.

Master Mechanics' Convention

The annual convention of the American Railway Master Mechanics' Association was held at Atlantic City, N. J., June 19 to 21. While there were more exhibits than in 1915, the number of machine tools and appliances was less and the total fell below that of 1914. The general appearance of all exhibits was more attractive, however, and the attendance was good. Some of the few machine firms represented were new comers at this convention. Among the exhibitors of machine tools or appliances were:

E. C. Atkins & Co., Indianapolis, Ind.; C. H. Besly & Co., Chicago, Ill.; S. F. Bowser & Co., Fort Wayne, Ind.; Carbic Manufacturing Co., Duluth, Minn.; Carborundum Co., Niagara Falls, N. Y.; Chicago Pneumatic Tool Co., Chicago, Ill.; Clipper Belt Lacer Co., Grand Rapids, Mich.; Crucible Steel Co. of America, Pittsburgh, Penn.; Davis Machine Tool Co., Rochester, N. Y.; Dixon Crucible Co., Jersey City, N. J.; Fairbanks, Morse & Co., Chicago, Ill.; General Electric Co.. Schenectady, N. Y.; Gibb Instrument Co., Pittsburgh, Penn.; Gilbert & Barker Co., Springfield, Mass.; Goldschmidt Thermit Co., New York City; Greene, Tweed & Co., New York City; Greenfield Tap and Die Corporation, Greenfield, Mass.; Edwin Harrington Son & Co., Philadelphia, Penn.; Independent Pneumatic Tool Co., Chicago, Ill.; Ingersoll-Rand Co., New York City; Keller Mechanical Engraving Co., Brooklyn, N. Y.; Keller Pneumatic Tool Co., Chicago, Ill.; R. D. Nuttall Co., Pittsburgh, Penn.; Nutter & Barnes Co., Hinsdale, N. H.; Oxweld Railroad Service Co., New York City; Quigley Furnace Specialties Co., New York City; Reliance Electric and Engineering Co., Cleveland, Ohio; Wm. Sellers & Co., Philadelphia, Penn.; Simonds Manufacturing Co., Fitchburg, Mass.; United Engineering and Foundry Co., Pittsburgh, Penn.; Warner & Swasey Co., Cleveland, Ohio; Watson-Stillman Co., New York City; Westinghouse Electric and Manufacturing Co., Pittsburgh, Penn.; Wilson Welder and Metals Co., New York City; Yale & Towne Manufacturing Co., New York City.

A gratifying feature of the meetings was the interest shown in the paper by F. O. Wells on the "Standardization of Screw Threads." This association, it will be remembered, was one of the pioneers in the adoption of standards of various kinds, and the screw-thread question is likely to receive careful consideration at the hands of its members. Mr. Wells pointed out the sources of error, the necessity for tolerances that are commercial yet sufficiently accurate for the work in hand, as well as the means for measuring the threads properly—that is, at the pitch diameter.

NEW PUBLICATIONS

FORGING OF IRON AND STEEL—By William A. Richards. Two hundred and thirteen 5x8-in. pages; 237 illustrations; appendix; indexed; cloth bound. D. Van Nostrand Co., New York City. Price, $1.50.

This textbook is intended for use in colleges, secondary schools and the shop. Its author has had an extensive experience in teaching forging and smithwork. As a result he has gathered together in this book statements and illustrations of principles rather than specific exercises.

The first chapter is historical in nature and, while interesting, is not pertinent to the purpose of the book and might well have been omitted. The second chapter deals with iron and steel in their different forms, briefly indicating how they are produced. The third chapter shows the equipment needed for forging, and the fourth takes up the matter of fuel and fire.

With Chapter V begin the various forging processes, running through to Chapter X. The headings are: Drawing Down and Upsetting; Bending and Twisting; Splitting, Punching and Riveting; The Use of Blacksmith Tools; Welding. Then follow two chapters that hardly seem to belong in a textbook of this kind. Chapter X deals with electric, autogenous and thermit welding. All three processes are special in character, requiring peculiar, expensive equipment. Furthermore, they are not likely to be met with by the ordinary graduate of a course in forging and smithing. Chapter XI is in the same class, as it deals with brazing, a very specialized process in metal working.

Chapters XII and XIII take up tool steel and high-speed tool steel, giving much helpful information in regard to their treatment and working. Chapter XIV is devoted to art ironwork and Chapter XV to steam and power hammers. The final chapter deals with the calculations of such shapes as are commonly met with in blacksmithing. An appendix of 33 pages gives a course of instruction that the author has used with high-school and college pupils.

Taken all in all, the book seems well thought out and prepared, with the exception of some matter that seems unnecessary. An unfortunate selection of the type of illustrations mars the otherwise pleasing appearance of the pages.

SUCCESS IN THE SMALL SHOP—By John H. Van Deventer. One hundred and thirty-six 9x12-in. pages; illustrated; indexed; cloth bound. Published by the "American Machinist," New York City. Price, with one year's subscription to the "American Machinist," $4.75.

Reviewed by Dexter S. Kimball*

This interesting book presents in collected form fifty articles and a part of the discussion they called forth in the "American Machinist" during the years 1914-16. These articles were the results of a definite idea—namely, showing the place and possibility of the small shop in the manufacturing field. It was their purpose also to analyze the situation regarding small shops, to find out their weaknesses and their strong points and to offer suggestions and criticisms that would be helpful and strengthening.

Included in the collection are discussions on financing, accounting, management, machine equipment, small-tool equipment, selection of work, helpful devices, shop kinks and methods, etc., all with reference primarily to the small shop. The discussion and comments that were evoked throw many interesting and amusing sidelights on life in the small shop. In presenting this material in collected form it is the hope of the editors of the "American Machinist" that the book will be found of service not only to the owner and manager of the small shop, but also to men in larger shops where departments are often so organized as to present problems much the same as those of their little neighbors.

Some of the articles are of peculiar interest. Thus the first one, entitled "The Future of the Small Shop," contains some detailed historical data bearing on the probable future of the small shop. The argument presented that there will always be room for the small shop in spite of the higher efficiency of the large shop is worth reading. It is of interest also to read that 80 per cent. of all American manufacturing plants are small ones and that in the machine-tool using industries there are 15,000 small shops employing less than 20 men to 1,200 large shops employing more than 250 men. One is led to believe that, after all, the complete consolidation of industry is some distance away. There are many other exceptionally good articles and some on the management of small shops that are worth reading even for a man who is managing a large enterprise.

The object of the book is most praiseworthy. All will agree that anything that will foster individual effort, that will assist in retaining and increasing widespread ownership of industry and that will assist the little fellow to retain his foothold in the industrial field is commendable. The small shop is proverbially less efficient than the large shop. But a perusal of this volume will show that much of this difficulty often arises from lack of financial and manufacturing knowledge as much as from inherent and unalterable circumstances. The treatment of specialization, interest and depreciation, manufacturing expense, inventory, profits and kindred subjects as applied to the small shop is therefore highly pertinent and important, though sometimes written in a jocular manner with many anecdotes to illustrate the points presented.

To those who, like the writer, served an apprenticeship in a small shop in the real old-fashioned way the book will awaken memories of many interesting people. There was a

*Professor, Machine Design and Construction, Sibley College, Cornell University.

picturesqueness about the old-fashioned small shop that has been lost in the larger, more modern and specialized factory. The many character sketches scattered throughout the book cannot fail to remind older men very vividly of the days when trades still had "mysteries" and interchangeable systems were unknown. There was some roughness, but also a great deal of kindliness in the old shops, and "boss" and workman were much closer to each other than they ever can be in the larger modern plant and in fact than they are in most small plants of today. True, these old shops were not efficient, and their successors of today may not be so efficient as they should be. But the small shop certainly contains some things that are worth saving. It stands for individuality and independence. This book should be an aid toward the betterment of the chances for success of the small manufacturer.

The book is attractively bound, and the subject matter is fully illustrated as it was in its original appearance in the "American Machinist."

PERSONALS

D. A. Urquart, until recently foreman of the screw-machine department of the Brown & Sharpe Mfg. Co., has become superintendent of the Union Twist Drill Co., succeeding A. N. Goddard, recently resigned.

F. A. Robinson, for several years a member of the executive force of the Becker Milling Machine Co., Hyde Park, Mass., has been appointed advertising manager, succeeding George Y. Young, recently resigned.

Frank O. Wells, president of Wells Bros. & Co., Greenfield, Mass., has also been elected president of the F. E. Wells and Sons Co., succeeding F. E. Wells who has relinquished active control after fifty years' association with the business.

J. F. Tinsley has accepted the position of assistant superintendent of the Crompton & Knowles Loom Works, Worcester, Mass., having resigned the superintendency of the South Works of the American Steel and Wire Co., Worcester, Mass.

OBITUARY

John D. Hughes, superintendent of the Putnam Machine Co., Fitchburg, Mass., and for a number of years connected with the Bullard Machine Tool Co., Bridgeport, Conn., in various capacities, died on June 15 as the result of an automobile accident. Mr. Hughes was a native of Bridgeport and was but 42 years of age.

George Gilmour, well-known in mechanical circles through his constructive work in accident prevention as head of the engineering and inspection department of the Travelers Insurance Co., died at his home in Brooklyn, N. Y., on June 16. Mr. Gilmour was born in Petrograd, Russia, Jan. 5, 1865, of Scotch parents, his father being chief naval constructor for the Russian government. The son learned the trade of mechanical engineer with John Elder & Co., shipbuilders and engineers, of Glasgow, Scotland. After learning his trade he went to South America, where he worked for a time. Returning by way of Panama he was engaged by French engineers to take charge of the mechanical department of the work on the Panama Canal. Following a period of service on the Isthmus, he became an engineer for the Atlas Line of mail steamers and, when the West India Improvements Co. bought the Jamaica Government Ry., he was chosen master mechanic of the system. The Jamaica Light and Power Co. also had his services as superintendent of motive power and later as consulting engineer. After eight years spent in Jamaica, Mr. Gilmour was appointed mechanical engineer for the New York Telephone Co. and he worked in New York eight years, resigning in 1905 to become chief engineer for the Travelers Insurance Co.

BUSINESS ITEMS

Edward G. Brown, 5, 6, 7 Great Hampton St., Birmingham, England, wants agencies in Great Britain for machine-shop equipment.

The Capital Stock of the Cincinnati Screw Co., Twightwee, Ohio, has been increased to $200,000. Additional large orders have been placed for equipment.

The Federal Tool & Stamping Co. has been organized at Zeeland, Mich., to do metal stamping, tool designing and light machine work. The officers are R. B. Somers, president; J. L. De Glopper, vice-president; F. L. Jerome, secretary; J. S. Van Volkenburgh, treasurer and manager.

Joseph H. Roach & Co., Inc., was organized and has purchased a foundry and machine shop in Bridgeport, Penn., formerly engaged in the manufacture of Wilkinson stokers. In addition to the manufacture of stokers the new firm will conduct a general foundry and machine shop business. Joseph H. Roach, president and founder, was Philadelphia manager of the Hoover, Owens, Rentschler Co.

The Vulcan Trading Corporation, a consolidation of the businesses of Archibald J. Wolfe, London and Lancashire Trading Co. and F. Velthardt, has been organized in New York City, to carry on a general exporting business, specializing in iron, steel and machinery. Mr. Wolfe, who will be in charge of the Russian and machinery departments, was for a number of years connected with the United States Department of Commerce, as Commercial Agent, and later Russian representative of the U. S. Steel Products Co.

CATALOGS WANTED

J. B. Giovanoli, Supervisor of Tools, Continental Motors Co., Muskegon, Mich., would like to receive catalogs of machines and tools used in the manufacture of gasoline automobile motors.

TRADE CATALOGS

Herringbone Gears. Fawcus Machine Co., Pittsburgh, Penn. Catalog. Pp. 16, 9x12 in.; illustrated.

Hilo Black Enamels and Japans. Moller & Schumann Co., Marcy and Fushhing Ave., Brooklyn, N. Y. Bulletin No. 1. Pp. 14. 5x8 in.; illustrated.

Engine Lathes. Worcester Lathe Co., 68 Prescott St., Worcester, Mass. Set of circulars illustrating and describing the different sizes of lathes built by this company.

Chain Belt Traveling Water Screens. Chain Belt Co., Milwaukee, Wis. Bulletin No. 64. Pp. 8, 6x9 in.; illustrated. This describes water screens designed primarily to remove refuse and foreign material from water before it enters power and industrial plants, etc., requiring large quantities of clean water.

FORTHCOMING MEETINGS

American Society for Testing Materials. Annual meeting June 27 to July 1, 1916, Hotel Traymore, Atlantic City, N. J. Edgar Warburg, secretary, University of Pennsylvania, Philadelphia, Penn.

American Foundrymen's Association and American Institute of Metals. Annual meeting, September 11-16, Cleveland, Ohio, A. O. Backert, secretary, American Foundrymen's Association, Cleveland, Ohio.

American Society of Mechanical Engineers. Monthly meeting first Tuesday. Calvin W. Rice, secretary, 29 West Thirty-ninth St., New York City.

Boston Branch National Metal Trades Association. Monthly meeting on first Wednesday of each month, Young's Hotel. W. W. Poole, secretary, 40 Central St., Boston, Mass.

Providence Association of Mechanical Engineers. Monthly meeting fourth Wednesday each month. J. A. Brooks, secretary, Brown University, Providence, R. I.

New England Foundrymen's Association. Regular meeting second Wednesday of each month. Exchange Club, Boston, Mass. Fred F. Stockwell, 205 Broadway, Cambridgeport, Mass.

Engineers' Society of Western Pennsylvania. Monthly meeting third Tuesday; section meeting, first Tuesday. Elmer K. Hiles, secretary, Oliver Building, Pittsburgh, Penn.

Rochester Society of Technical Draftsmen. Monthly meeting, last Thursday. O. L. Angevine, Jr., secretary, 857 Genesee St., Rochester, N. Y.

Superintendents' and Foremen's Club of Cleveland. Monthly meeting third Saturday. Philip Frankel, secretary, 310 New England Building, Cleveland, Ohio.

Western Society of Engineers, Chicago, Ill. Regular meeting first Wednesday evening of each month, excepting July and August. J. H. Warder, secretary, 1785 Monadnock Block, Chicago, Ill.

Philadelphia Foundrymen's Association. Meetings first Wednesday of each month. Manufacturers' Club, Philadelphia, Penn. Howard Evans, secretary, Pier 45 North, Philadelphia, Penn.

Technical League of America. Regular meeting second Friday of each month. Oscar S. Teale, secretary, 35 Broadway, New York, N. Y.

Prices--Materials and Supplies

IRON AND STEEL

Pig Iron—Quotations were current as follows at the points and dates indicated:

	June 23, 1916	One Month Ago	One Year Ago
No. 2 Southern Foundry, Birmingham	$14.50	$15.00	$9.75
No. 2 X Northern Foundry, New York	19.75	20.75	14.25

The S-S-E Co., 2300 Chestnut, Philadelphia, Penn., is having plans prepared for the construction of a 1-story, 200x100-ft. brick and concrete automobile factory at Erie Ave. and B St., Philadelphia. V. L. Emerson is Gen. Mgr.

The Sweeten Automobile Co., Philadelphia, Penn., has awarded the contract for the construction of an addition to its service station at 3430 Chestnut St.

The contract has been awarded for the construction of a 2- and 3-story, 100x156-ft. garage for the Albion Hotel, Baltimore, Md.

An automobile repair shop will be established by the Auto Appliance Manufacturing Co., 11-13 East 21st St., Baltimore, Md.

A 1-story addition will be built to the iron and brass foundry of the Caroline Foundry Co., 723 South Caroline St., Baltimore, Md.

The Cityco Realty Co., 2 East Lexington St., Baltimore, Md., plans to build a 45x250-ft. garage.

The contract has been awarded for the construction of a plant at Laney's Lane and Pennsylvania R.R., Baltimore, Md., for the Hess Steel Co. Estimated cost, $100,000.

SOUTHERN STATES

The Slab Fork Coal Co., Slab Fork, W. Va., plans to construct a machine shop and will be in the market for 40-in. engine lathe, shaper and Hyd press.

The Atlanta Plow Co. plans to construct additions to its plant on Howell Mill Rd., Atlanta, Ga.

The Studebaker Corporation, Brush and Piquette St., Detroit, Mich., plans to construct a plant at New Orleans, La.

The Chattanooga Machinery Co., Chattanooga, Tenn., plans to construct a factory.

The Paducah Automobile and Manufacturing Co., Paducah, Ky., recently incorporated with $25,000 capital stock, plans to construct a factory for the manufacture of automobile parts.

MIDDLE WEST

The Corcoran Manufacturing Co., recently incorporated at Cincinnati, Ohio, will establish a factory on Winton Pl., Cincinnati, for the manufacture of automobile bodies, hoods, fenders, etc. L. Corcoran is Pres.

The Hooven-Owens-Rentschler Co., manufacturer of power engines, Hamilton, Ohio, plans to enlarge its iron foundry.

The National Tube Co. has started work on the construction of a blooming mill at Lorain, Ohio. Noted June 8.

The Spicer Manufacturing Co., foundry and machine works, New Philadelphia, Ohio, plans to rebuild its plant, recently destroyed by fire. R. T. Norning is Mgr. Noted May 25.

The Phillips Sheet and Tin Plate Co., Steubenville, Ohio, plans to construct an addition to its plant. Estimated cost, $6,000. D. M. Weir is Vice-Pres.

The Pressed Steel Products Co., Youngstown, Ohio, plans to construct an addition to be used for the manufacture of steel drums.

The contract has been awarded for the construction of a 1-story addition to the plant of the Kuhlman Car Co., East 140th St., Cleveland, Ohio. Noted May 18.

The Sanitary Tinning Co., manufacturer of general hardware, etc., plans to construct a factory on East 93rd St., near Way Ave., Cleveland, Ohio. Estimated cost, $50,000. A. J. Miller is Pres.

The Mark Manufacturing Co. will construct a new steel mill at Indiana Harbor, Ind. Estimated cost, $5,000,000.

The Studebaker Corporation, Brush and Piquette St., Detroit, Mich., contemplates the construction of a plant at La Fayette, Ind.

The Albion Bolt Co., Albion, Mich., recently incorporated with $10,000 capital stock, will establish a factory for the manufacture of nuts and bolts. M. Merriam is Pres.

The Chevrolet Motor Co., has awarded the contract for the construction of a factory at Bay City, Mich.

The Superior Steel Casting Co. will construct a factory at Benton Harbor, Mich.

The Detroit Brass Works, Detroit, Mich., has awarded the contract for the construction of a 2-story factory. Noted June 1.

The Ford Motor Car Co., Detroit, Mich., plans to construct a 4-story factory at 4325 Broadway, Detroit. Estimated cost, $60,000.

The Motor Products Corporation, 762 Woodward Ave., Detroit, Mich., manufacturer of motorcycles, plans to construct a factory.

Plans are being considered by the Alter Motor Car Co., Essexville, Mich., for the construction of a factory. F. M. Woodward is Gen. Sales Mgr.

Fire recently destroyed the main buildings of the Johnston Bros.' Boiler Works, Ferrysburg, Mich. Loss, $150,000.

The Dort Motor Car Co., Flint, Mich., plans to construct a factory. Estimated cost, $60,000.

The Acme Universal Joint Co., Kalamazoo, Mich., plans to construct a plant at Kalamazoo for the manufacture of auto joints.

The Baldwin Manufacturing Co., manufacturer of standing grain thresher, Sparta, Mich., desires catalogs and price lists from manufacturers of machinery and iron and steel. W. H. Hall is Pur. Agt.

The Moore Bros. Stove Works, Joliet, Ill., will build an addition to its factory on Franklin St.

Work has been started on the construction of an addition to the plant of the Lyon Metallic Manufacturing Co., Montgomery, Ill.

The T. A. Cummings Foundry Co., 1354 Cortland St., Chicago, Ill., will build a 1-story addition to its plant.

The Sasgen Derrick Co., 3101 Grand Ave., Chicago, Ill., has awarded the contract for the construction of an addition to its plant. Estimated cost, $18,000. Noted June 22.

The Western Iron Co., 1208 Borland Bldg., Chicago, Ill., granted permit to build a 1-story garage at 4906-08 North Clark St., Chicago. Estimated cost, $10,000. N. Buck, Arch.

The John Obenberger Forge Co. will construct a forge and machine shop at 63rd and Lapham St., Milwaukee, Wis.

The contract has been awarded for the construction of a factory for the George H. Smith Steel Casting Co., Madison St., Milwaukee, Wis.

Plans have been prepared by C. J. Keller, Arch., for the construction of a factory on Oregon St., Milwaukee, Wis., for the General Welding and Manufacturing Co.

The Ward Manufacturing Co., manufacturer of motorcycles and bicycles, plans to construct an addition to its plant at 18th St. and Martin Ave., Sheboygan, Wis.

Hugh E. Jones and Frank Drinolka, Waupaca, Wis., plans to construct a garage at Waupaca.

The Overland-Wisconsin Co., Milwaukee, Wis., plans to construct a distributing and service station at McIndoe and 1st St., Wausau, Wis. Estimated cost, $40,000.

WEST OF THE MISSISSIPPI

A 3-story addition is being built to the plant of the Dexter Co., Fairfield, Iowa, manufacturer of washing machines.

The Consumers Twine and Machinery Co. plans to improve its plant at Sioux City, Iowa. Estimated cost, $50,000.

The Mercantile Warehouse Co. will construct a garage at Waterloo, Iowa. Estimated cost, $35,000.

The Mareen & Johnson Machine Co. is constructing a 1-story machine shop at 700 44th Ave., N., Minneapolis, Minn. Estimated cost, $8,000.

The Smith Novelty and Toy Manufacturing Co. plans to construct a factory in Midway District, St. Paul, Minn.

The Four S Razor Co. plans to construct a factory at Hutchinson, Kan.

The Cooper Foundry Co., Atchison, Kan., recently incorporated, plans to establish a foundry. Charles Cooper, St. Joseph, Mo., is interested.

Armour & Co. plans to construct a machine shop at South Omaha, Neb.

The Missouri Meerschaum Pipe Co. plans to construct an addition to its plant at Owensville, Mo. Estimated cost, $10,-00.

J. E. and Ross Lee and J. F. Greer, Springfield, Mo., plans to construct a foundry and machine shop at Yellville, Ark.

The contract has been awarded for the construction of a garage and salesroom at Abilene, Tex., for David S. Castle, 29 Radford Bldg., Abilene. Estimated cost, $15,000.

W. C. Durant plans to construct an assembling plant at Ft. Worth, Tex. Estimated cost, $690,000.

Charles E. Brown and H. D. Bruce plans to construct a plant at Lawton, Okla., for the manufacture of mining machinery.

WESTERN STATES

The American Coin Register Co., 1706 Broadway, Oakland, Calif., has awarded the contract for the construction of a 2-story factory at Emeryville, Calif.

Plans are being prepared for the construction of a 50x117-ftfl garage on Main St., Los Angeles, Calif., for Gregg & Twiss.

T. J. Wisecarver plans to construct a 2-story garage at Modesto, Calif. Estimated cost, $16,000.

CANADA

The Grand Trunk Ry. plans to construct a roundhouse, machine shop, etc., at Lindsay, Ont. Estimated cost, $20,000. J. D. McMillan, Belleville, Ont., Acting Supt.

The Algoma Steel Co. is constructing a plant at Steelton, Ont. Estimated cost, $12,000.

The Sheet Metal Products Co. of Canada, Ltd., 199 River St., Toronto, Ont., has awarded the contract for the construction of a plant at Toronto. Estimated cost, $6,000.

The Automatic Thresher and Machine Co., Ltd., recently incorporated, plans to construct a plant at Calgary, Alta.

FOREIGN OPPORTUNITIES

William Hall, Ltd., Alma Works, Sheffield, England, is open to purchase continuously large quantities of twist drills, steel jobbers lengths. Price lists, discount and cash terms are desired.

GENERAL MANUFACTURING

NEW ENGLAND STATES

The Sears-Roebuck Co., Chicago, Ill., contemplates constructing a 4-story factory at Portsmouth, N. H., for the manufacture of shoes.

The John T. Slack Corporation, manufacturer of shoddy, plans to construct a 1-story, 20x200-ft. factory at Springfield, Vt.

The Smith Paper Co. has awarded the contract for the construction of an addition to its factory at Lee, Mass.

The Lowell Textile Co. plans to construct a 2-story mill at North Chelmsford, Mass.

The contract has been awarded for the construction of a 2-story addition to the factory of Edwin Bartlett, manufacturer of cotton warps, at North Oxford, Mass.

The contract has been awarded for the construction of a factory on Chandler St., Worcester, Mass., for Bickford & Sweet, 60 King St., manufacturer of slippers. Estimated cost, $25,000. Noted Feb. 17.

The International Braid Co. has awarded the contract for the construction of a 4-story factory at its Elmwood mills at Daboll and Mawney St., Providence, R. I. Estimated cost, $60,000. Noted June 22.

MIDDLE ATLANTIC STATES

The Auburn Button Co., Auburn, N. Y., has awarded the contract for the construction of a 1-story, 45x200-ft. shoe factory.

The contract has been awarded for the construction of a plant for the manufacture of nitric acid for the Contact Process Co., Buffalo, N. Y., manufacturer of chemicals. Estimated cost, $135,000. Noted Feb. 10.

Plans are being prepared for the construction of a 3-story, 80x300-ft. reinforced-concrete factory at Elmwood Ave. and Erie R.R., Buffalo, N. Y., for the Kittinger Furniture Co.

The Chautauqua Worsted Mills, Lisler Ave. and Erie R.R., Falconer, N. Y., has awarded the contract for additions to its plant. Estimated cost, $50,000.

The Little Falls Felt Shoe Co., Little Falls, N. Y., has awarded the contract for the construction of a factory.

The contract has been awarded for the construction of a 4-story, 100x230-ft. factory building at Anabel Ave. and Creek St., Long Island City, N. Y. (Borough of Queens), for the Degnon Realty and Improvement Co., 3 East 42nd St., Manhattan, to be leased by the Kindel Bed Co., Chicago, Ill. Estimated cost, $125,000. Noted June 8.

Plans are being considered by the Burlington Silk Mills, Burlington, N. J., for an addition to its factory.

The contract has been awarded for the construction of a 1-story adition to the plant of the B. F. Boyer Co., Camden, N. J., manufacturer of worsted yarns. Noted June 22.

Press reports state that the Whitney Glass Works, Glassboro, N. J., plans to construct additions to its plant on Sewell St.

Plans are being considered by Betz & Gross, Dillsburg, Penn., for the construction of a hosiery mill at Dillsburg.

Press reports state that a plant will be constructed at Marcus Hook, Penn., by the General Chemical Co., 25 Broad St., New York, N. Y.

The William Cramp and Sons Ship and Engine Building Co., Bench and Ball St., Philadelphia, Penn., contemplates enlarging its plant on Pettys Island.

According to press reports a 5-story addition will be built to the factory of the Ferris Shoe Co., Janney and Weikel St., Philadelphia, Penn. Albert B. Groves, 314 North 4th St., St. Louis, Mo., is Arch.

The contract has been awarded for the construction of a 2-story factory on Bodine St., Philadelphia, Penn., for George C. Mellor, manufacturer of pianos. Estimated cost, $12,000.

Plans have been prepared by Charles W. Denny, Arch., Hale Bldg., Philadelphia, Penn., for the construction of a 4-story addition to the factory of the National Drug Co., 4679 Stenton Ave., Philadelphia.

The contract has been awarded for the construction of an 8-story building on Sandusky St., Pittsburgh, Penn., for the United State Rubber Co. Estimated cost, $125,000.

The contract has been awarded for the construction of an addition to the plant of the Rich Woolen Mills, Woolrich, Penn. Noted May 4 and 18.

The American Manganese Steel Co. plans to construct an addition to its plant at New Castle, Del.

The Baltimore Enamel and Novelty Co., Baltimore, Md., plans to construct a factory on Allen St.

SOUTHERN STATES

A. C. Ernst of the Viscoe Co., Marcus Hook, Penn., plans to construct a silk mill at Roanoke, Va. Estimated cost, $1,000,000.

The Blue Ridge Brokerage Co. plans to construct a cold-storage plant at Greenville, S. C.

T. J. McNamara, formerly superintendent of the Lanett Bleachery and Dye Works, Lanett, Ala., plans to construct a bleachery and dye plant at Atlanta, Ga. Estimated cost between $10,000 and $20,000.

According to press reports Armour & Co. plans to to construct a packing plant near Talleyrand Ave., Jacksonville, Fla. H. B. Minimum is Mgr.

Fire recently destroyed the packing plant of Lee & Edwards, Thonotosassa, Fla.

W. H. Sullivan of the Great Southern Lumber Co., Bogalusa, La., plans to construct a paper mill at Bogalusa. Estimated cost, $1,000,000.

The Mente Bay Co., New Orleans, La., manufacturer of tires, plans to enlarge and improve its plant on Montegut St.

The Compressed Inner Tube Co., manufacturer of a solid rubber device for use inside of automobile tires, plans to construct a factory at Louisville, Ky. S. S. Bush and Samuel A. Culbertson, Columbia Bldg., Louisville, interested.

MIDDLE WEST

Fire, June 14, destroyed the plant of the Goodrich Rubber Co., Akron, Ohio, manufacturer of rubber good. Loss, $5,500.

The Acme Woolen Mills Co., 1294 7th St., Cleveland, Ohio, will build a silk mill on West 70th St., Cleveland.

The Lederer Furniture Co., Rose Bldg., Cleveland, Ohio, has awarded the contract for the construction of a new 4-story building at Euclid Ave. and East 61st St., Cleveland. Estimated cost, $150,000. Noted June 15.

The R. I. Dollings Co., Hamilton, Ohio, plans to erect a paving brick plant at Brazil, Ind. Estimated cost, $500,000.

The Ohio Central Glass Co., Lancaster, Ohio, is improving its plant.

A plant for the manufacture of axe and hammer handles will be established by C. W. Nicholson, Latham, Ohio.

The portion of the plant of the Valley Chair Co., Grand Rapids, Mich., recently destroyed by fire with a loss of $150,000, will be rebuilt. Noted June 22.

Plans are being prepared for a large plant for the Piqua Handle and Manufacturing Co., Marquette, Mich.

Fire, June 11, destroyed the plant of the Colson Novelty Co., Paris, Ill., manufacturer of novelties. Loss, $100,000.

The Jewel Belting Co., manufacturer of belting, has had plans prepared for the construction of a factory at 2831 South La Salle St., Chicago, Ill. Estimated cost, $50,000.

The Federal Rubber Manufacturing Co. has awarded the contract for constructing 3 factory buildings at Cudahy, Wis. Noted May 25.

Plans are being prepared by Washington & Kenhans, Arch., Chicago, Ill., for the construction of a packing plant for the Green Bay Stockyards and Packing Co., Green Bay, Wis. Estimated cost, $150,000. F. C. Greiling is interested. Noted June 1.

The International Shoe Co., Wood River, Ill., plans to construct a tannery. Estimated cost, $1,000,000.

WEST OF THE MISSISSIPPI

The Wyman, Partridge & Co., 1st Ave., N., and 4th St., Minneapolis, Minn., plans to construct a factory and cold-storage plant at 5th St. and 2nd Ave., Minneapolis. Estimated cost, $350,000.

The Carey Salt Co. is constructing a 1-story, 160x200-ft. packing plant at Hutchinson, Kan. Estimated cost, $30,000. Noted Apr. 6.

The Solvay Process Co. is constructing an addition to its soda ash plant at Hutchinson, Kan.

J. J. Johnson plans to install a hay press manufacturing plant at Batesville, Ark.

The Independent Gin Co. plans to construct a cotton gin at Lake City, Ark.

The Farmers and Merchants Gin Co. plans to reconstruct its cotton gin at Irene, Tex. George G. White is Pres.

The Fuller Cotton Oil Co. contemplates construction a cotton gin at Snyder, Tex.

The Western Oklahoma Gin Co. plans to construct a cotton gin at Mountain Park, Okla. Estimated cost, $12,00.

The Cottonwood Oil Mill Co., Ringling, Okla., is in the market for equipment.

The Tatums Gin Co. plans to equip a cotton gin at Tatums, Okla.

The Delta Sugar Co. plans to construct a factory at Delta, Colo.

WESTERN STATES

Fire recently destroyed the plant of the Valley Canning Co. at Newberg, Ore. Estimated cost, $15,00.

An addition is being built to the sugar refinery of the California & Hawaiian Sugar Co., Crockett, Calif.

Fire recently destroyed the packing plant of the Sutherland Fruit Co. at Fullerton, Calif. Loss, $10,000.

Bids will soon be received for the construction of a factory for the Wagner Leather Co., 120 Oak St., Stockton, Calif. Estimated cost, $12,000.

The R. W. Pridham Co., manufacturer of paper boxes, 112-124 North Center St., Los Angeles, Calif., has purchased a site on Pacific Blvd., Vernon, Calif., Grafton post office, and plans to construct a plant. Estimated cost, $100,000.

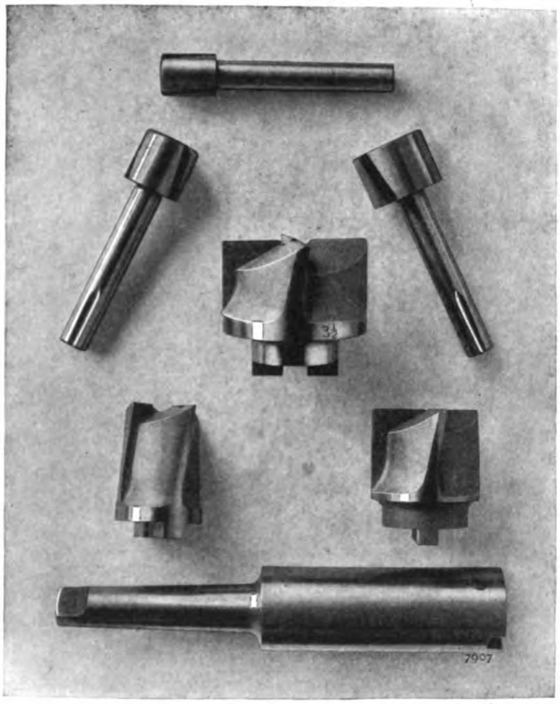
CANADA

The Hamilton Stamp and Stencil Co. has awarded the contract for the construction of a plant at Hamilton, Ont.

Classified Advertising

The Classified Advertising section appears on pages 168 and 169, of this issue and will in future appear in the same relative position in the paper.

The Right Combination At Once



Holder, Cutter and Guide

For every counterboring job you can make immediately the right combination of holder, cutter and guide if your tool room is equipped with

P. & W. Interchangeable Cutter Counterbores

Holders, Cutters and Guides furnished in wide range of sizes.

Holders

End of holder is milled to receive the driving lug of the cutter and there is also a hole and set screw to accommodate the shank of the guides.

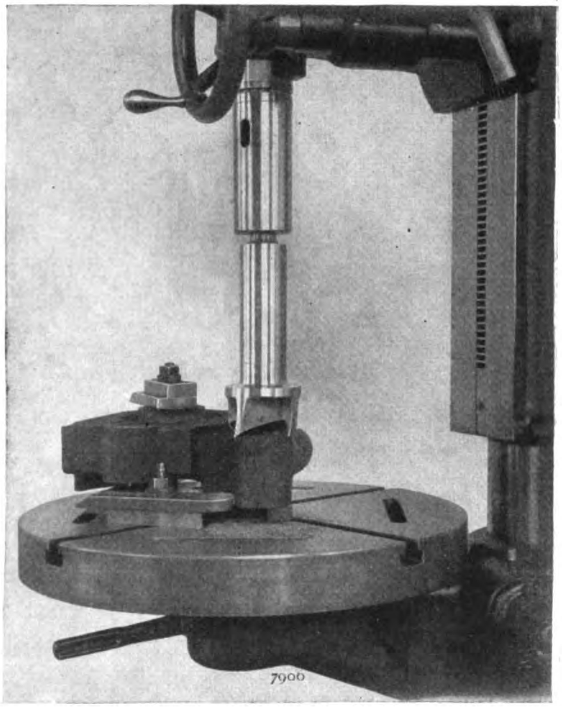
Guides

Are of hardened tool steel. They are held in place by means of a set screw in the holder engaging a V-slot in the shank of the guide.

Cutters

Can be furnished of either carbon or high-speed steel.

The shank of the guide passes through the hole in the cutter and the shoulder between the guide and its shank keeps the cutter in place. Cutters can be sharpened on the face and the guide is simply pushed further in the hole after grinding.



Spot Facing
with a P. & W. Interchangeable Cutter Counterbore.

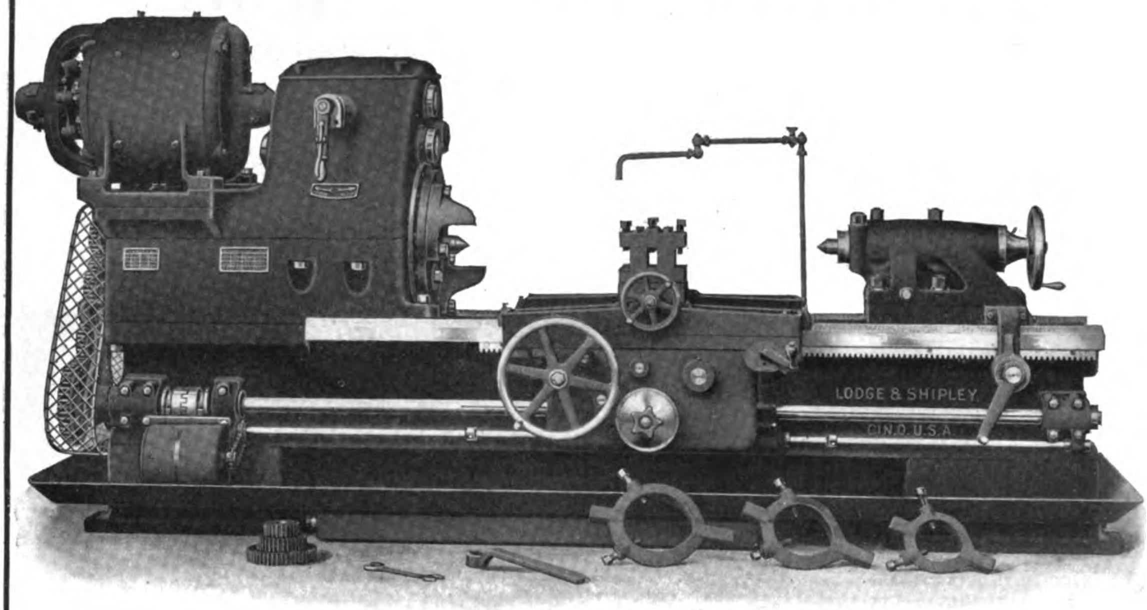
IT'S UP TO YOU
To Take Advantage of These
EARLY DELIVERIES



There will be a few of these HEAVY FORGE LATHES left after we finish some large contracts. These will soon be ready for delivery.

They swing 15 in. over the carriage. Speeds and feeds are designed for work up to that size. Full swing is 30½ in. The drive is direct from a 3 to 1 motor.

This machine is especially built for cutting large quantities of metal in a short time.

BUILT TO STAND UP UNDER THE HEAVIEST SERVICE

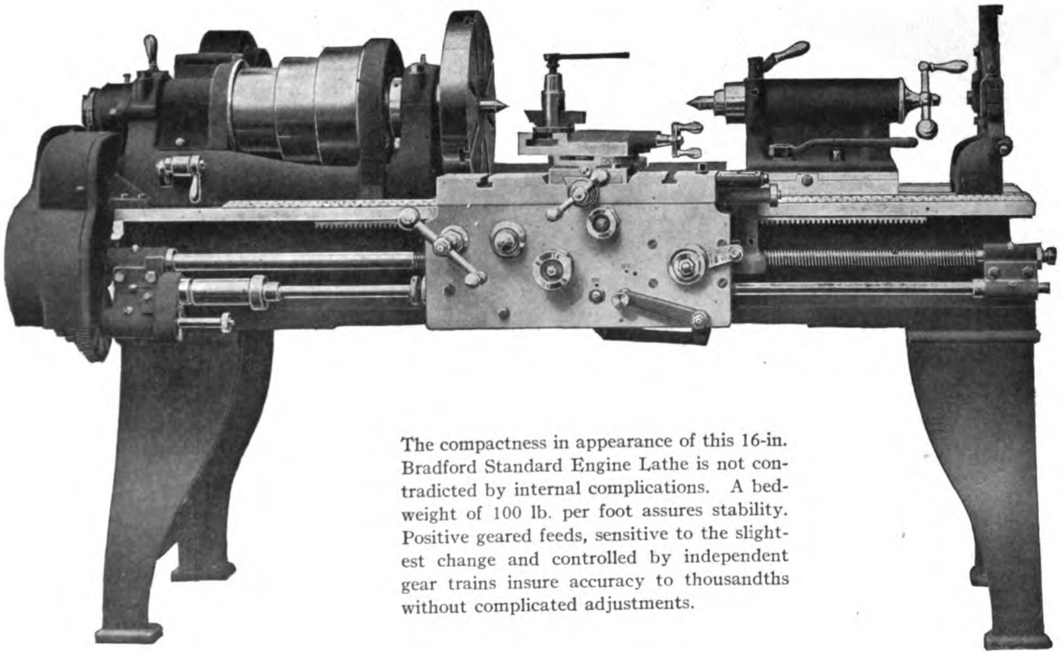
The Lodge & Shipley Machine Tool Company
Cincinnati, Ohio

A Bradford Talk

To the "General Purpose" and "Small Shop" Engineer



The compactness in appearance of this 16-in. Bradford Standard Engine Lathe is not contradicted by internal complications. A bed-weight of 100 lb. per foot assures stability. Positive geared feeds, sensitive to the slightest change and controlled by independent gear trains insure accuracy to thousandths without complicated adjustments.

You don't need a "one purpose" machine—yet. On the other hand the nature of your work demands that every tool and machine you have must "earn its keep." To do this you need the all-round machine of which this Bradford Lathe is perhaps the finest example.

From 16-in. to 42-in., Bradford Lathes will take care of the heaviest jobs or the finest and closest micrometer work.

We believe that a little mutual discussion would be profitable to us both. Why not tell us your problems and let us suggest the remedy?

The Bradford Machine Tool Company

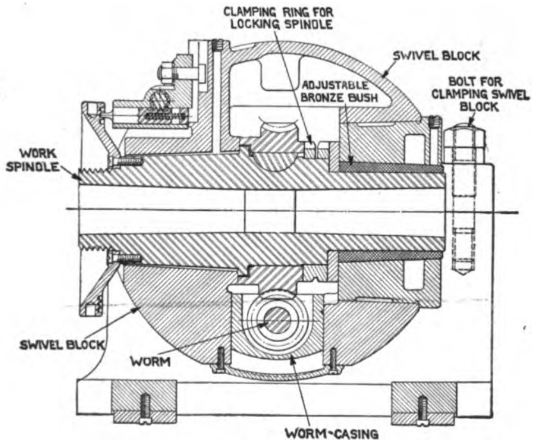

FIG. 4

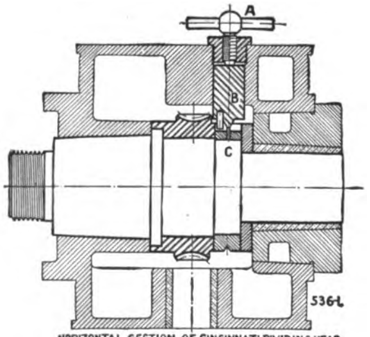
members which grip the entire circumference of the trunnions. This insures rigidity, and also protects the bearings from injury, thus preserving the alignment of these parts.

These are some of the essential factors that contribute to continued accuracy.



HORIZONTAL SECTION OF CINCINNATI DIVIDING HEAD.

FIG. 5.

The spindle clamp consists of a split ring, C, that is spread by the wedge B by tightening the screw A, thus clamping the spindle endwise, securely, without crowding it out of alignment.

Summing Up—

When you buy Cincinnati Universal Millers, you get Dividing Head[s] like this:

First of all, each size is big enough to stand up to the service required from the machine. We don't limit a ten-horsepower Universal Machine by putting on it a five-horsepower Dividing Head.

By making them big, they have a chance to retain their original accuracy.

And, we do make them accurate.

You'll find all of this more fully described in pages 67 to 70 in our catalog. Shall we send you a copy?

Another Ingersoll Job for An

INGERSOLL MILLER

8 Hours Milling against 24 Hours Planing

Two Ingersoll Fixed Rail Housings are shown here. They are being milled on one of the 10 Ingersoll Millers in our Shop. This one is a 72-inch by 20-foot, 60-hp. machine.

The time required is 8 hours for each casting against 24 hours planer time. The milling includes top, bottom, bearings, faces of crossrail and housings, bevel on crossrail and housings, all at one setting of castings.

Get Bulletin No. 36—"Suggestive Installations."

Better still, send us your prints and get our suggestions on your work. It will not obligate you in any way.

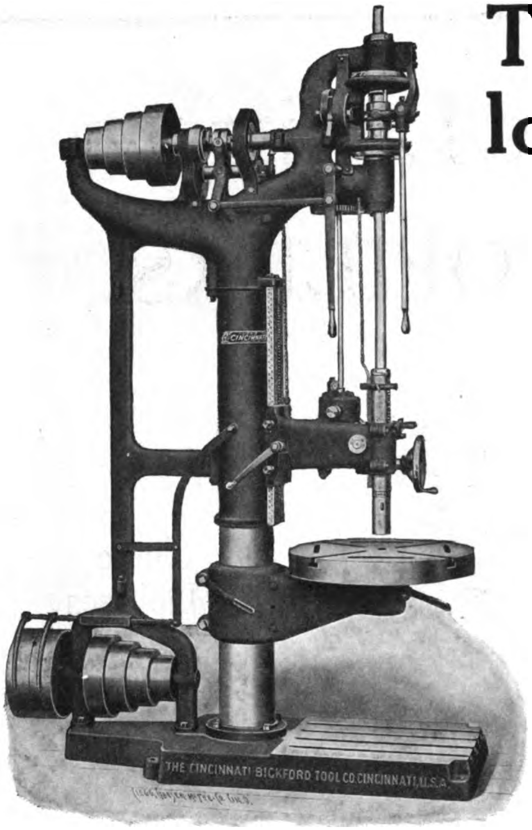
To the man who is looking for facts



THE CINCINNATI

24 to 42-in.
Heavy Pattern
Upright Drilling
Machines

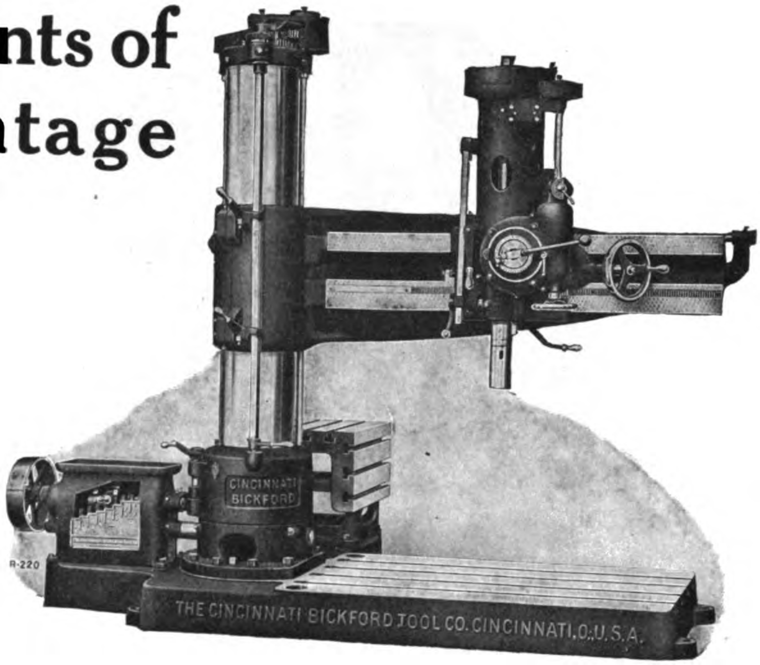
THE drive is furnished in four styles each of which gives, with the back gears, eight carefully selected changes of speed. The Regular Cone Drive necessitates setting the machine parallel with the line shafting while the Right Angle Drive provides for the opposite position. The Belted and Geared Motor Drives permit the drill to be placed at any desired angle. The motors used in these drives are constant speed and therefore require no controllers.

The Tapping Attachment acts through friction clutches and is hence operative at all speeds without shock or noise. It possesses unusual gripping power, is adjustable for wear, and may be disengaged when not required for tapping. Besides eliminating the expense and inaccuracy of tapping by hand, the device effects a great saving in breakage of taps, prolongs the life of their cutting edges, and supplies a convenient means for starting and stopping the spindle when changing tools.

The Automatic Trip disengages the feed at any predetermined depth and guards against the spindle being advanced beyond its intended range of movement.

The Cincinnati Bickford
Oakley,

Specific points of real advantage



CINCINNATI BICKFORD

4, 5 and 6-Foot Regular Plain Radial Drilling Machines

THE head is of unusual construction completely enclosing its gearing, affording protection to the operator and eliminating dust and grit from its working parts, is narrow gibbed on arm and freely adjusted.

The unusually powerful clamping device on column for locking arm in position is very effective and does not change position of arm or drill spindle when operated.

Column fitted with inner trunk having two large ball bearings interposed between them at top which permits the outer one carrying the arm to revolve freely, which allows positioning of drill with extreme ease.

The arm is of most approved design, extremely stiff providing generous support, and long, narrow guideway for head.

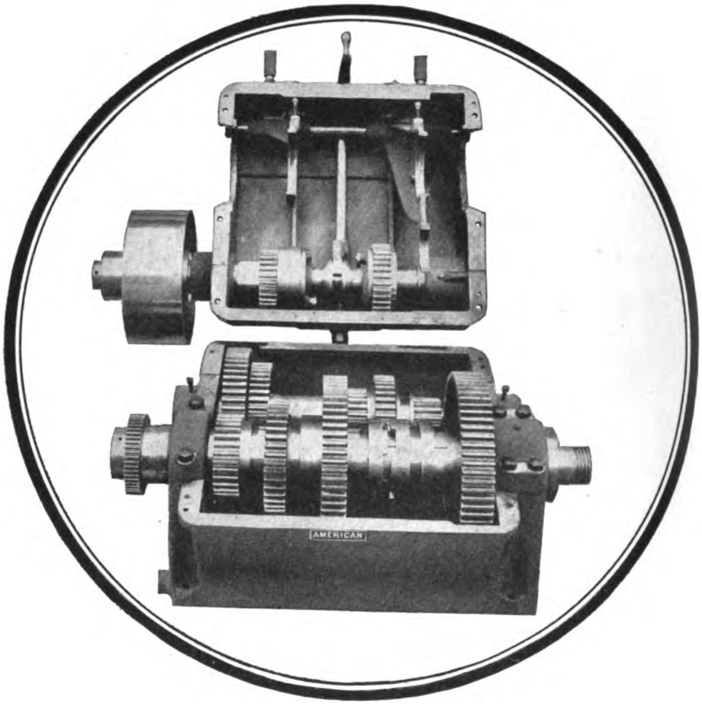
HARTNESS FLAT TURRET LATHE

Stop That Noise

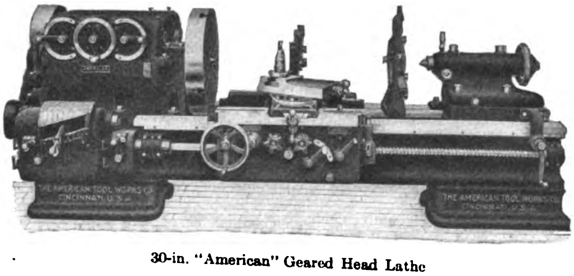
Remember That Your



You can't expect your men to give you the best they have when they are under a constant nervous strain on account of the noise of running gears. The day of quiet-running machinery is here and it is up to you to find and install machines that are noiseless in operation yet high in productive capacity.

Right here is where the "American" Patented Geared Head Lathe fits in.

There is no longer any excuse for a noisy geared head lathe in your shop. The number of running parts in "American" Geared Heads have been reduced to a mini-



30-in. "American" Geared Head Lathe

HERE ARE THE REASONS

The average face and diameter of the gears in "American" Geared Heads are greater than those of any other simila size Geared Heads built.

The material in the gears and shafts is the best we have been able to obtain for the purpose. All the largest gears are semi-steel, while the smaller gears are cut from the bar, some of them being hardened. Shafts are of high carbon

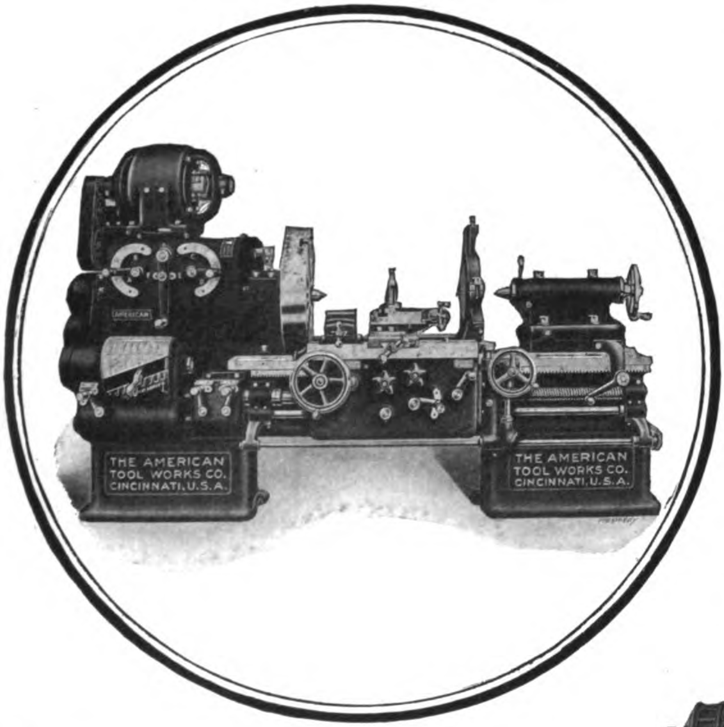
The American Tool Works

Lathes

Planers

In Your Shop

Workmen Have Nerves



mum, the gears are of large diameter, coarse pitch and are cut with special cutters. In addition to this the head is oil-tight permitting the entire head mechanism to run in oil. **This not only insures a quiet drive but greatly prolongs the life of the mechanism.**

As an indication of the stability of the parts—This new type "American" Geared Head has been on the market for over four years, during which time a great many have been sold, and up to the present **we have not had to replace a single gear in any of the heads.**

IN A NUT SHELL:

crucible steel, and all bearings are bushed with phosphor bronze. The highly efficient gravity oiling system supplied is also very important.

Let us tell you where you can see some "American" Lathes operating in your vicinity then you can see all these things for yourself.

At least, let us send you one of our NEW Catalogs.

Shapers **Radials**

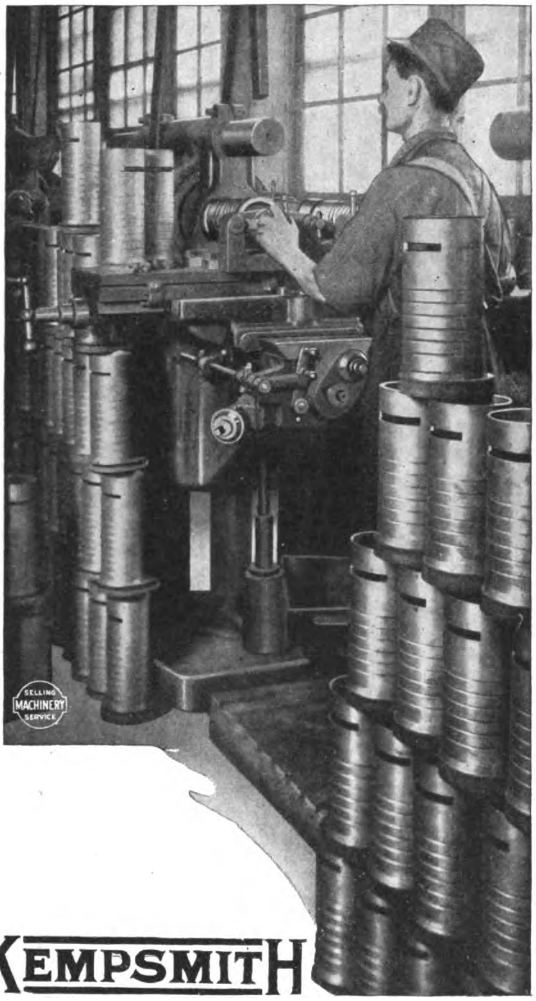
Milling the Sleeves for Willys-Knight Engines

Milling the inlet and exhaust ports in the sliding sleeves for Knight type motors is an economical operation as performed by the Willys-Overland Company (Elyria, Ohio).

The inlet port is $\frac{1}{2}$-in. wide, $3\frac{1}{2}$-in. sector; the exhaust port $\frac{7}{16}$-in. wide, $3\frac{1}{2}$-in. sector.

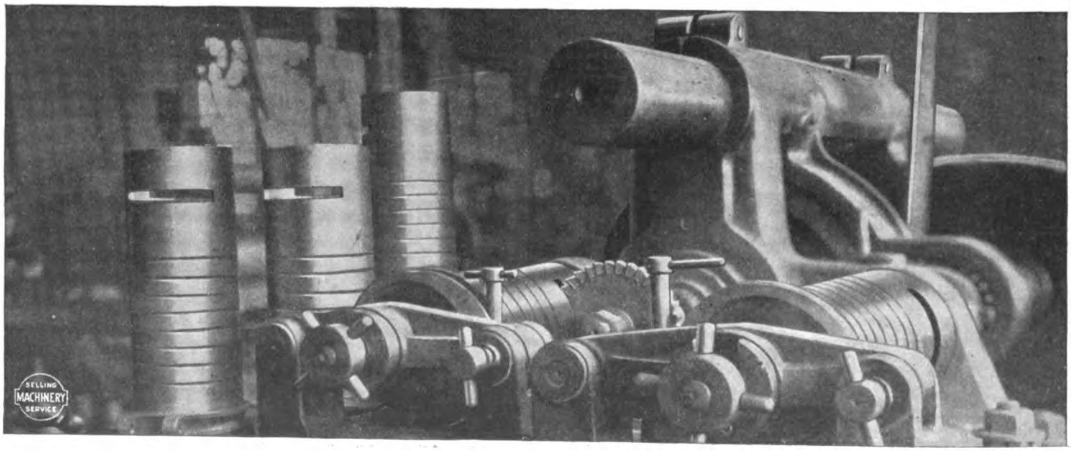
Two fixtures are used on each machine; the operator loads one while the machine is milling the sleeve in the other.

The machines used are No. 2 Kempsmith Plain Millers, and output from each is 250 sleeves per day—which indicates speed and stiffness more than sufficient for all ordinary milling requirements.



May we tell you more about this No. 2 and other Kempsmith Machines?

KEMPSMITH



The Kempsmith Manufacturing Co., Milwaukee, U. S. A.

"Do it Automatically"

Compare this with your own production figures.

There is only one practical method of reducing costs and that is to turn out more pieces per man per day.

Human endeavor along these lines has about reached its limits. The only way to appreciably speed up production is to "Do it Automatically"—the Potter & Johnston way.

P & J Automatics never get tired or lay down on the job. Once it is set up one man can attend to from **two** to **six** machines and every piece will be exactly like its fellows.

This advertisement is written for you Mr. Reader but it will not benefit you unless you act on it.

Suppose you send us on some of your blueprints and production data and let us tell you how much less it will cost to "Do it Automatically."

What About Control?

THE "NEW BRITAIN" possesses several exclusive features of design which render it very easy of operation and minimize the possibilities of accident.

HAND CONTROL LEVERS on each side and within easy reach of the operator enable power feed to be instantly stopped or started.

A HAND FEED CRANK is also provided for testing all feed movements and tool positions. In setting up, testing and adjusting tools it saves breakage.

THE arrangement of these levers is such that it is impossible to start the power feed until hand feed crank is removed, thus preventing any accident which might otherwise arise through operator's forgetfulness.

THE "NEW BRITAIN" is so designed that, in the event of a tool breaking, by withdrawing the tool slide and throwing out the locking pin, the spindle cylinder can be revolved into the most convenient position for sawing off the end of the bar containing the broken tool.

The "New Britain" Six-Spindle Automatic is smashing production records everywhere. We solicit an opportunity to demonstrate how much it might increase yours.

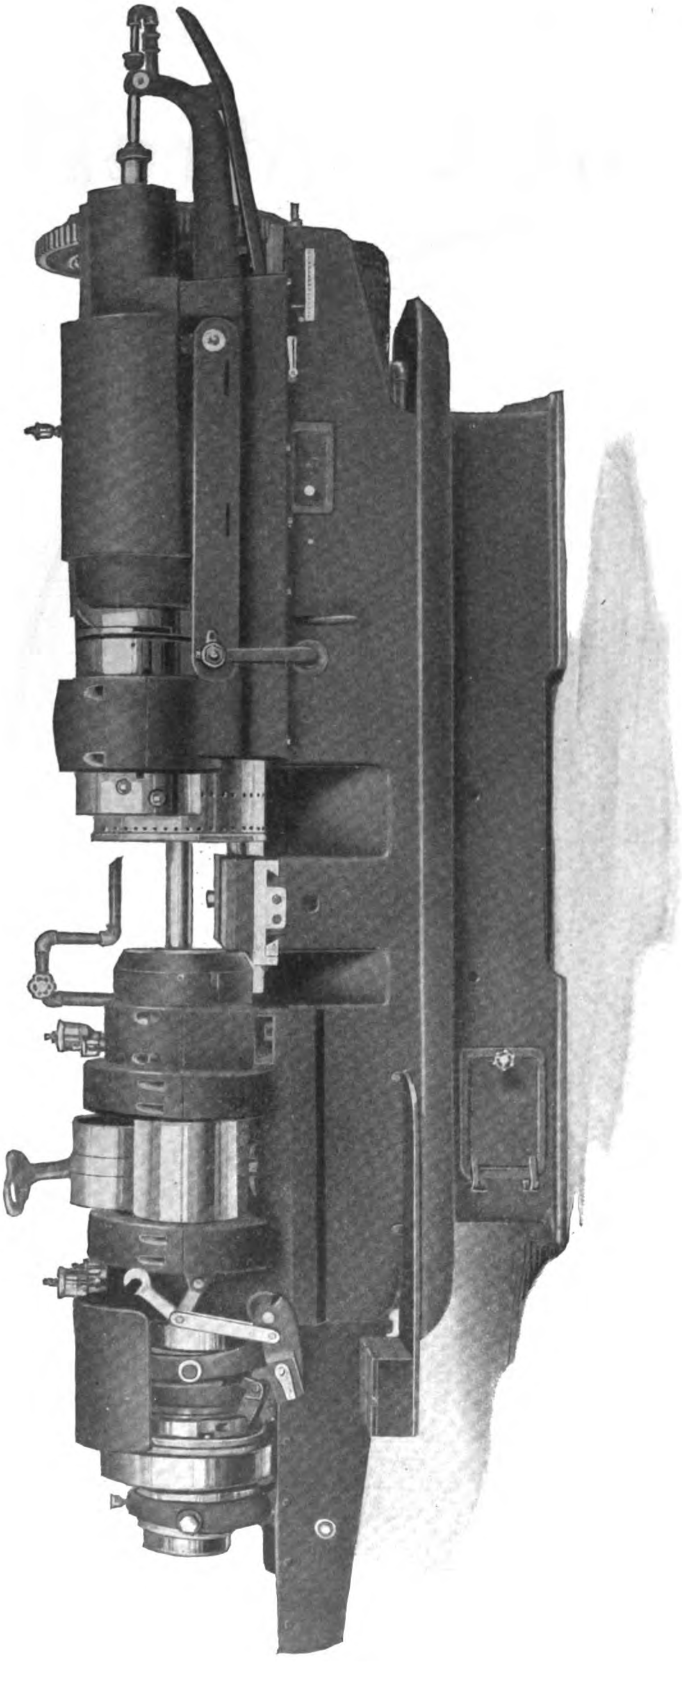
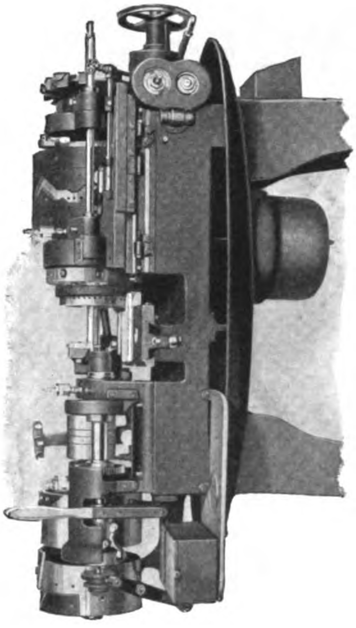
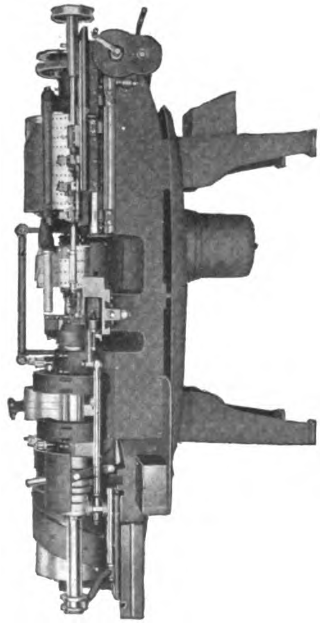
AUTOMATICS







Nothing Flimsy About Our Design

You will remember there is nothing flimsy about our machine, no overhanging, yielding parts constantly annoying when trying to produce duplicate parts. When you encounter such troubles, up goes your cost. No user of a CLEVELAND has this complaint to make.

Solidity and staying qualities are great assets with us. What we guarantee to do is always done.

Cleveland Automatic Machine Company

Cleveland,
Ohio

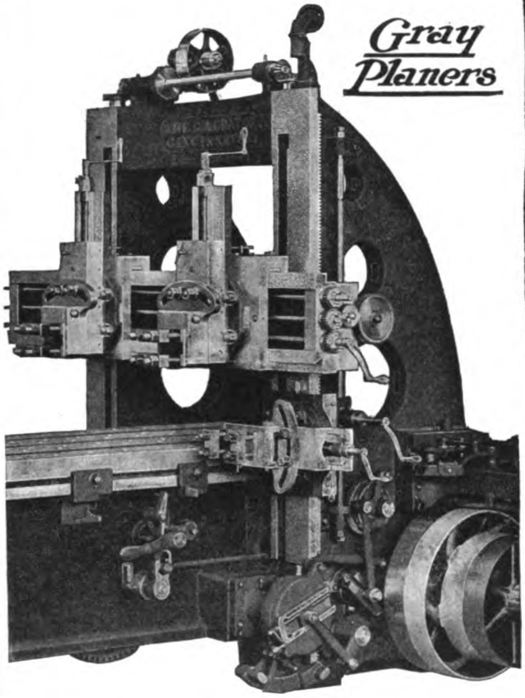
No Torsional Strain

As the driving gears are keyed to the hubs of the pinions the driving power is transmitted through the massive pinion sleeves, thus relieving the shafts of all torsional strain. This insures a smooth movement of the table, increases the life of the cutting tools, and produces better work. We are giving the valuable distinctive features of

GRAY PLANERS

week by week. Write for our illustrated catalog. It tells the whole story.

The G. A. Gray Co.
Cincinnati, O.



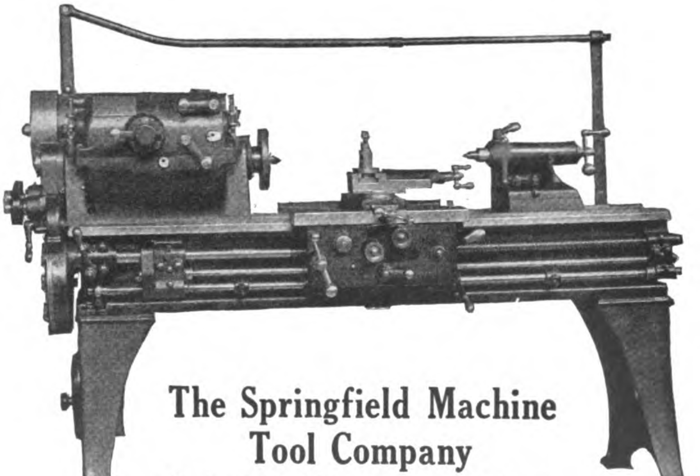
Springfield

Single-Pulley Geared Head Lathe

Investigate the new **Springfield** 14-in. x 6-ft. Single-Pulley Engine Lathe. You will find that correct speeds for all classes of work within the range of the machine are provided within the geared head, and any speed can be instantly obtained. Ball Bearings throughout, with the exception of the main spindle journals, give high transmission efficiency. Simple construction, with every control lever within easy reach, gives speed to all operations. The lathe is started or stopped instantly by means of the clutch pulley and push-rod, and when desired individual motor drive is readily applied, with the motor in any position—on the lathe head or back of the machine, on the ceiling or floor.

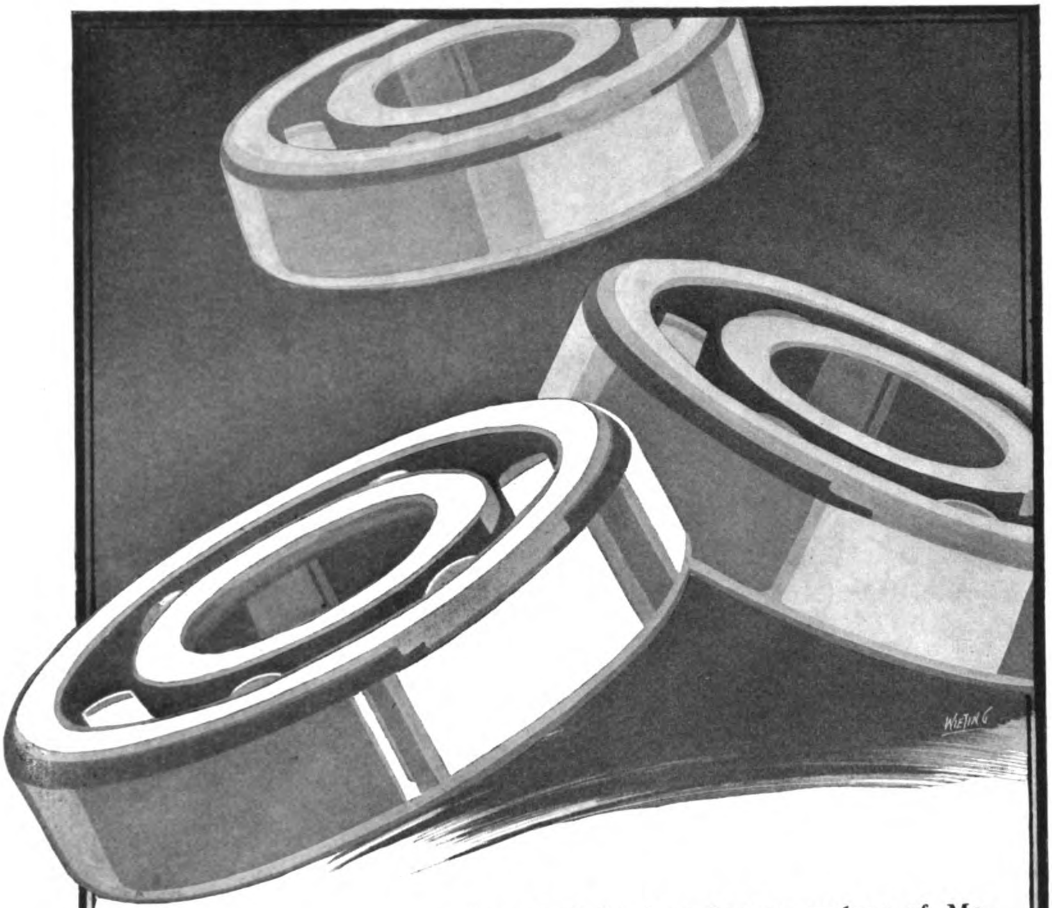
All these are features necessary to successfully meet present-day demands, and in this lathe we have combined them under truly "Ideal" conditions.

Write for complete details.



The Springfield Machine Tool Company
Springfield, Ohio, U. S. A.

HESS-BRIGHT



Several of the best known makers of Machine Tools have used Hess-Bright Ball Bearings for many years—the fact that these manufacturers still prefer this inimitable bearing is concrete evidence of their superiority.

Hess-Bright's Conrad patents are thoroughly adjudicated.

Hess-Bright Mfg. Co.

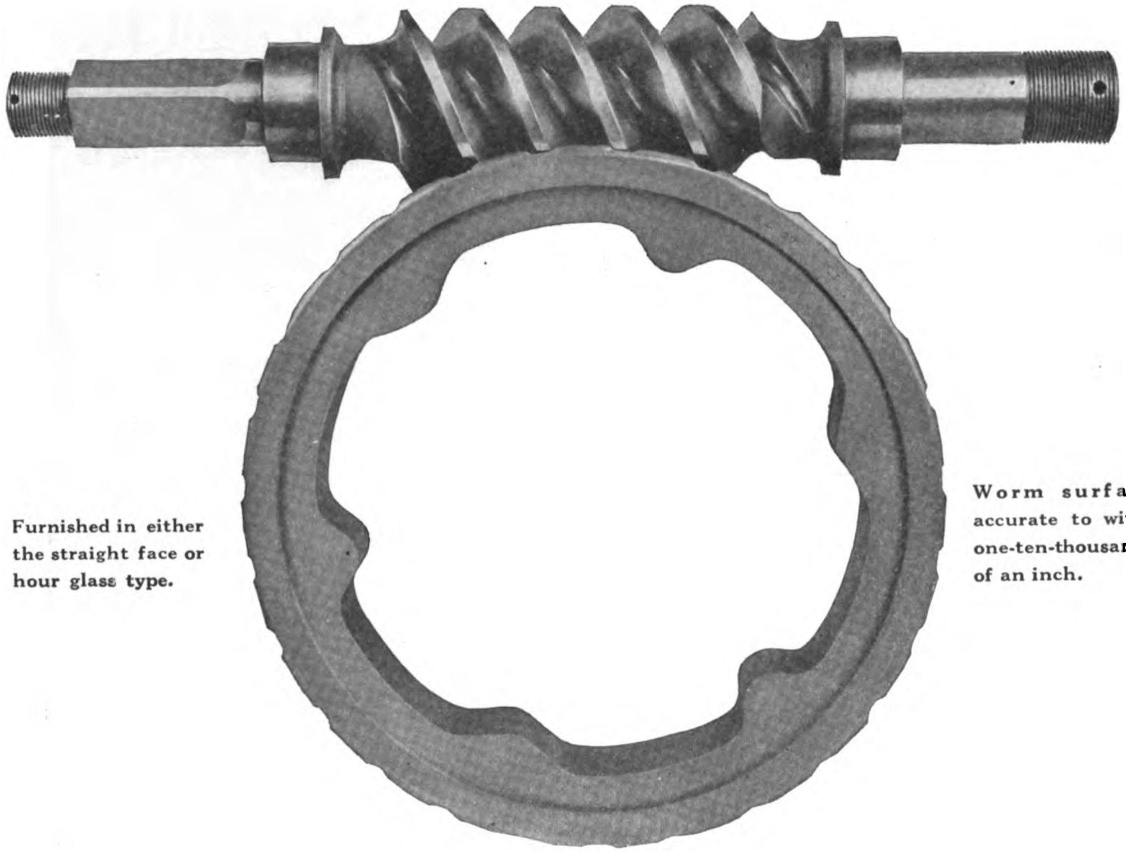
Philadelphia, Pa.

BAUSH

WORM DRIVE

Furnished in either the straight face or hour glass type.



Worm surfaces accurate to within one-ten-thousandth of an inch.

From 1% in 1913 to more than 50% in 1916

These figures show graphically the acceptance of the worm gear type of final drive by the truck users of this country. Abroad worm gear was the dominant type of drive even before 1913 and today is accepted as practically the standard type of drive.

Since 1913, when worm drives were given their first serious consideration in this country, this type of drive has steadily grown in popularity until more than half of all the trucks produced for 1916 will use worm gear driven rear axles.

This dominancy of worm gears is due solely to the greater efficiency of the worm gear type of drive judged from any standpoint. The average life of a worm gear is exceedingly high—it improves with use—it is extremely quiet in operation and requires little or no attention during its entire life.

HEALD MAGNETIC CHUCK

at

Mailometer Shop

"We are very well satisfied"—

—says the manager of the Mailometer Company, referring to the chuck. Results at shops of Dayton Stamping & Tool Co., Page Needle Co., Union Caliper Co., Barber - Colman Co., Crocker-Wheeler Co., National Carbon Co., and scores of others are reasons why *YOU* should investigate HEALD Chucks.

The Mailometer Company, Detroit, uses its Heald Magnetic Chuck mostly for grinding die parts and other special tool work. That is why the machine is equipped with the narrow wheel shown in the photo.

When the picture was snapped, however, the Chuck was loaded with washers which are occasionally handled, though of course a larger wheel would be used, were it a regular operation.

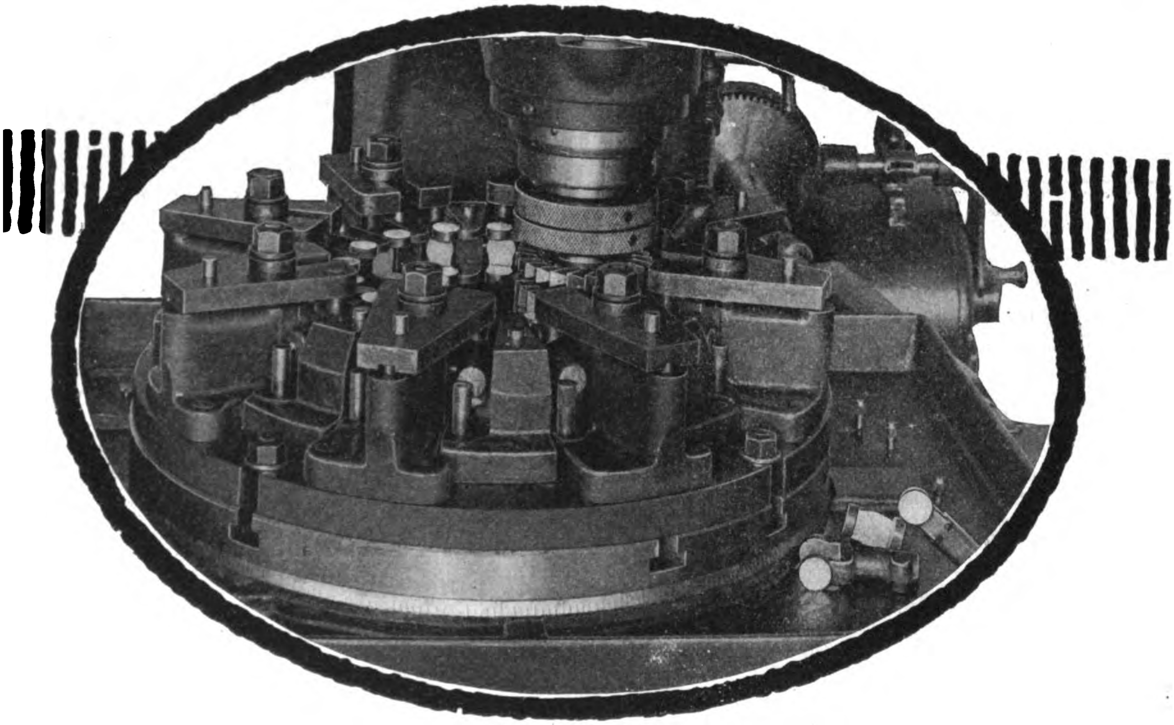
BECKER
Continuous Milling



Becker increased production over 900%

The Steering Reach Rod End (hard drop forging) illustrated opposite required machining on five faces. Production was at the rate of 25 per hour.

Then Becker Continuous Milling took a hand and multiplied that production by five, practically finishing all five surfaces in one operation with an output of 120 per hour.

Is it not reasonable to suppose that Continuous Milling might affect your output, your profits, in the same positive way? Hadn't you better inform yourself about Continuous Milling and its possibilities? Hadn't you better ask us for the Becker Continuous Milling Book?

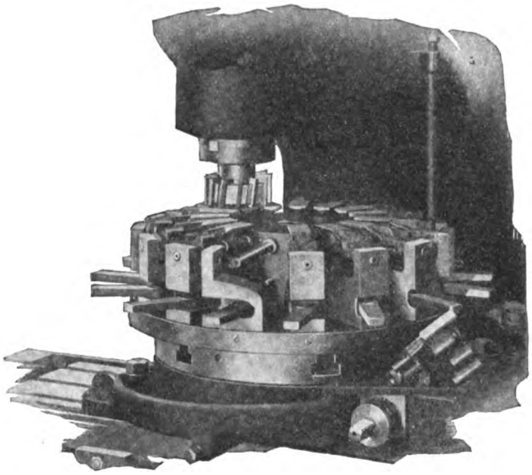
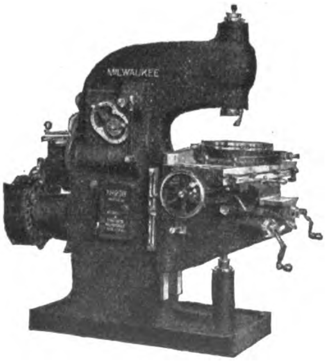
MILWAUKEE MILLING MACHINES





Continuous Milling

The illustration shows the continuous milling of cast-iron pump barrels, a Milwaukee No. 1½B Vertical Miller being employed. The surfaces to be milled are very thin and roughing and finishing cuts are taken within an accuracy limit of .0005 in. The pieces are located in the fixture by two previously bored holes and owing to this method the loading and unloading is not as rapid as would be the case where pieces are simply placed in the fixture and clamped. 750 pieces are finished in a day, which is a meritorious performance considering the character of the work and the method of chucking.

Manufacturing milling by the continuous process as illustrated is an advanced step in milling machine practice and is worthy of the serious attention of the management of any machine shop. The cutter is always in the cut and no time is lost in unloading and loading the fixture.

Milwaukee Vertical Millers are particularly well adapted to continuous milling. The spindle is adjustable for wear only as sufficient and accurate adjustment can be obtained by the adjustment of the knee alone just as it is in the horizontal type of millers.

Milwaukee Vertical Millers embody all the general features that have proven so advantageous in Milwaukee Horizontal Millers. The automatic flooded lubrication system is extended to bearings and gears in the spindle head, not one drop of oil overflowing the end of the spindle. The reverse is self-contained which is a valuable asset in continuous and ordinary milling.

Send for Catalog No. 19, illustrating and describing Milwaukee Vertical and Horizontal Millers.

KEARNEY & TRECKER COMPANY
MILWAUKEE, WISCONSIN

The Story of an Increased Production

WITH a certain make of wheel they were grinding 2,100 large gray iron castings in a Syracuse plant.

A Carborundum service man studied the grinding conditions and specified a Carborundum wheel of a definite grit and grade.

Now, with the right wheel in the right place, they are grinding 3,900 castings under the same conditions.

The Carborundum Wheel cuts faster, cleaner, shows longer life.

Carborundum Service will help you to better bigger grinding results

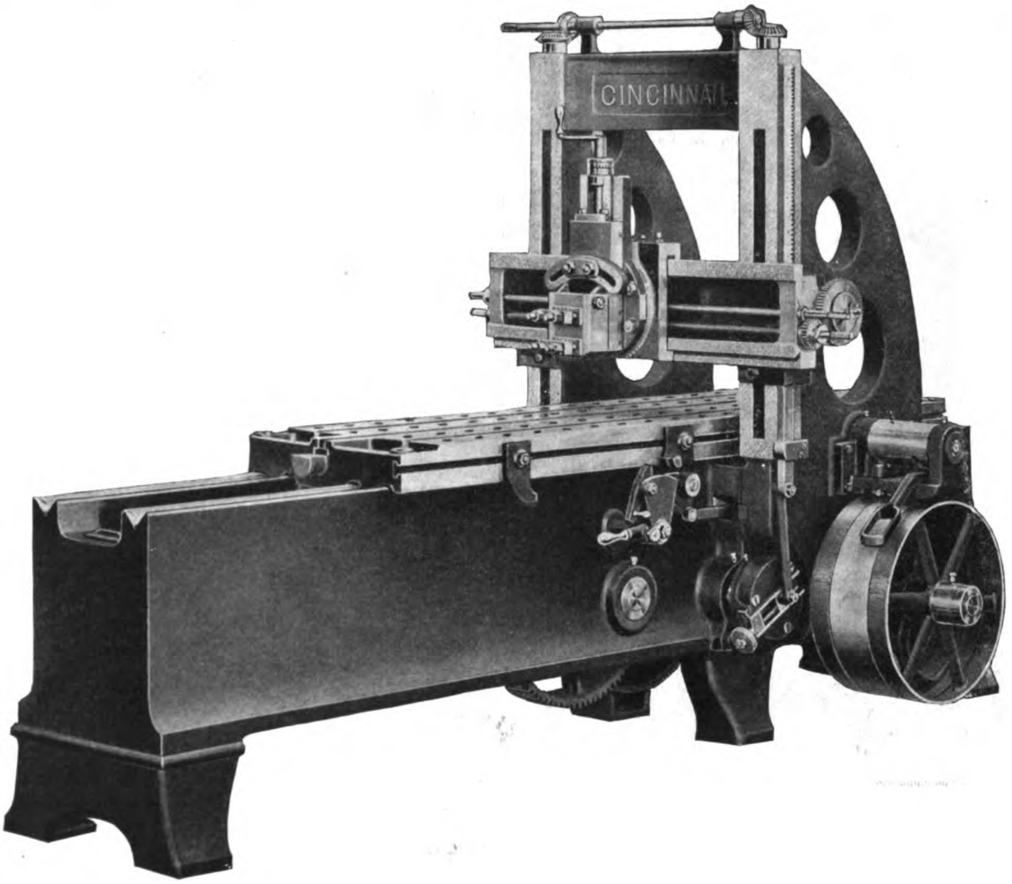
Manchester, Eng. Dusseldorf, Ger.



Features Worth Knowing About the Cincinnati 24-in. Heavy Pattern Planer

Regularly Equipped with the Following:

- Quick reverse aluminum pulleys.
- Extra capacity table.
- Chip guard for V-s.
- Bull wheel revolves with shaft in bearings at side.
- Bed bored to jig for shaft bearings.
- Safety locking device.
- Patent gear-shaped tumbler and dogs.
- Bronze bushed self-oiling loose pulleys.
- Down feed screw and collar one-piece construction.
- Micrometer collars for horizontal and vertical feeds.
- Simplex feed gears.
- All gearing completely covered.

The two-speed countershaft drive gives two different cutting speeds with constant return.

All the driving gears are mounted inside the bed, and each gear and pinion is supported by two bearings eliminating all overhang.

The housings are extended to the bottom of the bed, and are bolted against the sides by bolts and dowels; further locked to the bed by good heavy keys.

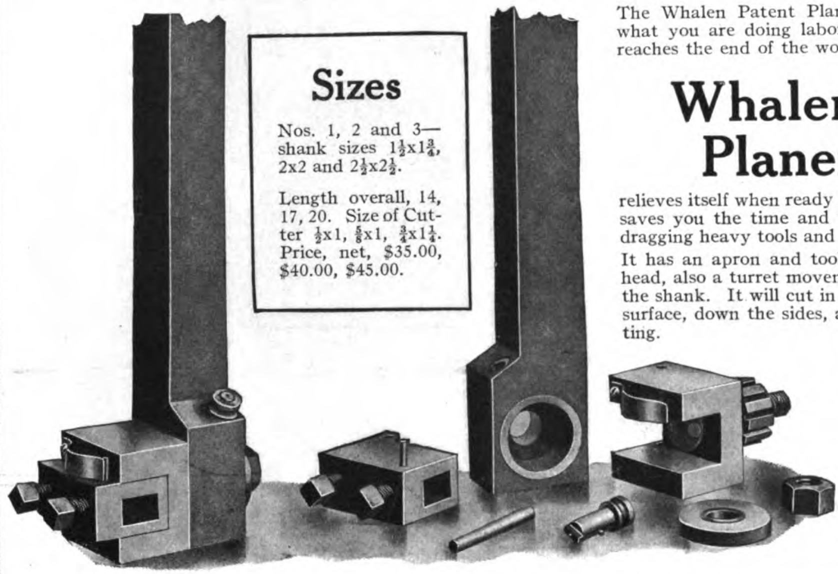
Ends of the bed are made square, instead of S shape rounding. Placing the leg at the extreme end of the bed gives us an exceptionally good support for the table when working its maximum length.

These are only a few of the many features worth knowing about. Get the full story.

The Cincinnati Planer Company

Cincinnati, Ohio, U. S. A.

It Takes Time and Effort to Lift Heavy Tools



Sizes

Nos. 1, 2 and 3—shank sizes $1\frac{1}{2}$x$1\frac{3}{4}$, 2x2 and $2\frac{1}{2}$x$2\frac{1}{2}$.

Length overall, 14, 17, 20. Size of Cutter $\frac{1}{2}$x1, $\frac{5}{8}$x1, $\frac{3}{4}$x$1\frac{1}{4}$. Price, net, $35.00, $40.00, $45.00.

The Whalen Patent Planer Tool does automatically what you are doing laboriously when the planer tool reaches the end of the work.

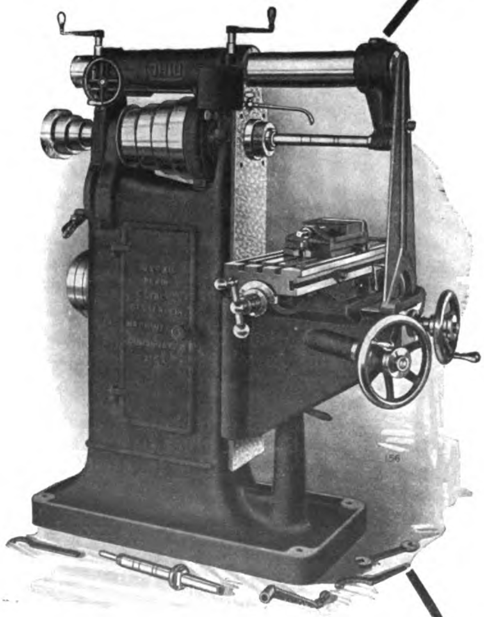
Whalen Patent Planer Tool

relieves itself when ready for the return stroke and thus saves you the time and trouble required in lifting or dragging heavy tools and the clapper block.

It has an apron and tool block the same as a planer head, also a turret movement that works in the end of the shank. It will cut in any position desired, across a surface, down the sides, and do right or left undercutting.

Ask questions and ask for bulletin.

Cincinnati Planer Co.
Cincinnati, Ohio, U. S. A.



THINK

On These Things

They explain briefly why Ohio Milling Machines are so economical in operation. The power, range, convenience and adaptability of these machines have placed them in the front rank for general manufacturing purposes.

The ease of adjustment insures the use of the proper cutting speed.

The cone drive eliminates the loss of power in change-speed gearing.

Oil reservoirs for spindle, back gears and table bearings.

Durability at a maximum—friction at a minimum.

And the initial cost is low. Write for some actual figures.

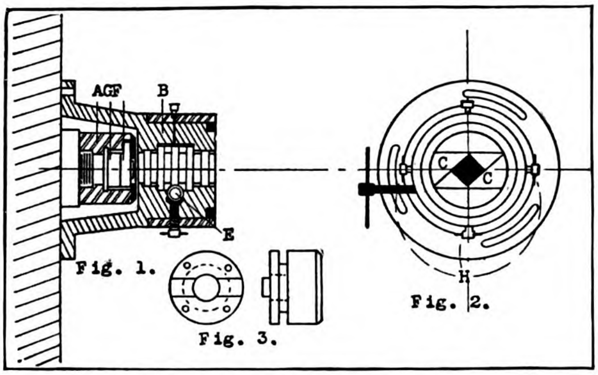
See How Simply and Surely the Radbore Head Drills a Square Hole



Axial Section of Radbore Head

A—Driving member.

B—Stationary guiding member, similar to ordinary drill chuck.

CC—Jaws with interlocking teeth forming master guide in which drill shank turns.

E—Right and left-hand screw for opening and closing jaws.

F—Floating driving dog into which drill is screwed.

G—Loose thrust plate to take up end thrust.

HHH—Locking screws—set upon jaws after running fit has been given the drill.

THE above notation aids in clearly following the operation of the simple principle which makes the success of the Radbore Head.

Guiding member B bolts directly to column of miller or bearing plate of die sinker.

The drill screws into dog G. Tighten chuck jaws so as just to fit the shank and still allow it to rotate.

Dog G does the driving through B. The drill rotates uniformly but also moves around the square opening in the chuck jaws—in a cycle of this movement the cutting points of drill trace a perfect square or a square with fillets in the corners depending on type of drill used.

Now, note on small drawings below that the drill is always in contact with its guide at four points.

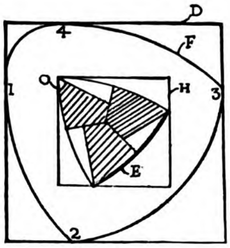


Fig. 4

The Radbore Square Hole is always a commercial hole—accurate, smooth sided and with a flat bottom if desired. Send samples or specifications of your work for further particulars.

Radical Boring Head Corp.

90 West St. - - New York City

Maximum Accuracy—Minimum Cost

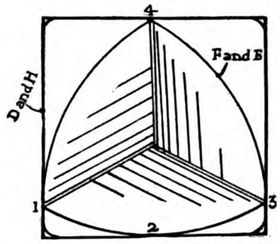

Fig. 5

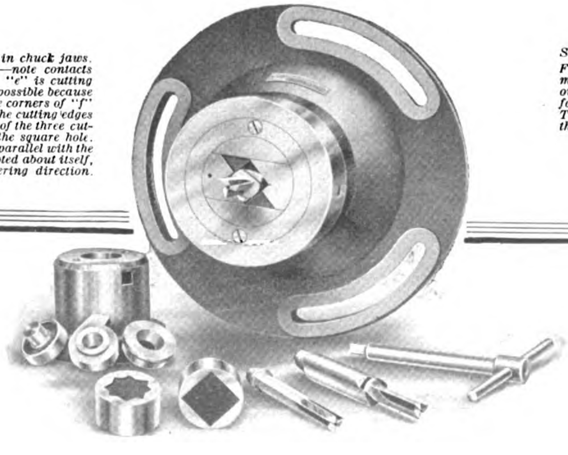
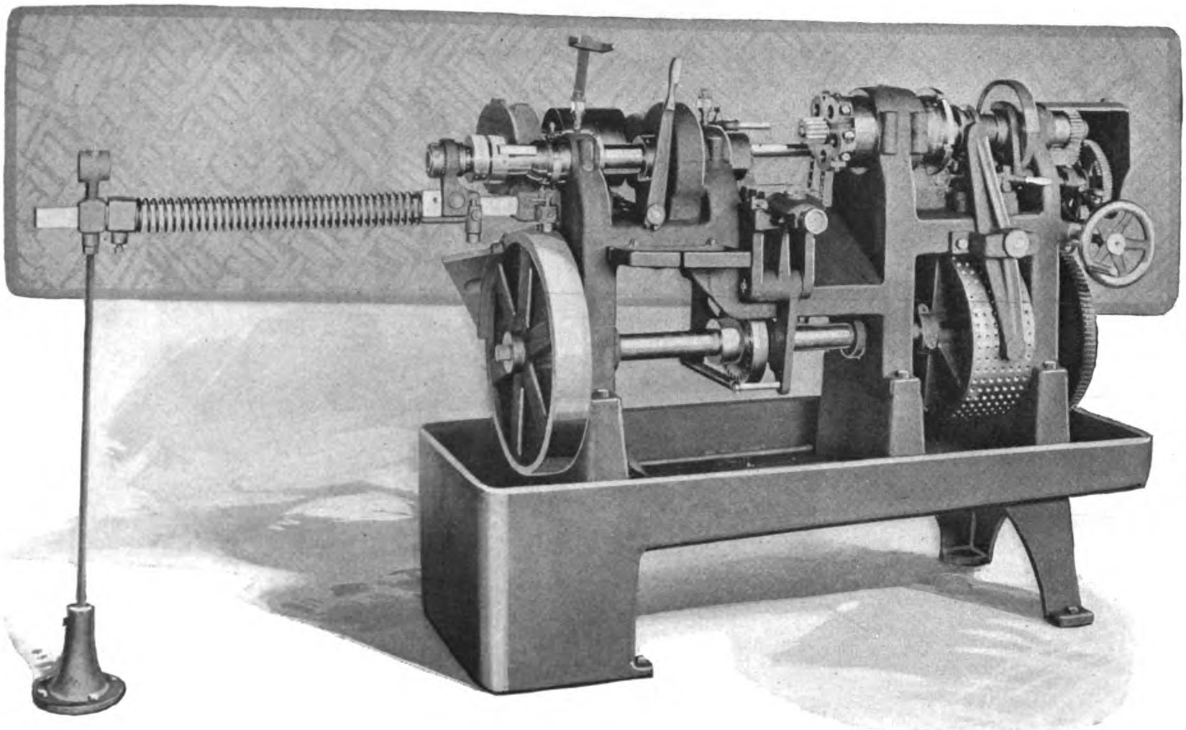
Square holes with sharp corners—

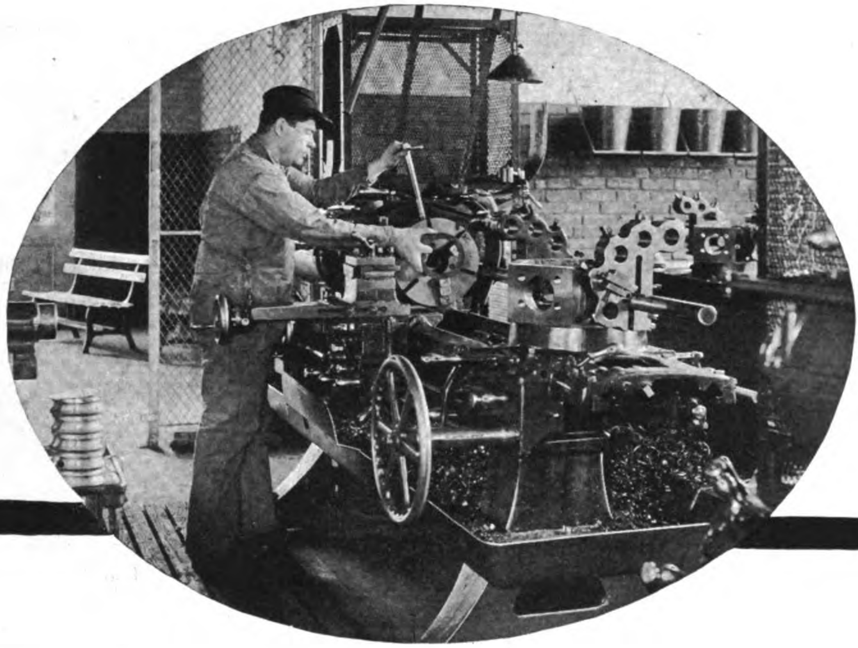
Line "d" represents square opening in chuck jaws. Line "f" is outline of shank of drill—note contacts 1, 2, 3 and 4. "h" is hole being cut. "e" is cutting blade. The perfectly sharp corner is possible because the center of the rounded one of the three corners of "f" at "o" is exactly in line with one of the cutting edges of the blade "e." This means that one of the three cutting edges finishes the periphery of the square hole. The cutting edge is led in straight lines parallel with the sides of "d" and at each corner is pivoted about itself, leading out at right angles to its entering direction.

Square holes with rounded corners—

For this work the shank and drill are made in one piece of same size. Note outline of shank in this case and also four points of contact 1, 2, 3 and 4. These are always present at any stage of the revolution of the drill.







The Speed is there, and Accuracy too

There's power enough to drive the work at the highest speed the cutters will stand, and ten feeds each for the carriage and turret saddle, operating simultaneously, but independent of each other. That means speedy production on the

Universal Hollow-Hexagon Turret Lathes

And there's accuracy. Head and bed are cast in one piece, assuring great rigidity. Turret tools are bolted from inside the hollow hexagon, leaving the entire outer surface of the turret free to support the larger, heavier, stronger tools; and since they need not reach over a "bridged" carriage, the cutters can be shorter and stiffer, reducing chatter to the minimum.

Write for descriptive literature explaining how these machines take two cuts at one time.

Two Recently Installed LANDIS GRINDERS

and Some of the Work They Handle

This pair of LANDIS Grinding Machines has been installed six months—and you can judge for yourself what they are doing and how well they are doing it by the work they happened to be on when the photographs were snapped.

The machine in the foreground is grinding hubs, 3-16-in. wide by 1.5745 in. diameter, on malleable iron differential parts; the limits being nothing over and only 0.0005 in. under size. The second machine is grinding differential gear crosses, four ground sections, $\frac{5}{8}$ in. diameter by $1\frac{5}{8}$ in. long, within limits of 0.001 in.

This work is produced in big quantities, by one of the foremost manufacturers of automobile parts of this character, and you can rest assured that the LANDIS is thought to be the most economical Grinding Machine for the purpose or these two never would have been installed.

Let us send the Bulletin and more details on this new LANDIS Self-Contained Grinding Machine—the grinder in which all overhead works are done away with, in which gearless drive, centralized control and many other features contribute to speed and efficiency.

Make that involved job a cinch

Assuming it is die work of a complicated nature—

The table must be so easily adjusted that the work is get-at-able at every angle.

A wide range of table adjustability is shown in

The Various Tables of the

Cincinnati Shaper

They are peculiarly adaptable to the needs of work that is complicated. The tilting Top for Table, the Revolving Table and the Tilting Table, each one solve a particular problem for you.

Especially is this true of the Revolving Table. It permits work to be held at any compound angle, having a motion of 90 deg. in either direction.

Any one of the tables is readily secured to the apron and in themselves are "production raisers" and "cost reducers."

A Cold Scientific Analysis Of Lo-swing Savings

Not a general blanket statement.

Not a sweeping claim which is so broad that it concentrates on nothing.

No! Not either of these, but instead, a cold scientific analysis of Lo-swing savings *on the specific work you are doing.*

Such an analysis, as made by the Lo-swing Efficiency and Production Department, is worth more to you than all the glittering generalities ever collected together.

And why? Because we focus the ability of the Lo-swing Lathe to save money down to your particular proposition.

For some, the Lo-swing Lathe will save more than for others. Our set-up and time guarantee is made from the blueprints or drawings which you send us, the figures being absolutely individual and correct.

Isn't such a report worth getting? Give us the opportunity to get to work over your shaft subjects.

Send in your drawings now, while the desire to do so is fresh in your mind.

HARTNESS
AUTOMATIC
DIE

Die-Cut Threads of Accurate Diameter

The man whose hands show in this picture is measuring the *pitch diameter* of the thread. He is not using a special thread micrometer for this purpose, but just an ordinary every-day machinist's micrometer. All he does when cutting a U. S. standard thread, is to have the blanks .003 to .004 inch oversize, and then adjust the die until the chasers trim the tops of the threads to standard diameter, as measured by his micrometer.

He now knows that the pitch diameter is standard. He knows it because he is using a Hartness Automatic Die, whose chasers are accurately made with this very point in mind.

This is worth looking into.

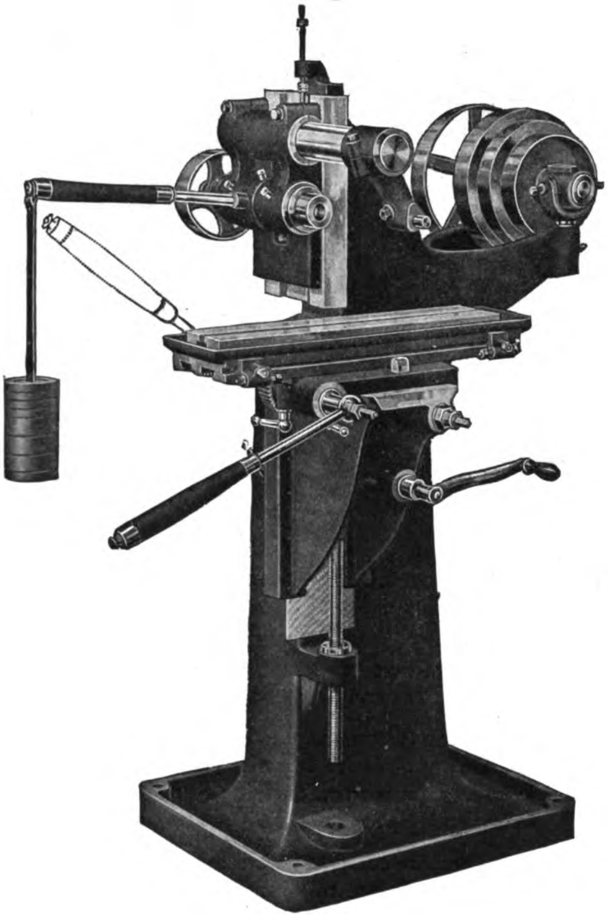
This "Whitney" Hand Milling Machine



is as necessary in your shop as the telephone or type-writer in your office.

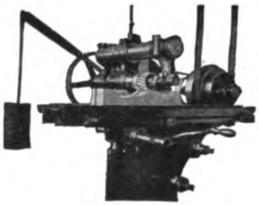
Because it is an all around machine with a wide range of work—capable of taking both light and heavy cuts. It is so well built that it can be used to great advantage in place of larger tools costing twice the money.

It will handle all of your small milling jobs and earn its cost in a short time because there is work constantly turning up that can be done on this machine.

The "Whitney" has features which make it a necessary tool for every shop and tool room. Such as its High-Speed Milling Attachment shown below. This Attachment permits the use of end mills for die sinking, profiling, drilling and all classes of light milling where small cutters and high speeds are necessary.

The Jones & Lamson Machine Co., Springfield, Vt., say: "Your milling machine is one of the most indispensable tools in our milling department on account of its adaptability to many uses."

Keyseating



Profiling

Straddle Milling

Sprocket or Gear Cutting

The "Whitney" can do countless operations in addition to those shown here. Simply fill in the coupon for details.

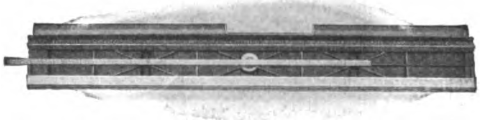
Five Sizes of Plain Grinding Machines. Also Universal, Tool, Cutter and Surface Grinding Machines

Powerful Grinding Machines

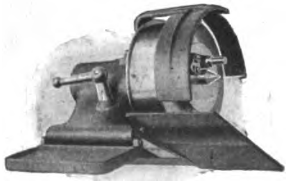
The usefulness of the Plain Grinding Machine is lost if it doesn't have rigidity—unusual rigidity. You may get quality with moderate rigidity, but not quantity.

Now mere weight will absorb vibration, but if not well distributed you have clumsiness and this cuts down quantity again. So every part in Brown & Sharpe Plain Grinding Machines has been studied and given just enough metal to stand up firmly under the heaviest wheel and coarsest feed to be used.

They are compact; note the low-setting type of headstock below. Box form parts like bed and table are thoroughly cross braced; bearings are broad and well backed up with metal. The massive wheel slide in particular, is well supported on walls extending to the floor. And so at every point, they are designed for quantity and quality production.



Under side of table showing closely spaced ribbing



Compact, low-setting headstock

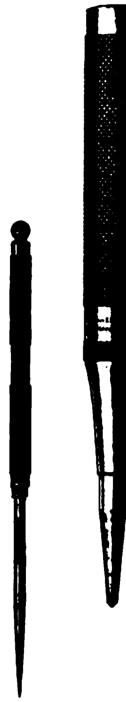
B. & S. Tools That You Need

Did you know that in addition to our big line of mechanics' tools for measuring purposes, which are famous for accuracy, that we also make a number of tools for general shop use that are equally famous for durability and handiness? Here are some examples, all useful tools for men who have to lay out work; look them over.

Such tools get pretty rough use as a rule. That is where B. & S. quality counts. It means the best kinds of steel, drop forged and case hardened parts where the wear comes, clean cut threads and knurling, smoothly finished parts that fit well together. These are the things you want on tools in every day use.



Toolmakers' Vise

Automatic Centre Punch—No hammer required, simply press downward. Punch marks are uniform; point detachable. Several sizes.

Scriber—Finely tempered, detachable point, screws firmly into knurled holder. Made in three styles.

Toolmakers' Vise—Drop forged and case hardened. V-groove in base. Useful when drilling, fitting and laying out work.

Toolmakers' Clamps—Extra rigid; loose jaw held in position by spring; made in half a dozen sizes.

V-Blocks and Clamps—For holding work accurately in position when laying out. Hardened, and ground true in pairs.

Our free 600-page catalog shows many hundred tools for the tool chest of the mechanic or tool room of the shop.

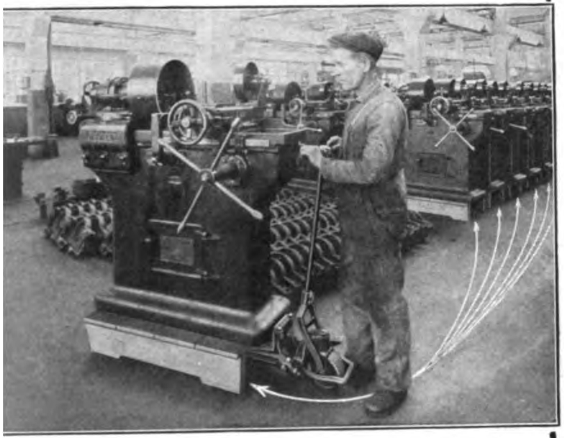
Cowan Transveyors



Make Machinery Mobile

Moving machinery with Cowan Transveyors is no more difficult than moving simple cases of merchandise. The idea is the same. **Look at this picture** and figure the time and labor **you** can save by using Cowan Transveyors.

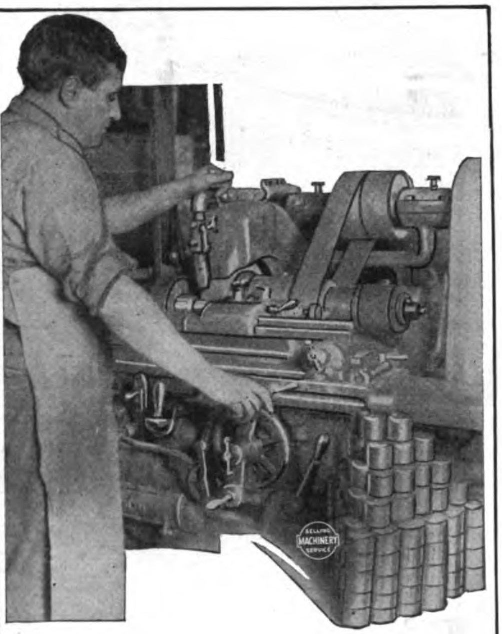
Then, too, they stand up under the load and are eternally on the job.

That's why **The Cowan Truck Company** is known as

Truck Headquarters

16 Water St. Holyoke, Mass.

We have just issued a new catalog showing 24 different uses for Cowan Transveyors. Shall we send you one?



Grinding Steel Rolls for Railway Roller Bearings

Another example of wheel being fed straight into the work is the one shown here—grinding steel rolls for railway roller bearings. The rolls are $1\frac{3}{4}$ in. diameter by $1\frac{1}{4}$ in. long, are carried on centers and driven by a pin that engages a hole in one end. From 0.016 in. to 0.018 in. of hardened steel is removed from each roll and twenty pieces are ground at each truing of the grinding wheel. The table is not traversed, the wheel being fed straight into the work.

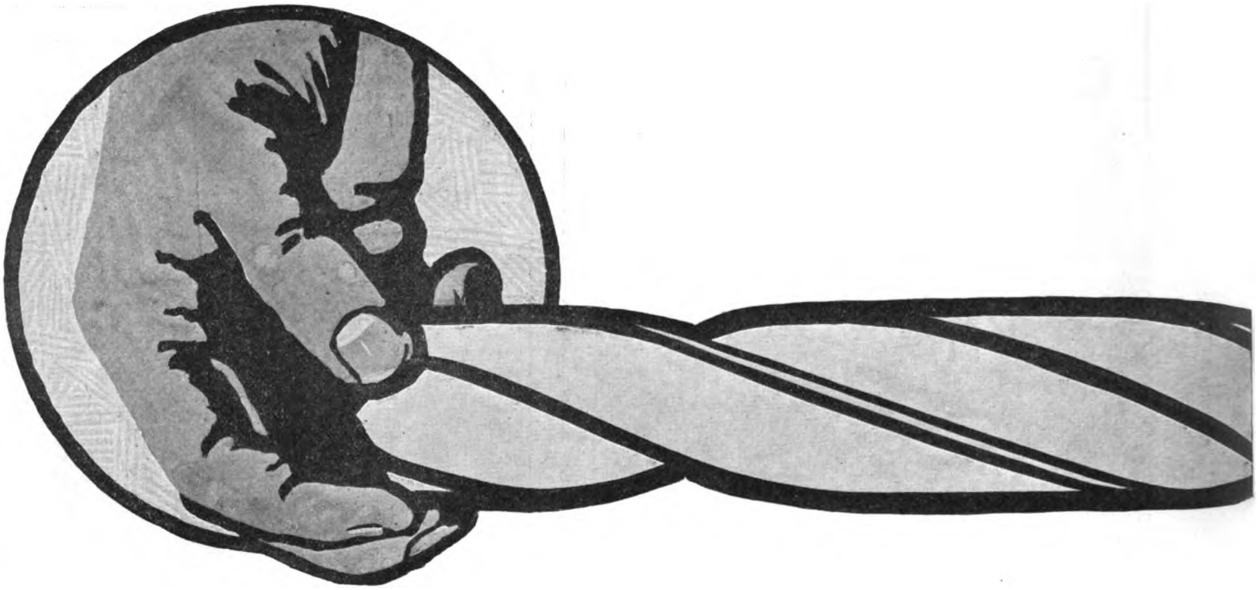
An output of 325 of these rolls in ten hours is average output; when put to the test, as high as forty pieces per hour are ground.

THE WHEEL IS ALUNDUM

Norton Company

Worcester - - Mass.

NEW YORK CHICAGO



Even the "Feel"

Take a Union Twist Drill into your hands. You can almost "sense" its quality—the care and painstaking workmanship which have gone into its making. The weight is so right—the balance so satisfying. And the cutting edge feels so true and keen.

Of course, we do not mean to assume for one minute that the real quality of a drill can be accurately gauged till you have put it to the real test of service.

And that is the test to which we want you to put "Union" Twist Drills. It is in service that their inherent stamina is shown. It is in service that the "feel" of quality is substantiated by the proof of performance.

CAMDEN

Let us make a right-handed job of your rough-turning

We have the equipment to give you Camden Forgings *as you want them*—of your own analysis, turned to specifications.

CAMDEN FORGINGS

are both dependable and available. Our stock list of steel billets and heavy round bars, etc., is complete enough to meet every need—yours included.

We're ready for your inquiries.

Starrett Twin Gas Heater

REG. U.S. PAT. OFF.

THIS HEATER is very efficient in the machine shop, especially in the tool-room, for tempering small tools, melting lead, babbitt, etc., and as a forge for light work. You will also find this heater extremely handy, useful and economical in your home. For laboratory work and wherever a blue-flame burner is required the Starrett Twin Gas Heater has no equal.

Its effectiveness lies in its scientific construction. The gas and air is thoroughly mixed for perfect combustion while passing through the deflectors in base of tubes. The tubes cause the flames to penetrate each other at cross-angles, thus producing an intense heat, free from smoke and with no waste of gas.

CLEVELAND DRILLS

Drill More Holes per Drill

"Don't Scrap This Drill"

Just because its tang is twisted off is no reason for scrapping it. In the tool room you will find a

PERFECT
DOUBLE TANG
SOCKET

Get it. Grind a new tang on the drill—just below the old one—and slip it into the "Perfect Double Tang" socket. You'll have this drill back on the job in three minutes, and it will be 25 to 60 percent stronger than before.

The "Perfect Double Tang" socket gets full drilling life from every drill regardless of the life of the original tang, and it eliminates the waste incident to broken and twisted tangs.

It's in one piece—simple, inexpensive and fool-proof—a necessary adjunct to every economical shop.

"Perfect Double Tang Socket Catalog No. 318" tells about it in detail. Please specify this catalog as you write, since we have others.

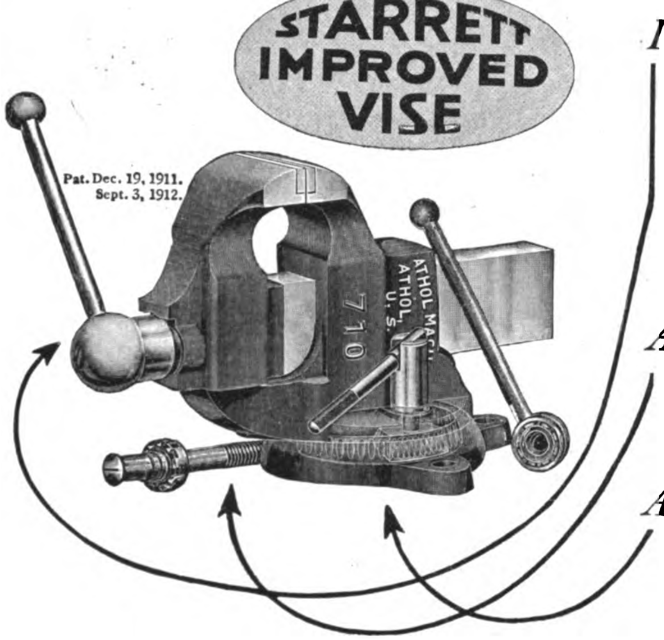
Write for catalog covering our complete line of oxy-acetylene welding and cutting equipment.

The Metals Welding Company
4410 Perkins Ave. Dept. M Cleveland, Ohio



It is improved in this way:

You know that in past vises you have always had two troubles with the handle: First, when the jaws were tight the handle always seemed left where it was most in the way. Second, very often, it had a bad habit of slipping through the screw head and planting a blood blister on your hand. In the Starrett Vise both of those troubles are done away with.

As you can see the handle is screwed solidly to the head and does not pass through. Thus, when you have the jaws tight, you simply pull out the screw head and because of a ratchet arrangement, the handle can be swung to any position you desire.

And in this:

In the Starrett Vise, instead of the old-style, coarse pitch, double square thread, there is used a single pitch thread of the buttress type. The same pressure applied to our thread gives twice the power of any double thread of the same pitch. Accordingly, you can make the jaws tighten more easily.

Also in this:

Note that phantom view of the corrugations of the bolt engaging with the corrugations of the base. After the clamp nut is tightened by hand, the swivel base cannot slip. It is absolutely rigid.

Now these are only some of the ways in which a vise has at last been brought up to date to meet modern needs. Get acquainted with these improvements.

At last here, in this Starrett Vise, is a vise with big improvements—several of them. Doesn't this interest you? Write for the booklet "Something New in Vises."

Fast and Safe Punching Is All a Yankee Power Press Can Do

THE ordinary hand and screw press is rendered obsolete by the little **Yankee Power Press,** which is just the thing for small, light work.

The clutch is so controlled that it cannot make a second revolution until the foot is removed and again applied to the treadle. But if desired the device may be adjusted for continuous motion.

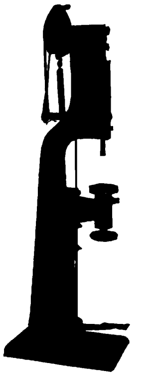
The Yankee is built in three sizes, No. 0, No. 1 and No. 2. It is supplied without table for use on a bench.

We also build cam milling machines, disc and surface grinders and special machinery.

You ought to write for circulars and prices on these products.

The Rowbottom Machine Company

Waterbury, Conn. **Factory, Waterville, Conn.**



Accurate Riveting

with our
"ELASTIC ROTARY"
(Trade Mark)
Blow Riveting Machine.

It strikes a series of light, elastic blows, every one on exactly the right spot, and as the hammer is also revolved rapidly, the rivets are turned down smoothly on all sides, and every head is perfectly finished.

Can we send you catalog 14?

FLATHER AUTOMATIC GEAR CUTTING MACHINES

are accurate, rigid and economical.

E. J. FLATHER MFG. CO. NASHUA, N. H., U. S. A.

You DO Need Us to Make Your Gears—and for Good Reasons.

When you say to yourself "We don't need the New Process Corporation to make our gears—our boys can make 'em just as well," nine chances in ten you have never given the matter real thought.

Your men are probably well trained and reliable. They *may* turn out nice gears—and they may *not*. But how on earth can you expect them to compete in cost with our special tools and operatives that produce *gears only*? And can you expect the same accuracy and uniformity as you get from our staff of gear designers, our precise measuring devices and our rigid inspection system? Hardly.

Production in our plant is on a scientific management basis as to both quantity and quality. Our up-to-date equipment of brains, energy, machines and plant assure good product and attractive price—and the free advice of our engineers helps to make strong satisfaction stronger.

Our very first quotation on your prints or specifications would prove interesting.

YOU CAN'T PUT YOUR GEAR WORK INTO BETTER HANDS

TESTING APPARATUS. Making Sure of Quality

Pyroscope (Temperature Indicator)

There is only one way to make sure of quality in the materials you buy, and in the products you sell—that is to *test* them. The two instruments shown herewith are the simplest and most economical for their respective purposes.

To determine how hard or tough is any metal—what is the resistance to wear or shock—you need the **Shore Scleroscope.**

For control of tempering, annealing or any other heating operation, the **Shore Pyroscope is the practical device.**

Write today for booklets fully describing the uses and benefits of these instruments.

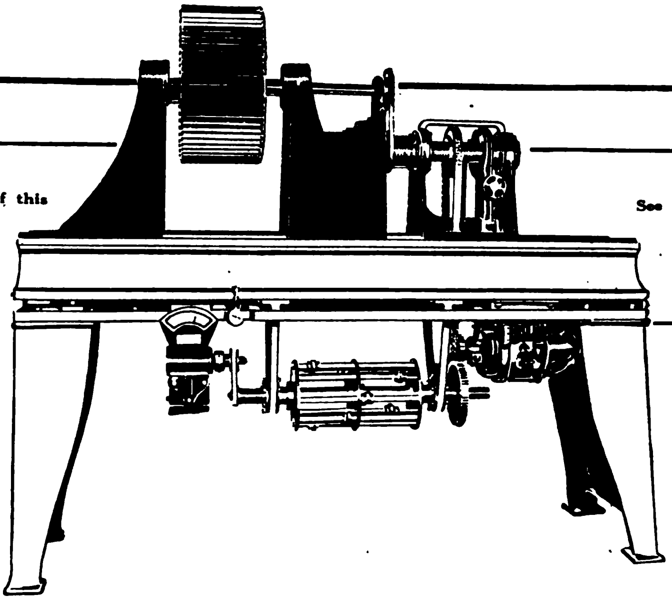
Gaston Marbaix, Factory Agent.



For description of this machine see American Machinist, May 18th.

See also our ads. in these columns under June 8, 15 and 22nd.

THE GREAT RAILROAD for whom we built this machine could not use the blowers as delivered by the manufacturers, supposedly balanced by "older methods." The blowers would not stay on motor shafts, or would shear them right off. The vibrations caused by such "practically" balanced blowers were tremendous. Our machine stopped all this, but consider the unusual part of it: the user has to do his own balancing, because the manufacturer cannot.

Incidentally these fans are being balanced at only 450 r.p.m. while their running speed varies from 800 to 1,300 r.p.m. This clearly shows that it is not always necessary to balance at the operating speed, provided that the balance is REAL, not SUPPOSED.

In balancing small objects it is best to operate at high speeds, so as to bring out the trifling amount of unbalance, which under low speeds may not be noticeable. But large, heavy objects can be balanced at much lower speeds than one may think necessary.

A few words about critical speeds: our advice (so far as balance is concerned) is merely to **forget it.** We are perfectly aware of the brilliant work done by the English and German mathematicians in connection with the delicate subject of critical speeds. But this is a highly theoretical subject, with which we are not concerned in the least in discussing balance.

The absurd part of it is that any ignorant laborer, operating the silly "floating bearing" machine will tell you all about the change of the **high side** at, and due to, what he has been told is the CRITICAL speed. We earnestly caution our readers against so idiotic a notion; **that** is not the critical speed at all; it has nothing critical about it and has something to do with the characteristics of the "floating bearing" machine itself. As soon as the latter is thrown into the scrap pile, where it belongs, this **critical speed** will disappear.

It is high time for practical men to revise their notions as to balance. We are trying to share with the readers of the American Machinist what little we know on the subject: it is all common sense and works out exceedingly well. Watch these columns!

Want a Ratchet for Hard Work?

Here's a heavy duty ratchet—the Billings' Model A.H.H. that is well adapted to the heavier class of work, that can be used for drilling nickel steel rails, etc.

It's double action (reversible), has large bearing surfaces, and can be adjusted to take up wear.

Write for our catalog of Machinists' Tools.

Billings & Spencer Co.
Hartford, Conn.

HOW MANY LEGS HAS A BENCH ?

"Depends upon its length," you say?

Quite true—double the length, twice the number.

But for a given length of bench, the number of legs required depends upon the *kind of leg* used. It will readily be seen, therefore, that the *price per leg* is not the important factor in the cost of bench construction.

The patented stringer feature (permitting wider spacing) and economy in lumber and labor resulting from their use account for the widespread adoption of

"NEW BRITAIN"
PRESSED STEEL
BENCH LEGS

To build 96 ft. of rigid bench, using old-style legs, requires 17 legs (6 ft. apart); with "New Britain" construction but 13 legs (8 ft. apart) are necessary—a saving of 25% in legs.

In addition you get a bench which is wholly self-supported and, being sectional and fastened to floor only, can be quickly moved without injury.

Why not standardize your bench construction? Bulletin No. 1,200 tells how. It means money in your pocket—and better benches too!

Government Storehouses at Balboa, Canal Zone

Make Inventory Easy

DOES your present stockroom equipment enable you to easily and quickly take inventory of materials on hand? It should because the proper storing and handling of your materials is just as important as the care of your office records.

Concerns like The Packard Motor Car Co., Pennsylvania Railway Co., Marshall Field & Co., The Goodyear Tire & Rubber Co., The Borden Co., The Duff Mfg. Co., and hundreds of others, find inventory taking an easy matter, because their stockrooms are equipped with

Berger's Steel Bins and Shelving

This equipment furnishes ample and convenient storage space for all varieties and sizes of supplies, so that inventory can be made accurately and quickly at any time.

Berger's Sectional Steel Bins and Shelving are strongly constructed on the unit principle, so they can be taken down and rearranged at any time to meet changing conditions.

They afford 25% more storage capacity than wood, will hold exceptionally heavy loads, and are practically indestructible. They are a safeguard against fire, and cannot warp, split or rot.

Reasonable in cost, this equipment represents an investment on which there is virtually no depreciation.

Consider what this equipment would mean in your plant. Then write for full particulars and copy of Catalog R. A.

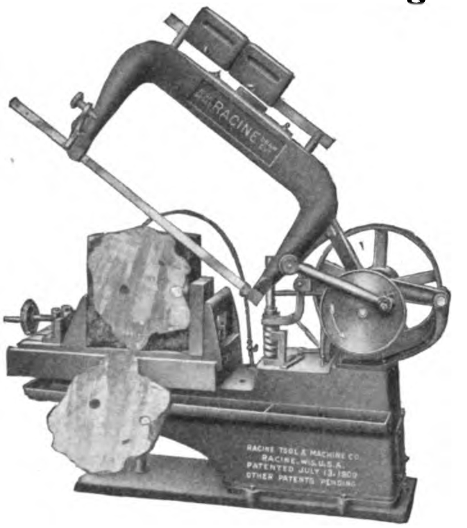
This is the Real Test of Heavy Metal Cutting



A high-speed "Racine" Metal Cutting Machine was selected to cut this Meteorite (which fell near Gibeon, German Southwest Africa) into slices ¼ in. in thickness. Only 1/32-in. variation was allowed yet this 15x15-in. slab of nickel iron was completely and accurately sliced in 10 hours—6 times faster than any other manufacturer could do the same work.

For rapid, accurate and economical metal cutting choose a Racine with its patented device that clears the blade on the non-cutting stroke, tremendously increasing its output and endurance.

We will send you a Racine on any trial basis you consider fair. Make it prove its worth in your own plant before you spend more than postage.

Are You Behind On Cutting Your Steel?

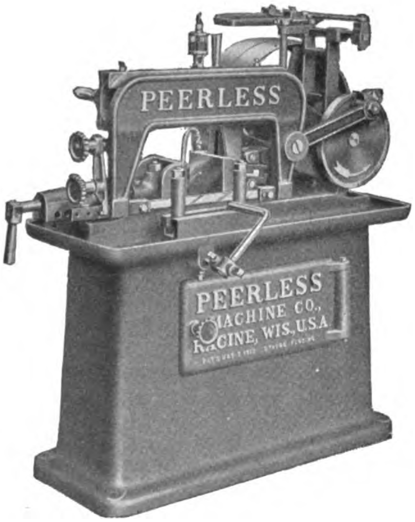
Then read these two paragraphs from a customer's letter. Could anyone expect to hear so favorably from a customer after waiting eight weeks for delivery on machine? It was real production and satisfaction that prompted them to write this letter:

"On arrival of this macnine we were so far behind on cutting that we thought sure one or two more machines would be required for our work, but owing to the high speed and the rapid cutting of this machine it has caught up with our work in a short time. We are now more than pleased that we had the patience and waited delivery on this tool, even if we were put to considerable inconvenience, as a lot of our work had to be sent out to be cut.

We must say that this tool is certainly a great time saver in actual time saved in operating the machine. We figure the operator's time saved alone will soon pay for this tool."

Several other interesting facts in this letter. Would you like a copy together with other descriptive matter?

This machine cuts off 2¼-in. round Manganese bronze in 12 seconds.
Compare this with your cutting time.



Note its rigid construction: it means increase in production.

PEERLESS MACHINE CO., 1615 Racine St., Racine, Wis.

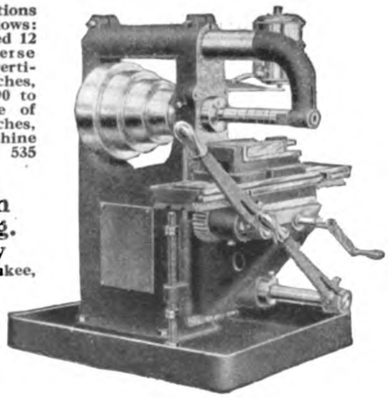
WISCONSIN
BENCH MILLER

For rapid handling and accurate finishing of small duplicate parts you will find this Miller most efficient. Adjustable stops are conveniently placed for limiting vertical and horizontal movements at any position.

Bearing surfaces are scraped true and have suitable means for adjustment. Gears and shafting are all accurately cut and ground to standards. The design and construction, the care and accuracy of manufacture, enable us to guarantee it for a year. Write for catalog.

The specifications briefly are as follows: Longitudinal feed 12 inches, transverse feed 4½ inches, vertical feed 5¾ inches, spindle speeds 90 to 500 r.p.m., size of pan 18x24 inches, height of machine 28½, net weight 535 lb.



Wisconsin Miller Mfg. Company
Station A, Milwaukee, Wis.

The Standard Hand Miller

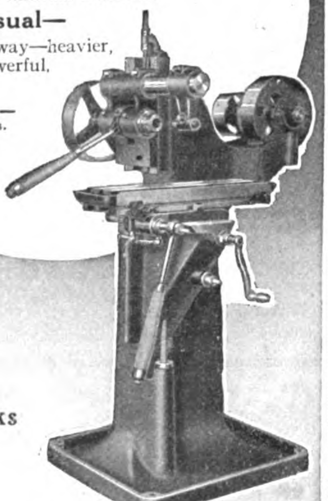
—the machine for accuracy.

That's the big quality embodied in the design and construction of this unusual machine.

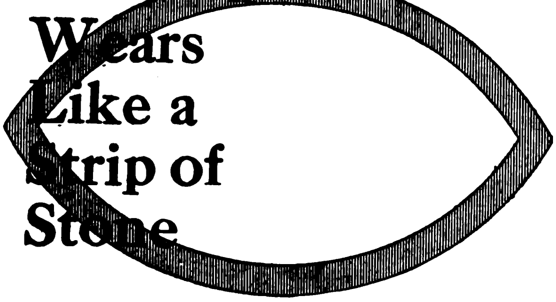
It *is* unusual—

It's bigger in every way—heavier, more rigid, more powerful, and more *accurate*.

Find out why — Get the details. Write today.

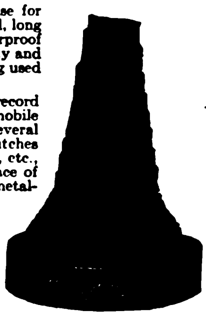


Standard Engineering Works
Pawtucket, R. I.



How about the regular friction facing you now use on your brakes, friction clutches, friction drums, etc.? Does it grip without a slip? And how long will it last?

Raybestos is the logical thing to use for friction facing. It is made of selected, long fibre asbestos, and is heatproof, waterproof and oilproof. It has greater durability and holding power than any friction facing used today.

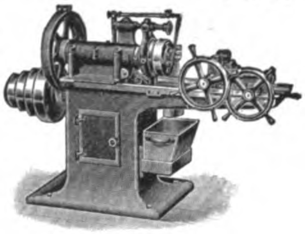


Raybestos has a remarkable 10-year record of satisfactory service in the automobile field. It has also been used for several years in line shaft and machine clutches generally, on hoisting engines, cranes, etc., with the finest results. Use it in place of wood, fibre, cork inserts, leather or metal-to-metal.

Wherever friction surface machinery is used, **Raybestos** is needed. Give us a chance to prove this. Send for the facts.

The Royal Equipment Co.
Bridgeport, Conn.

More Bolt Cutting With Fewer Machines



Many features of modernized design and construction make Acme Bolt cutters equal in work capacity to a greater number of machines of other types.

For instance, the vise is opened and closed by a Hand Wheel. The arrangement of carriage and vise is designed to facilitate rapid feeding of machine so important in handling large quantities of small work profitably.

Write for catalog of details.

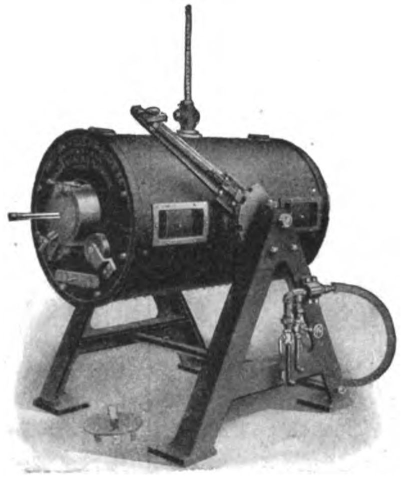
This machine ends all your pipe troubles

Heavy and powerful, it cuts and threads pipe from 4 to 15 inches. Takes less room than any other type. Hand or power operated. Oil pump and U. S. standard dies. Not a Die Stock but a practical machine which enables one man to do four times the work of the old type machines.

The Curtis & Curtis Co.,
66 Garden St., Bridgeport, Conn.

Finish Steel and Iron Work
By
"CARBONIA" Process



No. 64 Heating Machine.

"CARBONIA" or Gun Metal Finish, produced in an AMERICAN HEATING MACHINE, is the ideal finish for steel objects. This process penetrates the metal, but does not change or increase the shape or weight. Being an integral part of the steel, it cannot crack off. A strong resistant to corrosion.

The finish is very attractive to the eye.

"American" Metal Treating outfit (using Gas as Fuel) gives you absolute temperature control. Results are always correct. If you have anything in the coloring, tempering, hardening or annealing of metal products, write us.

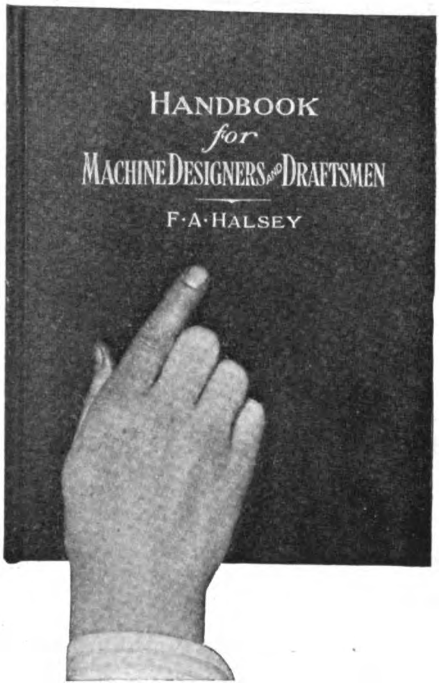
An Essential



FOR every man who has anything to do with the design and construction of machinery Halsey's Handbook is an essential.

This is not merely a broad assertion—it is the testimony of the thousands who use the book.

Mr. Halsey faithfully collected data for 33 years to produce this work. For three years he devoted his time exclusively to its production.

As a result he gives all the data and basic facts used in the design of all kinds of machinery and machine parts—the data which designers, draftsmen, superintendents, engineers and machinists need constantly in their work.

Workers always like Flather Lathes because they are easy to handle and turn out lots of good work without fuss or trouble.

Fifty-four changes are at the instant control of the operator. All adjustments, every working part, are easily accessible.

This wide range of feed and speed makes the Flather Lathe a big favorite in modern shops.

Flather Lathes Boost the Output

Get the complete story of the Flather Lathe. Write to us—today.

Flather & Company, Inc., Nashua, N. H.

Don't Blame the Operator—It's Strictly Up to You

SURE he is running the machine slower than it was intended to run and you are getting less pieces than you should—but that's not his fault. He is trying to keep within the limit of the cooling capacity of the pump. He knows that more speed with that small $\frac{3}{8}$-in. stream would burn up the tool.

IF you really want more production give him a pump and piping that will supply a good HEAVY stream of water compound sufficient to carry away all the heat. Then watch production go up and tool expense go down.

NOW remember this. The "FULFLO" is a small centrifugal pump—a natural pumping principle which assures you a HEAVY flow without too much pressure. The only working part in its pumping action is the impellor. Consequently there are no gears or other close fitting parts to be affected by the grit, dirt or small chips that are always present in the coolant. The "FULFLO" trap arrangement positively prevents loss of its prime without resorting to check valves or any other working part. Since no check valve, relief valve, reverse valve or any other kind of valve is present in the pump or pipe, other than the stop cock, the usual valve troubles are eliminated. All passages are large and open which prevents clogging. As there are no delicate parts to be protected a strainer at the pump is unnecessary. Do you wonder that the "FULFLO" is spoken of as a trouble-proof pump? *Easily attached to any machine.*

WHEN buying that new machine insist that it be equipped with a "FULFLO." You are entitled to the best.

Price of Pump, $10.00

Built just for 3 to 5-in. shell and shrapnel work. Furnished with turret on cross slide, cross slide with tailstock, or plain carriage with turret.

Ask for the details.

The Cleveland Crane & Eng. Co., Wickliffe, Ohio

Earle
Single-Purpose Lathe

Why 24-in. if 18-in. Will Do It?

As a rule, very few shops would care to turn high-carbon steels over 4 in., or at most 5 in., in diameter, on 18-in. lathes. The 24 in. has always been the accepted standard for such sizes.

"Twenty-four inch" cross sections, "twenty-four inch" strength with 18-in. swing—those are the chief characteristics of Earle Single Purpose Lathes. Every part of these lathes is designed to take the thrusts, reactions and twisting movements of average 24-in. machines.

This explains why 8-in. and even 10-in. work in high-carbon steel is being turned successfully and economically on Earle Single Purpose Lathes.

We will gladly send you an interesting anal tical folder on Earle Lathe capabilities, and give you any other information you desire, without the slightest obligation, if you will write.

The Earle Gear & Machine Company

Seattle—536 First Avenue, S.

Aeroplane Characteristics *not* pulley essentials

The resistance of the air against the propeller and planes of an aeroplane raises the heavy machine against gravity.

Bear in mind that the machine *depends* on the beating (displacing) of the air by the propellers.

The energy required for raising an aeroplane is very great.

Still some *belt pulleys* beat the air so hard that one would think they had been built for *fans* or *propellers* rather than *pulleys*.

AMERICAN STEEL SPLIT PULLEY

You can tell these "aeroplane" pulleys quite easily by standing near them. The *breeze* gives them away.

Stand under an AMERICAN—or have you ever tried? You didn't feel any breeze *then*!

Just this one difference between AMERICANS and other belt pulleys accounts for so much of the reduced power waste so noticeable *right after* a shop has been re-equipped with AMERICAN STEEL SPLIT PULLEYS.

The arms of AMERICANS *cut* the air.

Consider this feature in its relation to power consumption when you need pulleys again.

American Pulley Company
Philadelphia, U. S. A.

There's Resiliency but No Stretch

In most "so called" endless belts you will find resiliency and cling—but these virtues are usually offset by the fact that stretching is unavoidable.

Tilton Patented Endless Belts

are not "so called" but really endless—they are woven so—and they are pretreated so that stretching is absolutely eliminated. Yet they have pulley cling that delivers every bit of power transmitted to them.

Send for a sample belt today. Give size.

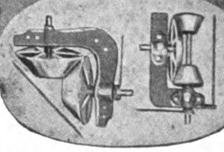
This device affords without doubt the simplest and most effective way of obtaining variable speed. All you have to do to get any desired speed from 1 to 6 is pull the cord. Over 10,000 sets are in use. That's a pretty sure sign of the satisfaction they give.

Let us send you Catalog 25. It explains.

Evans Friction Cone Co., 1288 Centre St., Newton Center, Mass.
A. Warden & Co., 48 Shepherdess Walk, City Road, London, E. C., England.

ROCKWOOD
Paper Frictions



No Breakage From Sudden Shocks

The best engineers are using Friction Transmission. Replacing toothed gears under proper conditions, it satisfactorily meets a wide variety of requirements—unlimited speeds—(forward and reverse) quick starts—sudden stops—highly-efficient and noiseless in operation.

Rockwood Paper Frictions are the acknowledged standard. Made to fit your specifications.

Our booklet, "Friction Transmission," gives data and formulae invaluable to the designer. *Sent free on request* to those who state occupation and firm connected with.

What Was He Worth?

To Himself—To His Family—And to You

After you have trained an intelligent workman so that he is a valuable unit in your organization, why run the chance of crippling him so that he becomes of no value to himself, to his family, or your organization by exposing him to whirling projections on flange couplings and set collars?

Protect your men and your own interests by using

Bull Dog Shaft Couplings

Cathcart U. S. Patents issued and pending

Foreign patents applied for.

These couplings are simple and safe. They have a smooth surface with no projections. Simply a metal cylinder having two eccentric chambers, each containing a rolling lock. The coupling may be slipped on with the hands—no tools required.

Write for full information, prices, and the name of the nearest supply house.

This Ever Happen to You?

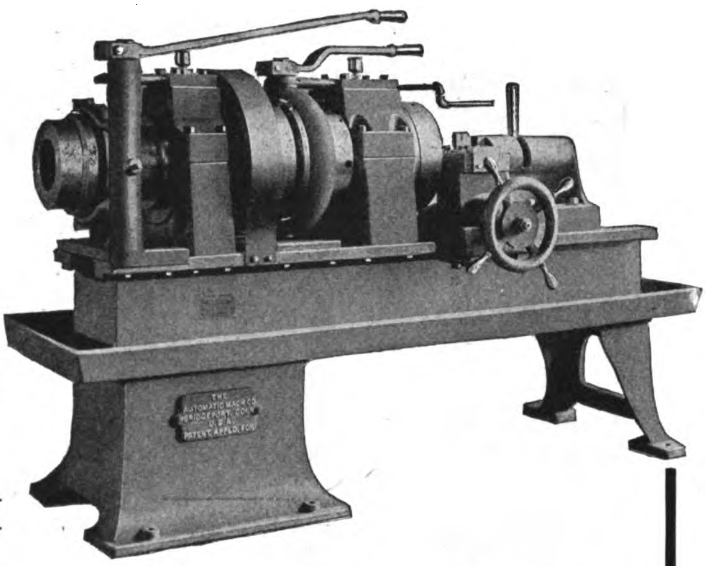
If you had fingers of steel—long, slim and strong which could reach down into the flutes of a broken tap, stuck fast in the work the problem of getting the tap out would be easy. You'd merely twiist—and out it would come.

That's the principle of the **Walton Tap Extractor.** The crucible steel fingers of this strong device go down into the flutes, grip the broken end and enable you, operating a wrench on the squared outer end, to back the tap out quickly and easily, without injuring the thread.

When such a time, labor and money saving device exists, why be without it a day longer? Yours on 60 days' trial.

THE WALTON COMPANY
HARTFORD, CONN.

Easy On The Workman



"The Automatic"

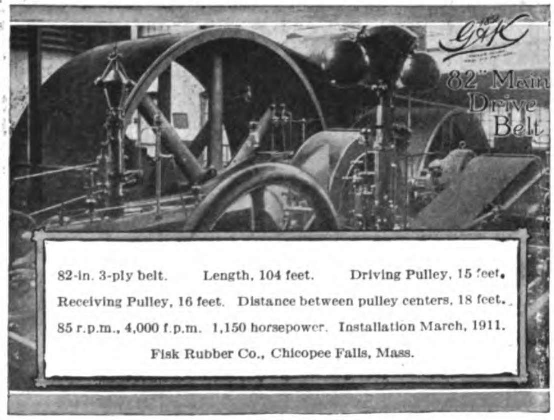
Cutting-Off Machine

for copper or steel tubes is a well-made rugged machine that will increase your production.

It will help finish your contract on time. The actual time necessary for one cycle of operation on the small machine, i.e., to feed, chuck and cut-off 3 to 6 bands is less than one minute. There are three sizes—$3\frac{3}{4}$, $6\frac{3}{4}$, 11 in.

Write for full details.

The Automatic Machine Co., BRIDGEPORT, CONNECTICUT



One Inch or Eighty-Two Inch

Machine Belt or Main Drive Belt. For any service and every service, G & K Belts give absolute satisfaction.

Because like the Fisk 82-in., all G & K Belts are carefully constructed from leather of our own tannage, tanned slowly, uniformly and expressly for belting purposes. They possess the essential qualities of pliability, firmness with minimum stretch, great tensile strength and durability. Lastly, they are absolutely guaranteed as to quality and workmanship.

There is a G & K belt for every drive in your plant—its use means maximum production and low cost of operation. Why not let us serve you?

"CUSHMAN" CHUCKS AND FACE PLATE JAWS

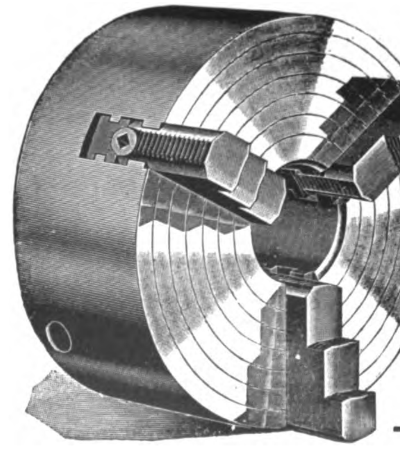
If you need a Chuck of any kind let us show you what we can furnish. We have a very complete line of

LATHE CHUCKS and DRILL CHUCKS

We also manufacture Portable Jaws for large face plates and tables.

Let us send you our catalog describing Chucks for all requirements.

THE CUSHMAN CHUCK CO., Hartford, Conn.



Geared Scroll Combination Chucks

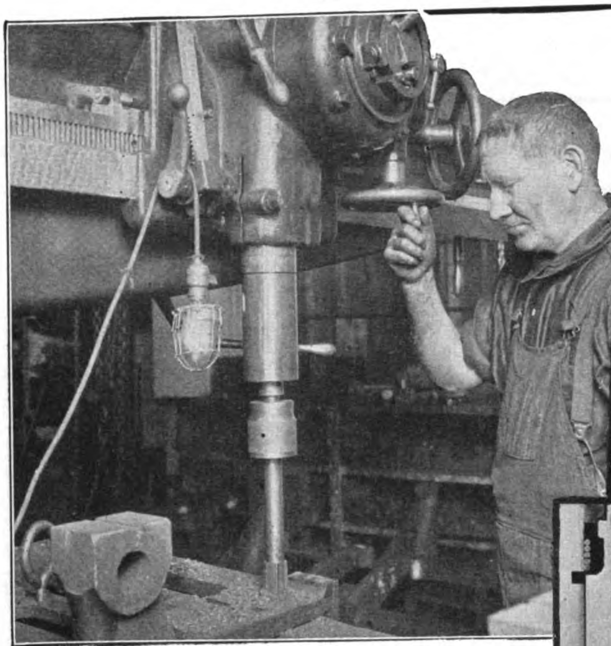
Each jaw is reversible and may be independently adusted by its separate screw. It is not necessary to throw any combination device "in" or "out" to make the chuck "Universal" or "independent," for the wrench may be directly applied to Scroll or Screw Mechanism, as required. These chucks are specially convenient for holding duplicate work by a previously finished surface. **Let us send you our complete catalog on chucks.**

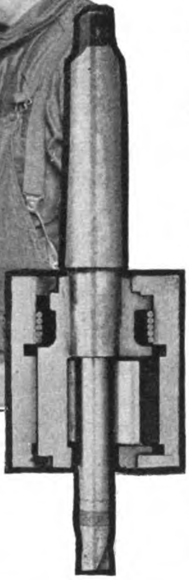
D. E. Whiton Machine Co.

New London, Conn.

Sole European Agents—Selson Engineering Co., Ltd.
"Whiton" Chucks sold and kept in stock by principal dealers all over Europe.

In Cleveland—





Before the workman reamed this 2-in. hole it was drilled—the tool change took less than 2 seconds—because he didn't have to stop the spindle.

The Cleveland Automatic Machine Co. is daily demonstrating the efficiency and versatility of

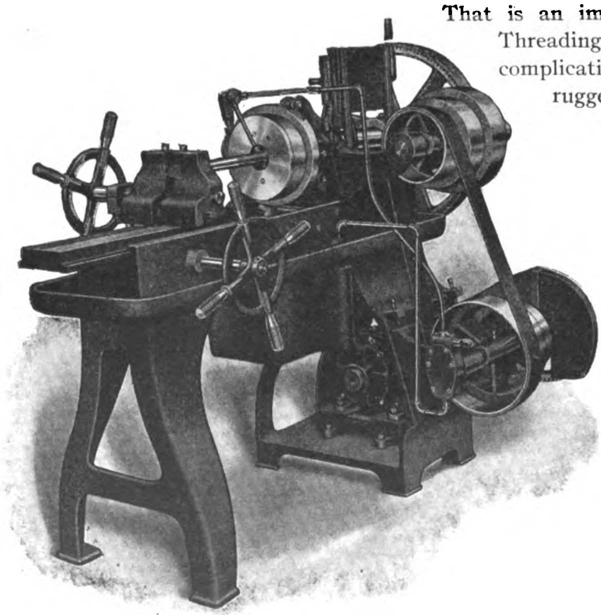
WAHLSTROM Automatic Drill CHUCKS

in the manufacture of high-grade automatic machinery. Operating a 2-inch straight shank reamer in a 1-inch chuck as pictured here is but one way in which The Wahlstrom Chuck is unusual—it is positively driven, self-centering, wide in tool range and thoroughly automatic.

There's another style Wahlstrom chuck which will hold W T S tools whether they have a tang or not.

Wahlstrom Tool Co.
350 Carroll St., Brooklyn, N. Y.

Anybody Can Learn to Run Them In a Few Moments



That is an important item of economy. Little Giant Threading Machines are free from time-consuming complications. The parts are all of simple design and rugged cnstruction.

Little Giant Threading Machines

with automatic opening die heads are adaptable to any work within their capacity. They are used for threading bolts, nuts and pipe.

Gears are covered with guards for protection. The equipment of each machine is on a rack by the head, in full view and easy reach. Any length of thread can be cut. Little Giant Threading Machines are furnished with motors attached as shown in illustration, when so specified.

Positions Open

Foreign

AN EXPERT in the designing of machines for manufacturing twist drills and milling cutters; only thoroughly competent men need apply. To the right man we offer a steady position for not less than three years at his own terms; New York City interview. P866—Am. Mach.

Cuba

STRUCTURAL DETAILER wanted for structural shop in Havana, Cuba; must be fully experience, rapid and accurate on mill building work; state experience, references and salary at once; good position for right man. Address American Steel Co. of Cuba, Box 654, Havana, Cuba.

Connecticut

A MAN thoroughly competent to take charge of automatic screw machine department wanted. Address, stating experience, wages expected, etc., P836—Am. Mach.

District of Columbia

A-1 LATHE HANDS on close and accurate work for chasing and finishing of threads; mechanics only are wanted. Apply Employment Dept., P. O. Box 1812, Washington, D. C.

Illinois

SUPERINTENDENT of factory wanted engaged in the manufacture of oil and gasoline engines; must be familiar with modern methods of manufacture, active, tactful, a close student of human nature and a natural leader; exceptional manufacturing men, even though not actively engaged in gas-engine work, are encouraged to reply; position offers a splendid opportunity for one who can qualify; give complete experience. P653 —Am. Mach., Chicago.

EXPERT in the heat treatment of all kinds of steel; a liberal salary and permanent position to one who can qualify. P814—Am. Mach., Chicago.

Indiana

FIRST-CLASS TOOL AND GAGE MAKERS wanted, accustomed to close, accurate work. Apply the Stenotype Co., P. O. Box 814, Indianapolis, Ind.

Kansas

FIRST-CLASS FOREMAN wanted for snap work department in a large foundry; good opportunity for advancement for a man who will be able to handle men to advantage; must understand both floor and machine work; advise present position, giving references and salary expected. P843—Am. Mach., Chicago.

Massachusetts

FIRST-CLASS JIG AND GAGE MAKERS wanted; only those accustomed to close work need apply. Walter H. Wade, 311 Atlantic Ave., Boston, Mass.

Michigan

ASSISTANT FOREMAN wanted for assembly department on high-grade gasoline engines; also machine-tool operators and tool makers; 8 hours a day. P840—Am. Mach., Chicago.

MACHINISTS—Young men with some machine-shop experience, to learn operating die-cutting machines in Michigan; write age, experience, salary. P842—Am. Mach.

Missouri

THE WAGNER ELECTRIC MFG. CO.'S ATHLETIC ASSOCIATION wishes to add to its boxing and wrestling talent, and will find room for good, clean amateur talent or promising material, who are either tool makers, machinists or automatic machine operators. Address C. L. La Barge, Secretary Athletic Association, Wagner Electric Mfg. Co., St. Louis, Mo.

New Jersey

ASSISTANT FOREMAN for department in shop manufacturing electrical appliances; must be thoroughly experienced on lathes, grinders, milling machines, familiar with piece-work system and modern shop methods, able to break in unskilled help. If you desire a permanent position write fully about your experience, age, nationality and what salary you expect. "Foreman," P846—Am. Mach.

DRAFTSMAN wanted on multi-color press design; state experience, age and expected salary. P809—Am. Mach.

New York

EXPERIENCED OXY-ACETYLENE WELDER wanted. In answering please give experience, wages expected and references. Ingersoll-Rand Company, Painted Post, N. Y.

BLACKSMITH AND TOOLDRESSER wanted, man thoroughly competent to heat and harden high-speed and carbon steels. In answering give references, experience and wages desired. P221—Am. Mach.

COMPETENT CLERK for order and traffic dept. wanted; experienced in iron and steel, particularly tool steels and alloy steels and specialties preferred; to receive attention state age, experience and wages expected. "Opportunity" P855 —Am. Mach.

MACHINISTS to learn operating die-cutting machines and eventually act as demonstrators, United States; also some for Europe; write age, experience, salary. P841—Am. Mach.

TOOL MAKERS wanted on jigs, fixtures and gages; highest wages and steady work; call or address Neptune Meter Co., Jackson Ave. and Crane St., Long Island City, N. Y.

TOOLMAKERS and experienced machine operators wanted; steady work and good pay. In answering please state experience or apply in person if possible. Ingersoll-Rand Co., Painted Post, N. Y.

PLANT MANAGER wanted for Ohio factory; 300 hands; iron and brass finished products; no foundry; a high-grade executive required with ability to handle men, assume entire management and with qualifications beyond superintendent. P 823—Am. Mach.

DIE MAKER experienced in round die work for friction top cans; steady work. In answering please give experience, wages expected and references. P856—Am. Mach.

Ohio

PLANT MANAGER wanted for Ohio factory, 300 hands; iron and brass finished products; no foundry; a high-grade executive required with ability to handle men, assume entire management and with qualifications beyond superintendent. P864—Am. Mach., Chicago.

Pennsylvania

MECHANICAL DRAFTSMEN, layout men, detailers and tracers. Address Chief Clerk, Engineering Dept., Westinghouse Electric & Mfg. Co., East Pittsburgh, Penn.

ASSISTANT FOREMAN wanted for iron foundry; man experienced on heavy work; must be able to furnish references. State experience, age and salary expected. Mesta Machine Co., P. O. Box 1124, Pittsburgh, Penn.

ASSISTANT FOREMAN wanted for steel foundry; must be competent man on heavy work; state age, experience and salary expected; give references. Mesta Machine Co., P. O. Box 1124, Pittsburgh, Penn.

MECHANICAL DRAFTSMAN wanted; experienced in paper-mill machinery; none others need apply. P867—Am. Mach.

MOULDER FOREMAN wanted to take charge of iron roll department; state age, experience and salary expected; give references. Mesta Machine Co., P. O. Box 1124, Pittsburgh, Penn.

EXPERIENCED MAN wanted to take charge of jarring machines in foundry doing heavy work; state experience, age and salary expected; give references. Mesta Machine Co., P. O. Box 1124, Pittsburgh, Penn.

FIVE MECHANICS to head machinery erecting gangs; unmarried, sober and reliable men wanted, with knowledge of boiler work preferred; wages $100 month. P788—Am. Mach.

MACHINE DESIGNER for boiler shop wanted; structural shop and ship-yard machinery; permanent position; applicant state fully experience. P853—Am. Mach.

PRESS ROOM FOREMAN wanted, familiar with sheet metal manufacturing, particularly drawing brass tubes; must have executive ability; state age, past experience, where now employed and wages expected; plant in central Pennsylvania; excellent opportunity for the right man. P835—Am. Mach.

Rhode Island

FOREMAN GRINDER wanted to take charge of department on automobile parts; experienced in all branches of grinding on various makes of machines, with ability to handle help and get maximum production; state age, experience and pay expected. P865—Am. Mach.

Tennessee

MECHANICAL ENGINEER wanted; one who is thoroughly familiar with steam engine and gasoline engine design, also steam boilers and a general line of machinery; permanent position for right party; give full experience, reference and salary expected in first letter. P815—Am. Mach.

West Virginia

Less than 2% of men selected through us in 1914 were discharged for any cause other than completion of work. Note high employment efficiency. Send detailed description of men needed—we do the rest.

EMPLOYERS' REFERENCE & BOND ASSN., INC., Lapham Bldg., Providence, R. I., procures capable engineers and executives to meet your needs.

H. H. HARRISON & CO., Association Bldg., Chicago, registers high-grade manufacturing executives, technical, semi-technical and commercial men. Forward complete data of requirements for immediate attention.

CORRESPONDENT

THE UNDERSIGNED plans and conducts correspondence for positions in technical, manufacturing and professional lines for $2,500 to $15,000 men exclusively; complete privacy assured; no commission charged; only service fee and postage. Send name and address only, in confidence, for prefatory details. R. W. Bixby (Established 1910), 81 Niagara Square, Buffalo, N. Y.

ASSOCIATION

FIRST-CLASS MACHINISTS, tool makers, die sinkers, lathe, planer, drill press, screw machine, boring and milling machine operators, wood and metal pattern makers, brass polishers, buffers, finishers, millwrights, hammermen and blacksmiths, who wish to increase their opportunities, to register with the free employment department of the National Metal Trades Association, 1021 Peoples Gas Bldg., Chicago, Ill.

Positions Wanted

MECHANICAL ENGINEER, 20 years' experience design and production, machine tools, cranes, hydraulic machinery, gas engines, small tools, etc., desires change; now employed as superintendent. PW862—Am. Mach.

Canada

SUPERINTENDENT or general foreman by a technical graduate with 12 years' practical experience; experienced on design of tools and machining of 8- and 9.2 shells; can lay out plant. PW859—Am. Mach.

Illinois

SUPERINTENDENT—Mechanical engineer at present employed as assistant superintendent in plant employing approximately 400 men desires change about July or Aug. 1; age 35 years, a hustler and thoroughly familiar with modern manufacturing methods; capable of estimating contract work, buying raw material and getting out work in specified time; can take complete charge of office and factory; experience 15 years marine engines, air compressors, general and special machinery, all kinds of gearing and tools; location immaterial; references. PW824—Am. Mach., Chicago.

MECHANICAL ENGINEER, university graduate, familiar with modern production methods, national experience, very many lines, who has constructed hundreds of new and special machines, who possesses the necessary experience, judgment, education, imagination, punch and power to achieve results, invites correspondence from parties who need a strictly high-class engineer for consultation, invention, designing, development, etc. PW847—Am. Mach., Chicago.

Indiana

AS EXECUTIVE or factory manager by tactful, progressive and tenacious man of experience and excellent record, now employed; systematic production understood, modern methods appreciated and commercial necessity grasped; interested in high-grade, permanent position only; available 30 to 40 days. PW838—Am. Mach.

Maine

EFFICIENCY ENGINEER, young man, technical graduate; experience in time-study work, costs, designer and neat draftsman of automatic machinery; transmission machinery, factory and mill buildings. PW861—Am. Mach.

Michigan

GENERAL SUPERINTENDENT or production manager, practical and technical; 15 years' responsible executive positions; experience: automobiles, heavy steam and gas engines, machine guns and munitions; any accurate interchangeable work with modern production methods. PW857—Am. Mach., Chicago.

New Jersey

GENERAL FOREMAN or foreman, 20 years' experience, 11 years as executive; positively can make good; reference. PW851—Am. Mach.

New York

ASSISTANT SUPERINTENDENT, production, or mechanical engineer; expert on interchangeable manufacture, rapid production, modern efficiency methods; plant maintenance; highest references relative to character, executive and productive ability. PW845—Am. Mach.

BUSINESS OR SALES MANAGER wants connection with machinery manufacturer who would consider the manufacture of several special machines; especially for South American trade; advertiser worked up through machine and pattern shops to five years designing and drafting machinery to traveling salesman, sales manager and business manager; might invest few thousand in a year or so; will give and expect good credentials. PW854—Am. Mach.

DESIGNER AND DRAFTSMAN with machine-shop practice and graduate engineer, inventive ability, desires position where these qualifications are essential. PW839—Am. Mach.

DRAFTSMAN, technical graduate, American; six years' experience arrangements and detailing electrical and mechanical. PW848—Am. Mach.

SALES ENGINEER, production engineer or publicity by mechanical engineer; can advise as to layout, machines and equipment. PW794—Am. Mach.

MECHANICAL ENGINEER and designer of many years' experience, specializing on automatic paper-handling machinery, desires position as high-class designer and developer of intricate automatic machinery and devices; wishes to work practically independent of drafting room; New York City or vicinity. PW849—Am. Mach.

MECHANICAL ENGINEER, college graduate, good executive and salesman, large experience in power transmission, conveying, elevating and general machinery, foundry work, etc., open for position. PW844—Am. Mach.

MACHINIST — First - class tool - die maker, experiment tool designer, technically trained, 20 years' wide experience, best references, wishes position as foreman. PW827—Am. Mach.

I HAVE AN UNDENIABLY SUCCESSFUL RECORD as an organizer of factories and handler of men; am a practical mechanic of large experience in many varieties of manufacture. I am now giving satisfactory service to a large corporation in the East, but for strictly personal reasons wish to make a change to the West or Middle West; can furnish references of the most convincing kind. PW821—Am. Mach.

FOREMAN, German nationality, 30, wants change; 12 years' experience in manufacturing small interchangeable parts, assembling of small machinery and the handling of male and female help to best advantage; A-1 references; salary expected, $28 per week. PW858—Am. Mach.

POSITION AS TOOLROOM FOREMAN wanted by American, age 35; wide and varied experience. Details furnished on addressing PW860—Am. Mach.

Ohio

A FIRST-CLASS MACHINE TOOL SUPERINTENDENT, at present employed by a well-known company, wishes to make a change; has had a general experience in the manufacture of all kinds of machine tools; also able to supervise the designing; replies confidential. PW 746—Am. Mach., Chicago.

AS MANAGER or general superintendent by a man of wide and successful experience in the supervision and management of plants consisting of machine shops, foundries, blacksmith, woodworking, sheet metal and contributing departments, including main office; will guarantee an open-shop policy without labor troubles; straight salary or commission. PW 805—Am. Mach., Chicago.

Pennsylvania

SUPERINTENDENT OR WORKS MANAGER, now successfully in charge of manufacturing plant embracing machine shop, foundry, smith shop, woodworking department and all other manufacturing departments, including factory accounting, production and planning departments; experienced in designing and production of special tools, jigs, etc., including organizing and systematizing along modern producing lines; middle-aged and married; will consider change and can give satisfactory reasons for same. PW 834—Am. Mach.

Wisconsin

DRAFTSMAN, young man, experienced in shop work and mechanical drafting, desires position as detailer or layout man; good references. PW850—Am. Mach., Chicago.

Wanted

TWIST DRILLS, CARBON STEEL, jobbers' lengths—we are open to purchase large quantities continuously, send price list, discount and cash terms to Wm. Hall (Sheffield), Ltd., Alma Works, Sheffield, England.

AGENTS AND SALESMEN

FACTORY AGENTS for the Fractiometer; adds and subtracts, shows the decimal equivalent quicker than figures are written; $1\frac{5}{8} - \frac{41}{64} = \frac{63}{64} = 0.984375$; great labor saver for designers, draftsmen, machinists and others; sent on approval; price 50c. Fractiometer Co., Rochester, N. Y.

TOOL STEEL SALESMAN wanted for New England; technical graduate familiar with machine-shop practice preferred. Address with full particulars. W852—Am. Mach.

SALESMEN wanted by progressive concern; must be a mechanic, acquainted with the latest shop methods and believe absolutely in the limit system; exceptional opportunity for the right man; state age and experience. W810—Am. Mach.

SALESMAN wanted, having experience in tool steel and alloyed steels preferred; opportunity for advancement. In order to secure attention, application must positively state age, experience and salary expected. "Permanent," W816—Am. Mach.

EXPERIENCED MACHINE TOOL SALESMEN wanted; must be hustlers who have proven ability to get business; give experience and reference of former employers. W863—Am. Mach., Chicago.

PUNCH PRESS TOOLS, jigs, fixtures, etc. Taylor-Shantz Co., Rochester, N. Y.

MACHINERY, small or medium, designing, models, dies or jigs, 1 to 1,000 or more, right to your blueprints. Estimates submitted. Berggren & Pearson Machine Co., 221-227 Canal St., New York City.

WE ARE IN POSITION to take on additional work for the following machines: 36-in. Fellows gear shaper, 24-in. Gisholt lathe, 2-in. hand screw machine, 3x36 Jones & Lamson and 2 horizontal boring machines. The Sinclair-Scott Co., Baltimore, Md.

MECHANICAL ENGINEERING AND MACHINE DESIGN—Do you want a special machine peculiarly adapted to your product and more economical than the standard machine? Wide experience in work of this character enables me to name time estimates which can be fulfilled. W. L. Schellenbach, 520 First National Bank Bldg., Cincinnati, Ohio.

FIRMS WANTED to take on extremely close contract work on small parts suited to screw machines, lathes, J. & L. millers, and internal and external grinders. In replying, state machines available. W806—Am. Mach.

TOOL AND DIE WORK wanted; also work for a plain Morton grinder, size 6x36". Address American Standard Motion Picture Machine Co., 168 S. Boulevard, New York City.

Additional Contract Work Advertisements on pages 176-181 inc.

Miscellanoues

GET A "LAST WORD," the Test Indicator Par Excellence. Described in Nov. 18 issue, "American Machinist." H. A. Lowe, 1374 E. 88th St., Cleveland, Ohio.

Patent Attorneys

PATENTS. C. L. Parker, patent attorney, McGill Bldg., Washington, D. C. Inventor's handbook sent upon request.

Business Opportunities

NEW FIREPROOF FACTORY, equipped with electrically driven modern machine tools, also woodworking machinery; 100 miles from New York; transportation via N. Y. C. R.R., B. & A. R.R. and Hudson River; private siding; interest in business if desired. BO349—Am. Mach.

WATER POWER for sale, 500 hp. combined with an established business over 30 years; a going concern with best reputation; no labor trouble. Address Langdon C. Foster, Fulton, N. Y.

For Sale

CAMDEN, N. J., immediate occupancy, suitable for war orders or any business; brick buildings, 93,000 feet of floor space, with very fine power plant; 4.6 acres on water front, Philadelphia lighterage limits; price a decided bargain; substantial mortgage. L. N. Creighton, Agent Bayonne, N. J.

HEAVY-DUTY DRILLING MACHINE; drawings, patterns, jigs and stock of parts; fully developed and ready for manufacturing. FS772—Am. Mach.

16 LB. ASSORTED SPRINGS, light and heavy coils, 75 varieties for repairs and experiments, $2. Hubbard Spring Co., Pontiac, Mich.

Second Hand Machinery

VONNEGUT Machinery Co., Indianapolis, Ind.

Chucking Machines

58 Potter & Johnson No. 6A automatic, new.—DAVIS.

Cold Saws

3 No. 5—6" Nutter-Barnes.—C. & F. CO.

Cold Saw Machines

18 Newton No. 500 with 20" inserted tooth blades.—DAVIS.

Drilling Machines

26" Rockford, with sliding head, back gears, power feed.—DAVIS.

4 Henry & Wright No. 1 style K, new; 12 Colburn size D2, new; 25 Colburn size D4, new; 1—24" Hoefer, new.—DAVIS.

[Radial]

36" Dreses radial cone drive, quick-return tapping attachment.—DAVIS.

3' Mueller, 5' Dreses.—C. & F. CO.

Four Myers bench drill presses with chucks (new); Aurora 20" swing, vertical drill press, power feed, back gear, $150.—MANN.

Gear Cutters

30" Flather, fine condition.—Dreses Machine Tool Co., Cincinnati, Ohio.

Generators

180-kw., 3-ph., 220-V., 60-cy., 514-r.p.m. generator with exciter.—The Watson-Stillman Co., Aldene (Roselle P.O.), N. J.

Grinders

12"x42" Landis, universal.—DAVIS.

B. & S. No. 2 surface.—PARMELE.

No. 16 Brown & Sharpe plain, 10"x72"; Norton 10"x50" plain; Warner & Swasey, double spindle, internal.—C. & F. CO.

Universal tool and cutter grinder—Wells No. 190, complete with all attachments, new.—DAVIS.

Kettles, Soda

2—40-gal. gas-heated soda kettles, in good condition; make us an offer.—Wagner Electric Mfg. Co., St. Louis, Mo.

Keyseaters

1 No. OO Baker, $185.—CINCINNATI.

Lathes

34" Gisholt with 4" hole.—VONNEGUT.

19"x6' Porter, with three-step cone, double back gears.—DAVIS.

Advertisers' Names are abbreviated in most of these items. Complete names and addresses head the list.

Draper 18"x18' lathe, turret on shears, with power feed, 2⅛ hole in spindle.—PARMELE.

14"x6' LeBlond QCG, motor drive; 14"x 6' Prentice QCG, C.R.; 16"x8' Prentice, geared head, QCG; 19"x8' Reed, C.R.; 26" x12' Reed, C.R.; 30"x10' Fifield, triple geared.—C. & F. CO.

1—16"x8' Barker, new; 38-16" Fairbanks-Morse, new.—DAVIS.

Bradford 24" swing x 12' engine lathe, plain change gear, 2" hollow spindle, comp. rest, form 4½" belt; new Morris engine lathe, 18"x8' double back gear, semi-quick change, comp. rest, hollow spindle; Lodge & Davis 18"x10' engine lathe, taper attachment, plain change, hollow spindle, comp. rest.—MANN.

Milling Machines

No. 3½ Garvin plain, with countershaft, $400.—A. H. Wadell, Rahway, N. J.

1 No. 2 LeBlond plain, 3-step cone pulley, single back gear, quick change gear for feed, good condition, $775; 1 No. 3 Le Blond plain, 3-step cone pulley, double back gear, quick change gear for feed, good condition, $1,050.—HIMOFF.

Planers

Slightly used 42"x42"x26', 4 heads, 4 speed gear box on housings and motor drive; fine condition.—Whitcomb-Blaisdell Machine Tool Co., Worcester, Mass.

1—24"x24"x6' L. & D.—BLESSER.

Whitcomb, crank; 30"x30"x8' Flather, 2 heads; 48"x48"x20' Putnam, 2 heads.—C. & F. CO.

40"x40"x12' New Haven with one or two heads.—DAVIS.

Presses

Punch presses—A variety from 900 to 9,000 lb. in weight.—VONNEGUT.

Screw Machines

[Automatic]

6—⅝" Cincinnati, $800 each.—CINCINNATI.

One 4¼" Cleveland auto.—BLESSER.

¾" and ⅞" 4-spindle National-Acmes; No. 55—1⅝" 4-spindle National-Acme.—C. & F. CO.

6 No. 3 Stecher, new.—DAVIS.

Shafting

12,000 to 15,000 lb. 1⅝" cold roll shafting at less than regular present price, mill lengths. Address the Dairy Cream Separator Co., Lebanon, Ind.

Shapers

20" Hendey, geared friction.—DAVIS.

20" Smith & Mills, gear box drive; 24" Hendey, friction; 15" American Tool Works Co.'s, crank.—C. & F. CO.

Shears

1—60" type I-H Collier Smith rotary shear.—VONNEGUT.

Traveling Cranes

One 40' span, 15-ton electric traveling crane, D.C., 220 volts, hoist 12 hp., trolley 7 hp., bridge 10 hp. This crane has just been removed to make way for a new one. Hoisting motor should be renewed. —Murray Iron Works, Burlington, Iowa.

Turret Lathes

2"x24" J. & L. cone head; 1¼" Pratt & Whitney wire feed screw machine, geared friction head, power feed to the turret, latest pattern.—C. & F. CO.

22" Libby full swing side carriage turret lathe; excellent condition; including two motors and tools.—COFFIN VALVE CO., Neponset, Boston, Mass.

2"x24" J. & L. cone-head-type, motor driven, with bar equipment.—DAVIS.

12"x5' Wells with 7¼" three-jaw universal chuck and six-hole turret.—DAVIS.

WANTED

36" Niles pulley lathe, gear feed preferred; must be in good condition. Union Iron Works, Decatur, Ill.

We need immediately a planer type surface grinder for finishing drop forging dies. Capacity 20"x20"x4' more or less; need not have oscillating attachment. We also need 20" back geared Gould & Eberhardt shaper. Tools must be in strictly first-class condition and price reasonable.—Bonney Vise & Tool Works, Inc., Allentown, Pa.

To Advertisers of Second Hand Machinery

With the July 6th issue we will discontinue the "list" form of advertising as above and substitute the sale of space by the "inch."

This will give each advertiser an individual space in which to display his advertisements of Second Hand Machinery, For Sale or Wanted.

The following rates will apply:

1 in.	$3.00	15 in.	2.70 an in.
4 in.	2.90 an in.	27 in.	2.60 an in.
8 in.	2.80 an in.	50 in.	2.55 an in.

(Rates for larger spaces furni hed on request.)

$400,000 Worth of Machine Tools

FOR IMMEDIATE DELIVERY

Most of them only about a year old

Our Entire Equipment For Sale consisting of a complete line of machinery suitable for the manufacture of 3 to 6-inch shells or general manufacturing purposes, including:

Lathes	*Planers*
Jones & Lamson's	*Thread Cutting Machines*
Gridley's	*Grinding Machines*
Shapers	*Also Some Large Heavy Tools*

Send for Catalog, listing same in full, or better still, come to Providence and look the machines over in our plant.

PROVIDENCE ENGINEERING WORKS - Providence, R. I.

FOR SALE

Engine Lathes 21-in. Swing, 8 ft. 6-in. bed with Turret.

Hurlburt & Rogers 6-in. Cutting-Off Machines.

These are new machines and have never been used. They were purchased in excess of our requirements.

Prices will interest you. Will send photograph.

Address your inquiry to the Purchasing Agent, Mead-Morrison Mfg. Co., East Boston, Mass.

Let Us Solve Your Problems

Successful and economic production of interchangeable parts depends greatly upon accuracy, permanency and type of tools, dies, jigs, fixtures, gauges, etc. Our modern and thoroughly up-to-the-minute factory gives us one of the

Finest Tool Rooms in Country

We employ only the highest grade skilled specialists, tool and die makers; we have the latest and most improved machinery; these facts together with our method of production enable us to turn out high-grade work most economically.

Send for quotations—mail us blueprints for bids—forward samples of work and note our charges and the grade of work.

When we say we will deliver upon a certain day, it will be delivered that day—not the following. One trial will convince you. Try us.

KRASBERG MFG. COMPANY
412-420 Orleans Street - - Chicago, Ill.

Here's the Work We Do—

Jigs, Fixtures and Gauges. Tool work and light machine work of every description.

Here's How We Do It—

Accurately and economically Better have our estimate for future reference. Send us your blueprints and specifications now.

F. C. Sanford Manufacturing Co.
Bridgeport - - Connecticut

Engineering Service To Manufacturers

You need perhaps, jigs, gages, fixtures and other special tools for your plant. We can help you here. We design and build all kinds of special machinery. Our experience with manufacturers of fuses and war munitions may be of interest to you.

Write us for particulars.

The Carroll Engineering Co., Dayton, O.

SMALL MACHINES AND PARTS MANUFACTURED ON CONTRACT

We have an up-to-date machine plant, with every facility for making small machines, parts, novelties, etc., in quantities.
We want to do the manufacturing—you do the selling.
Submit your blue prints to us and we will tell you what we can do.

Contract Work

Our Men are not "Agin the Management"

If you will consider a moment you will appreciate that this means that a higher class of workmanship must result.

Every man in our plant constantly uses his best endeavors to produce the finest in whatever he does, be it a jig, fixture or special machine, and to perform this duty in a reasonable length of time.

Rush is a word that our men know often spells disaster—but on the other hand their chief interest is not in how fast the clock runs in combination with how slow they dare feed a machine tool.

These men will design and build your jigs, fixtures and special machines better and in the long run quicker.

Don't you want them for your work?

66 years making every kind of STEEL STAMPS AND DIES

FOR EVERY MARKING NEED

Have You Our Catalog?

Jas. H. Matthews & Co. Inc. PITTSBURGH, PENNA.

SPECIAL TOOLS

We make dies, jigs and fixtures. Our work is of the highest quality and our prices are very reasonable. We employ highly skilled die-makers and our equipment and shop conditions are practically perfect.

A trial will prove this.

NELSON TOOL CO, Inc.
781-783 East 142d Street New York City

THE H·E·HARRIS ENGINEERING CO·
MANUFACTURING ENGINEERS

Our large well equipped shop is making the most accurate tool and gauge work at lowest cost.

BRIDGEPORT - CONNECTICUT

Light and Heavy Machine Work

We are equipped for and prepared to do all classes of light and heavy machine work, also cutting of gears and pinions.

Promptness and accuracy guaranteed. Prices reasonable. Correspondence solicited.

The Cambridge Machine Co., Cambridge, Ohio

Contract Work

"W & B" DROP FORGINGS

We make a specialty of the highest grade Drop Forgings. Our exceptional capacity and equipment insure accurate forgings and prompt delivery. Send us models and blue prints and permit us to estimate on your requirements.

The
Whitman & Barnes Manufacturing Co.
Established 1854
120th Street CHICAGO, ILL.

UNDERWOOD SERVICE

means the quick and inexpensive repair of that broken-down engine.
A letter, phone call or wire brings it to your door—men and tools—**quick.**
The name "Underwood" is almost a guarantee of uninterrupted operation since the Underwood Wrecking Crew is always ready for the emergency job.

Read "Helpful Hints."

H. B. Underwood & Co., Philadelphia, Pa.
Established 1870

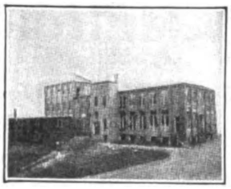
Castings

Engine Bases
Cylinders
Fly Wheels
Turbines
Anything—

Large massive castings weighing up to 150,000 lbs. each are our specialty. We'll handle any job you put up to us in molding iron or semi steel of the highest quality and greatest strength. Let us quote you—our experience is at your service.

Foundry Department
Farrel Foundry & Machine Co., Ansonia Connecticut

We Can Help You



to attain better and quicker results from your **special machines** by building them for you in any quantity in this modern factory at a much lower cost than you could possibly secure in your own shop.

Our engineers, machinists and draftsmen are men trained in their line of work. Special machinery, machine parts, dies, jigs, fixtures and tools designed and built to your order—in any quantity. Special rates on contracts.
Send blueprints for preliminary cost and time estimates. **Write us today.**

Fitchburg, Mass.

Machine Work on Contract

Light and Heavy Machines.
Gear Cutting

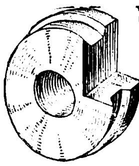
Send us blueprints and we will gladly furnish estimate.

The New England Machinery Co., New Haven, Conn.

ACCURATE PUNCHES AND DIES

18 years' experience in the making of small accurate punches and dies have given us a complete knowledge of the business. Plain or sub-press—if high-class work is desired, you will profit by sending your inquiries here.
THE SIMPLEX TOOL CO., Woonsocket, R. I.

TOOL ROOM WORK



We make a specialty of Form Cutters, Gauges, Jigs and Fixtures of any or every kind. *References.* Some of the largest concerns in the country. Write us today.

Geo. W. Dover Parts Co.
Providence, R. I.

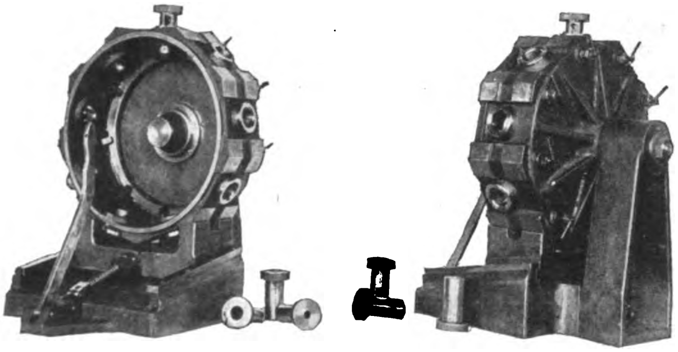
Saving Costly Mistakes

.. very small percentage of difference in the composition or hardness of your steel may have serious consequences.
Only the most exact and searching tests can reveal the error, but it is there all the same.
Souther Inspection Service protects you from these and other troubles.
Let us tell you how.

HENRY SOUTHER ENGINEERING CORP.
Hartford, Conn.

Contract Work

TRADE MEHL MADE MARK



At first they decided to sacrifice Quality for speed—

So they withdrew a fixture order that had been placed with us and turned it over to another shop—

But the order was returned to us soon after, and we have done all of that company's work since.

DO NOT infer that Mehl-made Jigs, Fixtures, Dies, Gages and special machinery require extra time in the making—

On the contrary they are built in a minimum of time—quality considered.

But this quality is the standard by which we would have them judged—quality insured by expert workmen, a model shop ideally appointed, and a fund of experience in the making of better tools.

Serve your best interests—send that next order here.

Try us on our Small Screw Machine Products up to 1 inch diameter.

Mehl Machine Tool & Die Company

Roselle, N. J.

Special Tool Work

is the backbone of our main line and we are especially well equipped in every division of our plant to execute all orders with speed and accuracy. We have the men—the machines—the ability.

If you are considering placing orders for special tools and machinery write for our booklet.

SPECIAL MACHINES

Machine parts in large or small quantities.

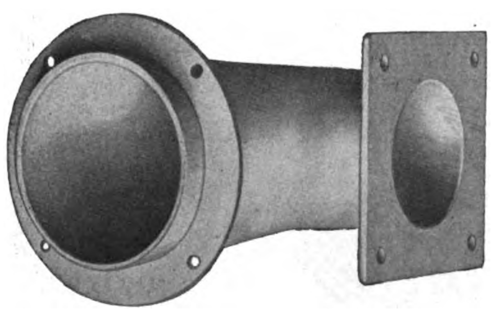
The Steel Products Engineering Co.
Springfield, Ohio

Stewart

Toot! Honk! We are making millions of automobile parts for high-grade machines—better castings at less cost—of aluminums and white brasses. And thereby we have saved thousands of dollars for others. Let us show you how you can obtain better castings and at the same time cut your production costs. Send today for particulars and interesting booklet.

Better diecastings

Stewart Manufacturing Company
Wells Street Bridge :: Chicago



This talking-machine part is now die-cast cheaper than formerly machined from brass sand castings.

MORE than one manufacturer in close competition thanks our *"Quality* Die Castings" for the saving they afford against the cost of machine finishing.

Perhaps we can cut your production cost, too.

LIGHT MFG. & FOUNDRY CO.
Pottstown, Pa., U. S. A.

(72)

This Way Is Easier

Just immerse the wash basket of parts to be cleansed of oil, grease and chips into the Gray & Prior **Soda and Potash Kettle.**

This is the easiest way to thoroughly and economically cleanse newly made machine parts, such as screws, nuts, bolts, gears, studs, etc.

Two cents worth of common sal soda to the gallon of boiling water takes the place of expensive gasoline cleansing and eliminates all fire risk.

Write for Descriptive Circular.

Why Witt Won

A. J. Witt, Manager, Cumberland Foundry & Mfg. Co., Nashville, Tenn., was until a few months ago like hundreds of other foundries—fairly successful and contented.

He Eclipsed All Records

Business jumped—began to boom—orders poured in beyond capacity, although his castings cost more—Why? Because

With McLain's System

followed by McLain's backing his every step increased his business and profits beyond anything before thought of.

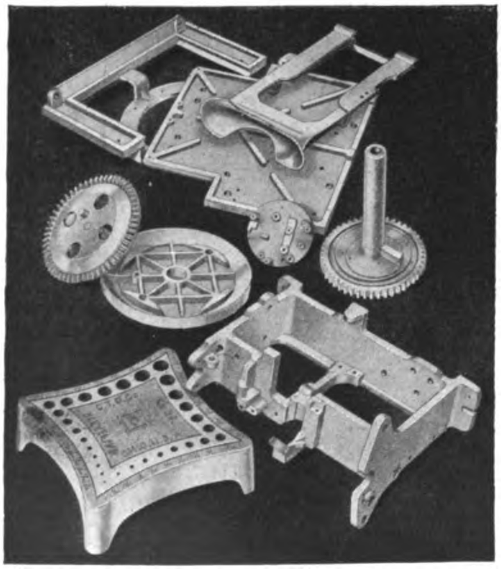
Isn't it reasonable to suppose what he has done for Witt and hundreds of others he can do for you? Why not get the whole story—free for the asking—no obligation incurred.

McLain's System

909 GOLDSMITH BUILDING, MILWAUKEE, WIS.

The Franklin Die-Casting Process

The Direct Way to Results



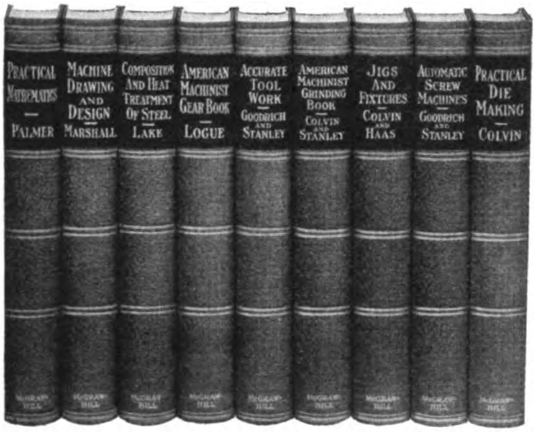
The parts shown above were produced at a saving to our customers over the usual machine methods.

We can reduce your manufacturing cost, too. Let us have your samples or blue prints for quotation.

Booklet "H" on request.

FRANKLIN MANUFACTURING COMPANY
740 Gifford Street, Syracuse, N. Y.

Especially in Machine-Shop Practice—



You Want Facts—

facts and details which must be unvarying in their practical application to the work you are doing. No experimentation must be indulged in.

When you read books you do so in order to improve upon your own methods—to increase your knowledge and earning power. There are no other incentives. Books purporting to tell how to improve methods, knowledge and earning power in the machine-shop field must necessarily be of a high standard, otherwise they could not possibly receive recognition at the hands of the machine-shop man of today, who demands accuracy, authoritativeness, conciseness.

THE MAN WHO IS EXACTING WHEN IT COMES TO MACHINE-SHOP LITERATURE WILL APPRECIATE THE **MACHINE-SHOP LIBRARY,** containing nine volumes and three thousand pages, because every page was written by a practical man. Each of the eight authors, and the hundreds of contributors, are advocates of the highest standards of efficiency in shop operation.

Any man interested in any branch of machine-shop work will recognize in the Machine Shop Library a helpful and distinct method of bringing out in detail both the simple and intricate operations—simple methods of acquainting even the apprentice with these operations which will probably not be found in any other books.

For reference or study—or both—the Machine-Shop Library will pay you back for its price in a short time. Its methodical system of making man and machine more efficient is never-failing.

We will send by parcel post prepaid the nine volumes weighing about sixteen pounds to you upon receipt of the coupon below. No advance remittance is required.

---Free Examination Coupon---

McGraw-Hill Book Company, Inc., 239 West 39th Street, New York.

Gentlemen: You are requested to send me for free examination your new Machine Shop Library, nine volumes, you to pay transportation charges. If satisfactory I will send $2 in ten days and $2 per month until I have paid your special price on the books, $16. If they are not what I want I will write you for shipping instructions, and I am to be put to no expense.

YOU *are safe when buying products advertised in the American Machinist.*

Replace Your Man-Killers With a Safe, Reliable Invention!

Wild beasts of prey are less treacherous than the man-killing setscrews and flange couplings which so often take their toll in shops and factories.

A loose sleeve, an open jumper or an overall support offers these old-fashioned contrivances their opportunity to slay or mangle your men. That can all be eliminated by the use of a horse-sense coupling—one that locks itself—locks harder as the load is increased—and has no screws, bolts or nuts to catch clothing or hair. Such a coupling is the

Bull Dog Shaft Coupling

This coupling, endorsed by the Workman's Compensation Bureau and the American Museum of Safety, is simply a smooth metal cylinder in which are two eccentric chambers each having a rolling lock that grips the shaft solidly.

BULL DOG SHAFT COUPLING TRADE MARK REGISTERED

No tools are needed to put on or take off the coupling—there is nothing to wear out—nothing to mar the shaft. It will take care of considerable error in alignment with little or no power loss.

Our free booklet with full description and sizes and prices sent to interested executives.

Reduce the Wear and Breakage of Your Costly, High-Speed Drills

"New Yankee"
Drill Grinding Machines

Will grind your drills perfectly, saving up to $\frac{2}{3}$ of your drill cost.

Most drill breakage, and a large proportion of wear, result from improper grinding. It's impossible to get the point of a drill exactly centered, with each cutting lip at the same angle—by any method of hand grinding. But with the "New Yankee" it's practically impossible to get anything but absolutely perfect grinding—a boy can do it.

Let us give you actual details on the "New Yankee" Drill Grinder—how it's built and what it is actually doing. Write to us.

Wilmarth & Morman Co.
1187 Monroe Avenue
Grand Rapids - - Mich.

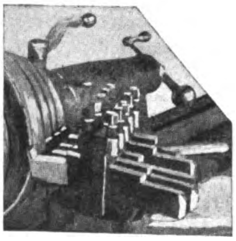
Have That Safe Feeling

IF you run up against a problem in your shop that you are not exactly sure about, ask Information Dept., American Machinist, N. Y.

TOTALLY DIFFERENT

from any other tool holder on the market, the

REX Tool Post



More than doubles the capacity of your lathe.
You can set as many Rex posts as you like, close up together, each one making a different cut *at the same time.*
This means increased output *at lower* cost so the Rex more than pays for itself in a very short time.

Write for Bulletin

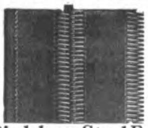
Rex Mfg. Co., Hyde Park Dist., Boston, Mass.

C·O·L·U·M·B·U·S

The massive, powerful 21-in. Engine Lathe—single purpose, heavy duty, especially adapted to fast, accurate outside turning of shells up to 9.2 in. and boring up to 6 in.

The Dunlap Mfg. Co. :: Columbus, Ohio

The Jackson Belt Lacing Machine

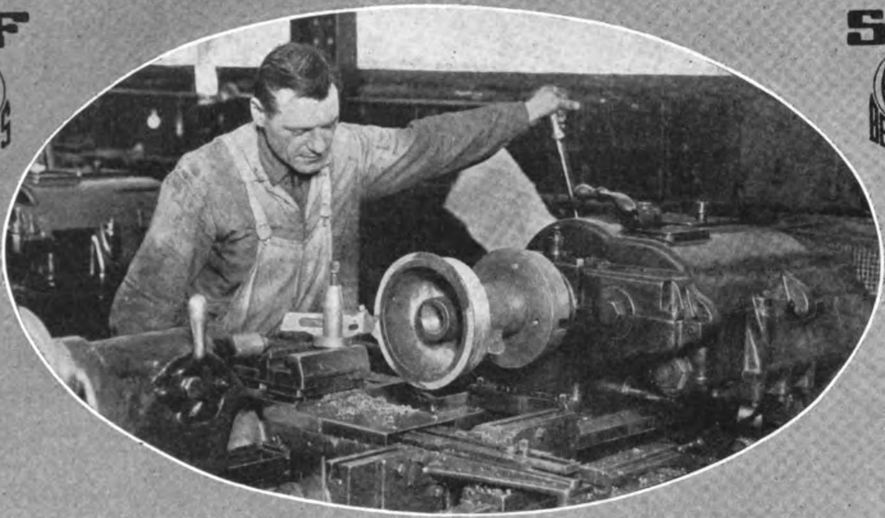


saves its cost every few months. It's light and portable and produces a joint in three minutes that will stand a tensile strength of 1900 lbs. With it one man can do in three minutes at a cost for material of one cent, what usually requires a half hour of two men's time and 10 to 12 cents worth of rawhide the old way. Write for the "Jackson Book."

BirdsboroSteelFoundry & MachineCo., Birdsboro, Penn.

SKF BALL BEARINGS

SKF BALL BEARINGS



Making It Easier For The Lathe To Do Its Work

Here you see an 18-in. Greaves-Klusman Lathe at work in the plant of the Ward Motor Vehicle Co. at Mt. Vernon, N. Y.

They write—"The SKF Ball Bearings after nine months hard work are in perfect condition."

This paragraph taken direct from this Company's letter, shows the kind of service rendered by SKF Ball Bearings.

And the service is strenuous in the extreme. The lathe is working on cast steel wheel hubs, the 10-in. diameter of drum being finished in two operations.

To quote again from the letter: "Very little time is required for oiling these machines as all the ball bearings are oiled from the gear cases."

SKF Ball Bearings are standing up to hard service in this case, as well as they do in all. Nine months steady use in a "hog for work" fails to impair their remarkable efficiency one iota.

Look for SKF. It is your guarantee of quality. It means that SKF Ball Bearing thrusts increase the accuracy of the cut and reduces the power consumption of the lathe.

Write for Bulletin No. 25 for more details.

Bolt and Nut Machinery
Acme Machinery Co., Cleveland, Ohio. Cable Address: Acme, Cleveland.
Baush Machine Tool Co., 604 Wason Ave., Springfield, Mass., U. S. A.
Stay bolt threading machines and bolt turning machines for both straight and taper bolts.
Davis Machine Tool Co., Inc., 311 St. Paul St., Rochester, N. Y.

Some of the Advantages of

SYMINGTON

Single Purpose Shell Machines

Large and Heavy Slides and Moving Parts
—to reduce vibration, maintain accuracy and original alignment, and give durability

Less Number of Joints Between Support of Tool and Support of Work
—to diminish spring of tool and work supports and increase rigidity

Less Distance Between Spindle Bearing and Ways
—to increase rigidity and accuracy

More Room and Better Support for Cutting Tools
—to make the tooling more simple and inexpensive

The operations are simplified and are performed by unskilled labor.

Boring, Drilling and Milling Machines, Horizontal
Barnes Co., W. F. & John, 1995 Ruby St., Rockford, Ill.
Baush Machine Tool Co., 604 Wason Ave., Springfield, Mass., U. S. A.
Special multiple spindle horizontal drilling machines.
Beaman & Smith Co., Providence, R. I.
Betts Machine Co., Wilmington, Del. Cable: "Bettwell."
Coats Mach. Tool Co., Inc., 30 Church St., N. Y. C.
Detrick & Harvey Machine Co., Baltimore, Md. Cable: Detharvey.
Spindle 3½" to 8". Floor type only. Motor or belt drive. All gear feeds. Rapid power traverse. Rotary tables for hand or power and universal tilting table. Screw-cutting attachment can be furnished. Any size bed.
Fosdick Machine Tool Co., Cincinnati, Ohio.
Horizontal No. 0, spindle 3⅛.
Hoefer Mfg. Co., Freeport, Ill.
Lucas Machine Tool Co., E. 99th St. and N. Y. C. R.R., Cleveland, O. Cable: Lucas, Cleveland.
Three sizes, 3", 3¾" and 4½" spindles.
For boring, milling and drilling as separate operations, or all three operations, at one setting of the work.
Moline Tool Co., Moline, Ill.
National Automatic Tool Co., 7th and S. N St., Richmond, Ind. Cable: Natco, Richmond.
Horizontal multiple spindle drilling machine. Three sizes, 2 to 150 spindles from 2 to 5 directions simultaneously.
Newton Machine Tool Works, 23rd and Vine St., Philadelphia, Penn.
Niles-Bement-Pond Co., 111 Broadway, N. Y. C.
Pawling & Harnischfeger Co., Milwaukee, Wis.
Prentiss Tool & Supply Co., Singer Bldg., N. Y. C.
Sellers & Co., Inc., Wm., Philadelphia, Penn.
Springfield Machine Tool Co., Springfield, Ohio. Cable: Montanus. Spindle and axle boring machines, 2 sizes, 7"x60" and 11"x84".
Universal Boring Machine Co., Hudson, Mass., U. S. A. Cable: "Horizontal," Hudson.
No. 3-A Universal (horizontal) boring machine has 3" main boring bar with 28" continuous feed table 24" by 48" with 36" power crossfeed. No. 3½ Universal (horizontal) boring machine has 3½" main boring bar with 30" continuous feed, 30" vertical movement. Table 30" by 48" with 36" power crossfeed.
Vandyck Churchill Co., 93 Liberty St., N. Y. C.

Boring Heads
Marvin & Casler Co., Canastota, N. Y.
Radical Boring Head Corp., 90 West St., N. Y. C.
Taft-Peirce Mfg. Co., Woonsocket, R. I.

Boring Tools
Union Caliper Co., Orange, Mass.

Western Tool & Mfg. Co., Springfield, Ohio.

Boxes, Tote (See Furniture, Machine Shop)

Broaches
Lapointe Co., J. N., New London, Conn. Cable: Lapointe, New London.
Lapointe Machine Tool Co., Hudson, Mass.
For any class of work, for use on any broaching or keyseating machine.
Send for Catalog "C."
Taft-Peirce Mfg. Co., Woonsocket, R. I.

Broaching Machines
Lapointe Co., J. N., New London, Conn. Cable: Lapointe, New London.
Five sizes.
No. 0 machine, capacity to cut keyways ¼" wide by 2" long, sq. holes ½" sq. by 1" long. No. 1 machine, keyways ⅝" wide by 3" long, sq. holes ¾" sq. by 1½" long. No. 2 machine, keyways ¾" wide by 8" long, sq. holes 1½" sq. by 4" long. No. 3 machine, keyways 1½" wide by 10" long, sq. holes 3" sq. by 6" long. No. 4, keyways 2½" wide by 20" long, sq. holes 5" sq. by 12" long.
Lapointe Machine Tool Co., Hudson, Mass. Cable: "Lapointe, Hudson."
Four sizes—No. 1, square holes up to ¾"; No. 2, square holes up to 1¼"; No. 3, square holes up to 3"; No. 4, square holes up to 4". Round or irregular shapes of larger sizes can be handled. Send for Catalogue C.

Bronze
American Bronze Co., Berwyn, Penn. 429 Ford Bldg., Detroit, Mich. Cable: Ambrocom, Phila.
"Non-Gran" high-speed bearing bronze for solid nonadjustable bronze bushings.
See advertisement on back cover.
Lumen Bearing Co., Buffalo, N. Y.

Buffing or Polishing Machines
Barnes Co., W. F. & John, 1995 Ruby St., Rockford, Ill.
Blake & Johnson Co., The, Waterbury, Conn.

Link-Belt silent chain.
Send for 112-page data book No. 125.
Morse Chain Co., Ithaca, N. Y., U. S. A. Branches: New York, Boston, Chicago, Pittsburgh,

Carbon electrode used for cutting or heavy current welding
Metal electrode builds up or fills cavities when welding
Light portions show welded tube ends in locomotive
BENEATH the C & O locomotive illustrated above, which has welded seams and flue sheets, is shown a partly completed locomotive flue sheet. The light portions show flue ends which have been welded by a G-E arc welding outfit, one type of which, used by the American Locomotive Company, is shown at the bottom of this page.
This welder does its own chipping, so work can go on when your chippers are busy elsewhere. The control of heat and building of metal possible with this welder prevents distortion, uneven crystallization and cavities.
A G-E Arc Welder will repair worn or broken parts while they are in place.
Our nearest office will be pleased to give you additional information.
General Electric Company
General Office: Schenectady, N. Y.
District Offices in:
Boston, Mass. New York, N. Y. Philadelphia, Pa. Atlanta, Ga. Cincinnati, Ohio

Cleveland, San Francisco, St. Louis, Atlanta. Minneapolis, Detroit, U. S. A.
Sizes—⅜" to 3" in pitch, widths to suit powers.
Capacities—¼ hp. to 5,000 hp.
Morse "Rocker-Joint" (rolling friction principle) silent type chains exclusively, for the transmission of power for any purpose.
Licensees for Europe: Westinghouse Brake Co., Ltd., 32 York Rd., Kings Cross, London, N.
Whitney Mfg. Co., The, Hartford, Conn., U. S. A.
Cable Address: "Whitney, Hartford."
Roller—All American sizes. Block, 1" pitch, ⅛", 3/16", ¼", 5/16", ⅜" wide. Silent types, ⅜", ½", ⅝", ¾", 1" pitch, in variety of sizes.
See advertisement and send for catalogs containing useful data and information for engineers and designers.

Checks, Time and Pay
Matthews & Co., Jas. H., Pittsburgh, Penn.

Chemists
Souther Engineering Corp., Hy., Hartford, Conn.

Chip Handling Systems
American Blower Co., 1400 Russell St., Detroit.

Chucking Machines, Automatic
Bullard Machine Co., Bridgeport, Conn.
New Britain Machine Co., New Britain, Conn. 2008 W. Grand Blvd., Detroit; 949 Otis Bldg., Chicago; Cleveland.
"New Britain" Multiple-Spindle Automatics, single- and double-head types; single-head, four and five spindles, five sizes; double-head, six spindles, two sizes. For chucking castings, forgings and second-operation bar work. Performs all operations simultaneously and automatically, a finished piece being removed and a rough blank inserted at each indexing, the entire series of operations being completed in the time of the longest single operation.
Agents: Coats Machine Tool Co., Ltd., Caxton House, London, Glasgow and Newcastle-on-Tyne; Alfred H. Schutte, Cologne and Berlin; Donauwerk Ernest Krause & Co., Wien, Prague and Budapest.
Potter & Johnston, Pawtucket, R. I.
"P. J. Manufacturing Automatics." 4 sizes, 5A, 6A, 7A, 8A. Range of work varies from about 2½ diam. to 40" diam.
Warner & Swasey Co., The, Cleveland, Ohio.

Chucking Machines (See Lathes, Horizontal Turret)

Chucks, Centering
Cushman Chuck Co., The, Hartford, Conn. New York, San Francisco.
One size. Used on bench for centering short pieces from ¼" to 1½" diameter.

Chucks, Drill and Tap
Almond, T. R., 6 Maple Ave., Ashburnham, Mass.
Automatic Drill Chuck Corp'n, Majestic Bldg., Detroit, Mich.
Sizes No. 6, ⅛ in. to ⅜ in.; No. 8, 3/16 in. to ½ in. No key, collets, etc. Self-centering.
Bicknell-Thomas Co., Greenfield, Mass.
Celfor Tool Co., Buchanan, Mich.
Cleveland Twist Drill Co., Cleveland, Ohio.
Cushman Chuck Co., The, Hartford, Conn. New York, San Francisco.
Six sizes and 2 styles holding from 0 to 1" diameter drills, rods, etc. 3-jaw and 4-jaw type.
Detroit Twist Drill Co., 644 Fort St., Detroit.
Greenfield Tap & Die Corp., Greenfield, Mass.
Gronkvist Drill Chuck Co., 18 Morris St., Jersey City, N. J.
"Gronkvist" automatic 5, "Kupke" keyless 3.

Dies, Threading-Opening
Eastern Machine Screw Corp., New Haven, Conn.
Errington, F. A., 39 Cortlandt St., New York City.
Geometric Tool Co., New Haven, Conn. 545 W. Washington Blvd., Chicago, Ill. Cable: Metric.
For all classes of external screw threads of any diameter, length and form.
Greenfield Tap & Die Corp., Greenfield, Mass.
Ideal Tool & Mfg. Co., Beaver Falls, Pa. Boston, H. B. Eaton & Co. Cable: Idealdico, New York.
Leon Chapius, 26 Bd. Magenta, Paris.
Sizes ¼", ½", ¾", 1", 1¼", 2", for accurate fine and heavy thread cutting.
Jones & Lamson Machine Co., Springfield, Vt., U. S. A. Cable: Turret. Branch: Jones & Lamson Mach. Co., 97 Queen Victoria St., London, E. C.
Sizes: Nos. 1, 3, 4, 6 and 9 dies. Capacities: $\frac{9}{16}$", 1¼", 1½", 2" and 3" respectively.
An automatic opening die for use on turret lathes, automatic screw machines, engine lathes, drill presses, etc. Has wide range. Fine threads can be cut with large dies without stripping. Chasers have special lead control feature, giving accurate pitch.
Foreign Agents: Germany, Switzerland, Austria-Hungary, M. Koyeman, Charlottenstrasse 11, Dusseldorf, Germany; France, Spain, Belgium, F. Auberty & Co., 91 Rue de Maubeuge, Paris. Domestic Agents: E. A. Kinsey Co., Cincinnati, O.; E. A. Kinsey Co., Indianapolis, Ind.; Boyer-Campbell Co., Detroit, Mich.; E. L. Essley Machinery Co., Chicago, Ill.; Robinson, Cary & Sands Co., St. Paul, Minn.; Carey Mchy. & Supply Co., Baltimore, Md.; W. M. Pattison Supply Co., Cleveland, O.; Barwood-Richards Machy. Co., The Bourse, Philadelphia, Penn.
Landis Machine Co., Waynesboro, Penn.
Rotary die heads ¼" to 4". Automatic screw cutting ½", 1¼". Solid adjustable ½", 1".
Using the Landis chasers, insuring unchanged cutting contour and long life.
Murchey Mach. & Tool Co., 64 Porter St., Detroit.
National Acme Mfg. Co., Cleveland, Ohio.
National Machinery Co., Tiffin, Ohio.
Warner & Swasey Co., Cleveland, Ohio.
Wells Bros. Co., Greenfield, Mass.

Disinfectants
Houghton & Co., E. F., 240 W. Somerset St., Philadelphia, Penn.

Dogs, Lathe and Milling Machines
Hammacher, Schlemmer & Co., 13th St. and 4th Ave., New York City.
Page-Storms Drop Forge Co., Chicopee, Mass.
Union Caliper Co., Orange, Mass.
Williams Co., J. H., 35 Richards St., Brooklyn.

Drafting Tables
Almorth, G. A., 968 Grand Ave., New Haven, Conn.
Can be readily assembled to any board and is easily knocked down. Shipping weight for export, 85 lb. Frame complete for 31-inch leg room, $13.25.

Dressers, Grinding Wheel
American Emery Wheel Works, Providence, R. I.
Crafts, Arthur A., 125 Summer St., Boston, Mass.
Desmond-Stephan Mfg. Co., Urbana, Ohio.
"Diamo-Carbo" for tool grinding wheels, "Huntington & Sherman" for coarse wheels.
Diamond Saw & Stamping Wks., Buffalo, N. Y.
Trade-mark: "Sterling."
Dickinson, Thomas L., 64 Nassau St., N. Y. City
Francis & Co., 50 State St., Hartford, Conn.
Heald Machine Co., 10 New Bond St., Worcester, Mass.
Standard Tool Co., Cleveland, Ohio.
Vitrified Wheel Co., Westfield, Mass.

Drill Holders
Armstrong Bros. Tool Co., 315 N. Francisco Ave., Chicago, Ill.
Union Caliper Co., Orange, Mass.

Drill Speeders
Graham Mfg. Co., Providence, R. I.

Drilling Machine Heads
Baush Machine Tool Co., 604 Wason Ave., Springfield, Mass., U. S. A.
Adjustable multiple spindle portable drilling machine. Heads for use on all makes of drilling machines.
Hoefer Mfg. Co., Freeport, Ill.
Langelier Mfg. Co., Providence, R. I.
Nelson-Blanck Mfg. Co., Clay and Dubois St., Detroit, Mich.
Five sizes; capacities No. 0 to 1⅛" drill; weight 10 to 68 lb. Price $50 to $85.
Clamps rigidly to machine, quick adjustment.
Newman Manufacturing Co., 717 Sycamore St., Cincinnati, Ohio.
Newman quick-action four-in-one changeable drill head, carries four tools and requires but a moment to switch from one tool to another.

Drilling Machines, Automatic
Baker Bros., Toledo, Ohio.
Baush Machine Tool Co., 604 Wason Ave., Springfield, Mass., U. S. A.
Multiple head station type drilling machines for drilling, counterboring, reaming and spot facing. All tools regardless of size run at proper speed and feed.
Langelier Mfg. Co., Providence, R. I.
National Automatic Tool Co., 7th and South N St., Richmond, Ind. Cable: Natco, Richmond.
Five sizes, 2 to 200 spindles, each spindle with or without independent changes of drill speeds.

Drilling Machines, Bench
Ames Co., B. C., Waltham, Mass
Barnes Co., W. F. & John, 1995 Ruby St., Rockford, Ill.

Have You Thought of Milling Those Threads

Are you familiar with the saving in time, the increase in production in the use of the Archdale Type Thread Milling Machine on work within its range?

Especially adaptable in cutting short threads, this machine uses a milling cutter of practically the same width as the length of thread to be cut, and finishes the complete thread *in one revolution of the work.*

Let us make time estimate on some of your threading. Write for the descriptive bulletin.

Symington Co., The T. H., Rochester, N.Y., U.S.A.

Drilling Machines, Horizontal (See Boring, Drilling and Milling Machines, Horizontal)

Drilling Machines, Multiple Spindle
Baush Machine Tool Co., 604 Wason Ave., Springfield, Mass., U. S. A. Cable Address: "Baush."
Complete line of multiple spindle drilling machines, both vertical and horizontal. Also special multiple drilling machines built to order for any work.
Langelier Mfg. Co., Providence, R. I.
National Automatic Tool Co., 7th and South N St., Richmond, Ind.
Ten sizes of vertical type, ranges from 8" round head with 8 spindles to 20x48" rectangular head with 72 spindles, head feed down or table feed up, with or without power feed to head or table. Independent change of speed in head to each spindle to suit the size of holes being drilled, with neutral positions for all spindles not in use. Machines may be equipped with automatic tapping attachments, lubricating system for work, motor drive, adjustable tables, or box tables; also a complete line of 2-, 3-, 4- and 5-way horizontal and vertical type machines with fixed or adjustable spindles.
Newton Machine Tool Works, 23rd and Vine St., Philadelphia, Penn.
Pratt & Whitney Co., Hartford, Conn.
Reed-Prentice Co., Worcester, Mass.
Sellers & Co., Inc., Wm., Philadelphia, Penn.
Stecher Co., The Charles, 1576 Crossing St., Chicago.

Drilling Machines, Pneumatic
Independent Pneumatic Tool Co., Thor Bldg., Chicago, Ill.
Ingersoll-Rand Co., 11 Broadway, New York.
"Little David," all sizes, types and gearing combinations for drilling, reaming, tapping, flue rolling, stud seating, etc.

Drilling Machines, Radial
American Tool Works Co., The, Cincinnati, U. S. A. Cable: "Lathe, Cincinnati."
Sizes—Plain, 2, 2½, 3, 3½, 4, 5, 6, 7-ft. arms; full universal, 4, 5, 6, 7 ft. Sensitive radial 3 ft. ball bearing throughout. Sizes 2 to 3½ ft. inclusive equipped with back gears; 4 to 7 inclusive with triple gears. All full universal are triple geared. Four different types of drives for all sizes: Cone drive, geared speed box for belt and motor drive and direct connected variable speed motor drive without speed box.
See our advertisement on pages 14 and 15.
Baush Machine Tool Co., 604 Wason Ave., Springfield, Mass.
Cincinnati Bickford Tool Co., The, Oakley, Cincinnati, Ohio. Cable: Augustus, Cincinnati.
Regular plain type: 6 sizes, ranging from 2½' to 6'. Universal type: 3 sizes, ranging from 4' to 6'. High speed, high power type, with a 5, 6, 7 or 8' arm and base.
Plain and universal radials furnished with a cone, speed box, variable speed motor or motor and speed box drive. The high-speed radial with a speed box, variable speed motor or constant speed motor and speed box drive. All types of plain, universal and high-speed radials can be furnished with cutting lubricant equipment. Plain and high-speed types with air column binder.
Dreses Machine Tool Co., 227-241 W. McMicken Ave., Cincinnati, O. Cable Address: Dreses.
Sizes—Plain 2½ to 7 ft. Half and full universal 4 to 7 ft.
Cone, speed variator (single pulley) and motor drive.
Fosdick Machine Tool Co., Cincinnati, Ohio.
Sizes: High speed manufacturing, 2', 2½', 3'; heavy duty, 3', 3½', 4', 5', 6'. Cone pulley, gear box, constant or variable speed drives. Plain tilting or universal tables.
Carlton Mach. Tool Co., Cincinnati, Ohio.
Sizes 2½', 3', 3½', 4'.
Harrington, Son & Co., Inc., Ed., Philadelphia, Pa.
Morris Mach. Tool Co., Cincinnati, Ohio.
2½', 3' and 3½'. Cone pulley gear box, constant speed motor, with gear box and variable speed motor.
Mueller Machine Tool Co., Cincinnati, Ohio.
Niles-Bement-Pond Co., 111 Broadway, N. Y. C.
Reed-Prentice Co., Worcester, Mass.
Sellers & Co., Inc., Wm., Philadelphia, Penn.
Strong, Carlisle & Hammond Co., Cleveland, Ohio.
Almond high-speed radial drill intended for light drilling and tapping. Ball bearing throughout. Entirely self-contained. Radius of 48" up to within 12" of column. Drill can be brought over any part of work with one motion of arm. Spindle speeds from 195 up to 2,000 r.p.m.

Drilling Machines, Sensitive
Coats Mach. Tool Co., Inc., 30 Church St., N. Y. C.
Henry & Wright Mfg. Co., 760 Windsor St., Hartford, Conn.
One to 8 spindles, 300 models drilling up to 1¼". Weights, 760 lb. to 5,000 lb.
Agents: Hill, Clarke & Co., Boston, New York and Chicago; Chas. A. Strelinger Co., Detroit; W. E. Shipley Mchry. Co., Philadelphia; Brandes Machy. Co., Cleveland, Ohio.

New York Chicago Indianapolis Detroit

Simonds Mfg. Co., Fitchburg, Mass. Established 1832. 17th St. and Western Ave., Chicago, Ill.; 90 West Broadway, N. Y. C.
Makers of saws, machine knives, files, sheet and bar steel.

Filing Machines
Ames Co., B. C., Waltham, Mass.
Anderson Die Machine Co., Bridgeport, Conn.
Cochrane-Bly Co., Rochester, N. Y.
Detrick & Harvey Mach. Co., Baltimore, Md.
Oliver Instrument Co., 1168 Cass Ave., Detroit, Mich.
Rearwin, W. D., Mill Ave., N. W., Grand Rapids, Mich. Length of stroke adjustable from 0 to 7". Irregular shape files can be used in this machine Weight 375 lb.

Filler, Iron (See Cements, Iron)

Fittings, Hydraulic
Elmes, Chas. F., 1001 Fulton St., Chicago, Ill.
Watson-Stillman Co., 42 Church St., N. Y. City.

Flexible Shafts
Errington, F. A., 39 Cortlandt St., N. Y. City.
Gem Mfg. Co., 3257 Spruce St., Pittsburgh, Pa. ½ to 1⅝" core.
Stow Mfg. Co., Binghamton, N. Y. 85 Queen Victoria St., London, E. C., England.

Fluxes
Basic Mineral Co., North Side, Pittsburgh, Penn. Foreign Agents: R. Martens & Co., Inc., 24 State St., New York City.

Forging Dies
Keller Mechanical Engraving Co., Brooklyn, N. Y. Agents: England, France, Italy, Alfred Herbert, Ltd.

Forging Machinery
Acme Machinery Co., Cleveland, Ohio. Cable Address: Acme, Cleveland.
Billings & Spencer Co., Hartford, Conn.
National Machinery Co., Tiffin, Ohio.

Forgings, Drop
Billings & Spencer Co., Hartford, Conn.
Bliss & Co., E. W., 1 Adams St., Brooklyn, N. Y.
Camden Forge Co., Mt. Ephraim Ave., Camden, N. J.
Page-Storms Drop Forge Co., Chicopee, Mass.
Whitman & Barnes Mfg. Co., Akron, Ohio.
Williams Co., J. H., 35 Richards St., Brooklyn.

Forgings, Hammer
Billings & Spencer Co., Hartford, Conn.
Camden Forge Co., Mt. Ephraim Ave., Camden, N. J.
Smooth forged, rough turned or finished complete.
Halcomb Steel Co., Syracuse, N. Y.
Hobson, Houghton & Co., 83 Beekman St., N. Y.
Page-Storms Drop Forge Co., Chicopee, Mass.
Williams Co., J. H., 35 Richards St., Brooklyn.

Foundry Supplies
Berger Mfg. Co., Canton, Ohio.
Dixon Crucible Co., Joseph, Jersey City, N. J.
Paxson Co., J. W., 1021 Delaware Ave., Phila.
Whiting Foundry Equipment Co., Harvey, Ill.

Foundry Systems
McLain, David, 909 Goldsmith Blg., Milwaukee, Wis.

Fountains, Drinking
Manufacturing Equipment & Engineering Co., 209 Washington St., Boston, Mass.

Furnaces, Heat Treating, Oil and Gas
American Gas Furnace Co., 24 John St., N. Y. C.

Strong Carlisle Hammond Co., Cleveland, Ohio.

Furnaces and Ovens, Electric
Brown Instrument Co., Philadelphia, Penn.
General Electric Co., Schenectady, N. Y.

Furniture, Machine Shop
Berger Mfg. Co., Canton, Ohio. Boston, New York, Philadelphia, Chicago, St. Louis, Minneapolis, San Francisco.
Berger's sectional steel bins and shelving. Types: Closed, open and rack. Combine strength, flexibility and economy with convenience and safety. They afford 25% more storage capacity than wood, will hold heavy loads and are practically indestructible. Fire-retardant and cannot warp, split or rot. Factory tote boxes—strong, light and durable; facilitate handling of stock. See advertisement.
Garwood Bronze and Iron Wks., Garwood, N. J.
Manufacturing Equipment & Engineering Co., 209 Washington St., Boston, Mass.
New Britain Machine Co., New Britain, Conn.
Pressed steel bench legs; frictionless bench drawers; countershaft standards for bench lathes; seat supports for locker rooms; work stands and vise stands, portable and stationary; storage racks for bar stock; tool storage racks; blacksmiths' tool rack and work stands; pantop racks; skeleton-frame racks; lathe tool-racks with drawer; revolving screw racks; stock rack, guide and support for turret lathe or screw machine; shop shelving; pivot base racks; adjustable scraping tables; molders' ramming stands; adjustable stools, wood seats; rungs for permanent ladders; stanchions for guard rails and machine guards; nesting and stacking tote-boxes, electrically welded.
Western Tool & Mfg. Co., Springfield, Ohio.

Gages, Dial
Ames Co., B. C., Waltham, Mass.
Brown & Sharpe Mfg. Co., Providence, R. I.
Randall & Stickney, Waltham, Mass.
Starrett Co., L. S., Athol, Mass.

Gages, Measuring
Becker Milling Mach. Co., Hyde Park, Mass.
Bicknell-Thomas Co., Greenfield, Mass.
To order for all purposes; also scred thread testing gages.
Brown & Sharpe Mfg. Co., Providence, R. I.
Carroll Engineering Co., The, Dayton, Ohio.
Cleveland Twist Drill Co., Cleveland, Ohio.
Adjustable limit and snap, adjustable for size and wear.
Grayson Tool & Mfg. Co., Indianapolis, Ind.
Greenfield Tap & Die Corp., Greenfield, Mass.
Gronkvist Drill Chuck Co., 18 Morris St., Jersey City, N. J.
"Johansson" combination standard gages, furnished in systems to give all sizes in .00005", .0001", .0005", .001", 64ths, 32nds, 16ths and mm. Accuracy .00001". Prices according to combination.
"Johansson" adjustable limit snap gages, adjustable for wear, different sizes and changing limits. Made with insulated grip. Capacity of smallest size is 0-¼"; capacity of largest size 11"-12".
"Johansson" tolerance plug gages, all sizes up to 8". Reversible, interchangeable measuring members. Light weight.
Harris Eng. Co., The, H. E., Bridgeport, Conn.
Hartford Special Mchy. Co., The, 287 Homestead Ave., Hartford, Conn.
Bench taper gage, with a wide range for tool-room and manufacturing requirements. Adjustable to measure any size taper from nothing up to a No. 14 Browne & Sharpe taper. More accurate than a ring gage. In operation it sets on the bench on its adjustable stand, enabling the operator to set the gage at just the correct height for his eyes, so he may look through the gage toward the light. Send for circular.
Krasberg Mfg. Co., 410-420 Orleans St., Chicago, Ill.

Gear Cutting Machines
Adams Co., 1902 Bridge Ave., Dubuque, Iowa.
American Die & Tool Co., Reading, Penn.
Barber-Colman Co., Rockford, Ill.
Becker Milling Machine Co., Hyde Park, Mass.
Bilgram Machine Works, 1233 Spring Garden St., Philadelphia, Penn.
Brown & Sharpe Mfg. Co., Providence, R. I.
For spur and bevel gears. 3 sizes. For spur gears only. 5 sizes.
Descriptive circular on request.
Cincinnati Gear Cutting Machine Co., The, Cincinnati, Ohio, U. S. A. Cable: "Tools."
Full automatic spur gear cutters; capacities 26"x10" to 84"x24".
Fellows Gear Shaper Co., The, Springfield, Vt.
No. 6—capacity for spur gears 35" pitch diameter, 5" face, 4 diametrical pitch; for internal gears 26" pitch diameter, 3" face, 4 pitch. No. 65—capacity 35" pitch diameter, 5" face, 6 diametral pitch. Weight of No. 6, 3,855 lb.; weight of No. 65, 4,116 lb. No. 6 machine cuts spurs and internals only and uses a cutter of the generating type. No. 65 is a machine for helicals only and uses a cutter of the generating type.
Flather Mfg. Co., E. J., Nashua, N. H.
Garvin Mach. Co., Spring and Varick St., N. Y. C.
Gleason Works, Rochester, N. Y.
Gould & Eberhardt, Newark, N. J.
Disc cutter type for spur gears. Horizontal cutting type. Sizes—36", 60", 72". Vertical cutting type. Sizes—36", 60", 120".
For spur and bevel gears. Horizontal cutting type 62" and 74". Vertical cutting type 24" and 48".
Hobbing type for spur, helical and worm gears. Sizes: 12", 18", 36", 72".
Multiple spindle type for roughing out spur and bevel gears. 24" for cutting 2 gears at one time up to 11" dia. or 3 gears at one time up to 5½" dia. 48" for cutting 2 gears at one time up to 18" dia. or 3 gears at one time up to 9" dia.

Lees-Bradner

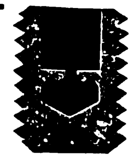
THREAD MILLING MACHINES

For

ALL PURPOSES

The Lees - Bradner Company
Cleveland, Ohio, U. S. A.

Some Solid "dope" on Set Screws



There's a big difference in Safety Set Screws both outside and **inside.**

That is why we have cut these two apart—**to show you.** Look at the finish of the Allen Screw; perfect clean cut threads, solid point with plenty of metal to take the strain and above all the clean, cut socket.

Then look at the **broached** screw in the small cut. You can see the difference in a moment. That's because the Allen patented process makes a clean hole which a broach cannot possibly **imitate.** That's the word, and pretty poor imitation at that.

Write us for free samples and circular No. 10.

Grinding Wheels
American Emery Wheel Wks., Providence, R. I.
Corundum wheels, carbolite wheels, emery wheels. All sizes, shapes, grits, grades.
Carborundum Co., Niagara Falls, N. Y. N. Y. City, Chicago, Boston, Phila., Cleveland, Cincinnati, Pittsburgh, Milwaukee, Grand Rapids, Manchester, Eng.; Dusseldorf, Germany.
Carborundum and Aloxite grinding wheels.
Dickinson, Thomas L., 64 Nassau St., N. Y. City.
Norton Co., Worcester, Mass. New York, 151 Chambers St.; Chicago, 11 N. Jefferson St.; Niagara Falls, N. Y.; Chippewa, Ont., Can.; Bauxite, Ark.; Wesseling, Bz. Coln, Germany.
Sizes up to 6' diam. made of Alundum and Crystolon.
Safety Emery Wheel Co., Larch St., Springfield, O.
Agents: Farmer & Co., London; Adler & Eisenchitz, Milan; Allied Machinery Co. of America, Paris.
Springfield Grinding Co., Springfield, Mass., U. S. A. Address inquiries to factory, Chester, Mass., U. S. A. Cable Address: "Maxf," Springfield, U. S. A.
"Maxf" grinding wheels; vitrified, silicate or elastic wheels, made from both natural and artificial abrasives, tested and passed upon in our own laboratory before using; made in all sizes of every grade, grain and shape, for every purpose. Our expert engineers are prepared to take up your grinding problems and ascertain the best grain and grade for your particular work. See advertisement.
Sterling Grinding Wheel Co., Tiffin, Ohio.
Vitrified Wheel Co., Westfield, Mass.

Grindstones and Frames
Norton Co., Worcester, Mass.

Grooving Machine Oil
Fischer Machine Co., Philadlephia, Penn

Gun-Barrel Machinery
Pratt & Whitney Co., Hartford, Conn.
Reed-Prentice Co., Worcester, Mass.

Hammers, Belt Driven
Beaudry & Co., Inc., 141 Milk St., Boston, Mass.

Gray & Prior Mach. Co., Hartford, Conn.
Manufacturers Equipment & Engineering Co., 209 Washington St., Boston, Mass.

Key Seating Machines
Baker Bros., Toledo, Ohio.
Chattanooga Machinery Co., Chattanooga, Tenn.
Cable: Radcliffe.
For keyseats $\frac{1}{16}$" to 5" wide, 6" to 40" long. Weight, 400 lb. to 5,000 lb.
Cuts internal keyways in straight and taper holes with no limit to outside diameter of work. Cutter bar is self-contained with feeding mechanism and self-relieving cutter. Cutters are placed in and removed from bar without use of wrenches or tools. Work centered by bushings fitting to bore. Belt or motor driven.
Lapointe Machine Tool Co., The, Hudson, Mass.
Cable Address: "Lapointe," Hudson.
Horizontal type, 4 sizes, capacity up to 4" wide.
La Salle Machine & Tool Co., La Salle, Ill.
Mitts & Merrill, 913 Tilden St., Saginaw, Mich.
Morton Mfg. Co., Muskegon Heights, Mich.
Stationary keyway cutters, 18 to 48" stroke.
National Mach. Tool Co., Cincinnati, Ohio.
Internal portable keyseaters.
Newton Machine Tool Works, 23rd and Vine St., Philadelphia, Penn.
Niles-Bement-Pond Co., 111 Broadway, N. Y. C.

Keys, Machine
Lapointe Co., J. N., New London, Conn. Cable Address: Lapointe, New London.
Moltrup Steel Products Co., Beaver Falls, Penn.
Finished gib head and plain taper, all kinds.
Morse Twist Drill & Mach. Co., New Bedford, Mass.
Morton Mfg. Co., Muskegon Heights, Mich.
Standard Gauge Steel Co., Beaver Falls, Penn.
Whitney Mfg. Co., The, Hartford, Conn., U. S. A.
Machine keys and cutters for the Woodruff system of keying.
Williams Co., J. H., 35 Richards St., Brooklyn.

Knives, Machine
Coes Wrench Co., Worcester, Mass.

Knurl Holders
Armstrong Bros. Tool Co., 315 N. Francisco Ave., Chicago, Ill.
Graham Mfg. Co., Providence, R. I.
For turret machines only.
McCroskey Reamer Co., Meadville, Penn.
Williams Co., J. H., 35 Richards St., Brooklyn.

Lamp Brackets, Adjustable
Newman Mfg. Co., 717 Sycamore St., Cincinnati, Ohio.

Lamps
Benjamin Elec. Mfg. Co., 120 Sangamon St., Chicago, Ill.
General Electric Co., Schenectady, N. Y.
Westinghouse Elec. & Mfg. Co., Pittsburgh, Penn.

Lathe Attachments
Dalton Mach. Co., Inc., 1911 Park Ave., N. Y. C.

Lathe Pans, Portable
New Britain Machine Co., New Britain, Conn.
Cast-iron, double and single types, all sizes.

Lathe Tools
Armstrong Bros. Tool Co., 315 N. Francisco Ave., Chicago, Ill.
Chard Lathe Co., Newcastle, Ind., U. S. A. Cable Address: "Chard, Newcastle."
Pratt & Whitney Co., Hartford, Conn.
Union Caliper Co., Orange, Mass.
Western Tool & Mfg. Co., Springfield, Ohio.
Williams Co., J. H., 35 Richards St., Brooklyn.

Lathes, Automatic and Semi-Automatic
Coats Mach. Tool Co., Inc., 30 Church St., N. Y. C.
Greaves, Klusman Tool Co., Cincinnati, Ohio.
Jones & Lamson Machine Co., Springfield, Vt., U. S. A. Cable Address: Turret. Branch: Jones & Lamson Machine Co., 97 Queen Victoria St., London, E. C., England. Cable: Turretorum.
Sizes: 14" Fay automatic lathe; swings 14" over bar, 11" over carriage, takes 17" between centers; automatic feed 10".
For finishing work held on centers or on centered arbors; especially for second operation work carried on arbors. Universal cam adjustments and tool holders permit the use of ordinary forged lathe tools for complicated operations. Machine is entirely automatic, except for changing work.

Agents: Germany, Switzerland, Austria-Hungary, M. Koyemann, Charlottenstrasse 112, Dusseldorf, Germany; France, Spain and Belgium, F. Auberty & Co., 91 Rue de Maubeuge, Paris.
National-Acme Mfg. Co., Windsor, Vt., U. S. A. Cable: "Machine," Windsor, Vt.
Gridley multiple-spindle automatics. 3 sizes: ¾"x4½", 1¼"x5½" and 2¼"x7". Hold four bars of stock in the spindle-carrying cylinder, which revolves step by step, bringing each spindle with its bar successuvely into alignment with each tool. The tool slide upon which the tools are mounted and whose axis is concentric with that of the cylinder does not revolve, but through its automatically controlled longitudinal movement it feeds the tools to the work.
Potter & Johnston Machine Co., Pawtucket, R. I. "P. J. Manufacturing Automatics." 4 sizes, 5A, 6A, 7A, 8A. Range of work varies from about 2½" diam. to 40" diam.
Steinle Turret Machine Co., Madison, Wis. Cable Address: Steinle, Madison.
Full-swing side carriage turret lathes and special attachments. Sizes 24-in. Steinle turret lathe; swings 24 in. over V's, 21 in. over carriage, traverse of turret 56 in. Both carriages are screw cutting, with reversible feeds in aprons, moved back and forth automatically. Lathe requires only one belt direct from line shaft. Belt-driven machine can be changed to electric drive at any time. Manufacture the following attachments to be used on Steinle lathes: High-speed drilling attachment; pistonring cutting, boring and cutting-off attachment; cone pulley turning attachment, etc. Designed to increase production and extend life of machine.

Lathes, Bench

Ames Co., B. C., Waltham, Mass.
Blount Co., J. G., Woodland St., Everett, Mass.
Dalton Mach. Co., Inc., 1911 Park Ave., N. Y. C.
Oliver Mfg. Co., W. W., Buffalo, N. Y. Cable: Oliver, Buffalo.
Pratt & Whitney Co., Hartford, Conn.
Rivett Lathe & Grinder Co., Brighton, Boston, Mass. Cable: Edrivett.
Five sizes. Capacities: 7" to 8½" swing, 18" to 22" between centers.
No. 3½, No. 4 and No. 5 plain bench lathes; No. 6, chasing bar lathe; No. 8, back geared screw-cutting lathe.
See our advertisement on inside of back cover.
Seneca Falls Mfg. Co., 687 Water St., Seneca Falls, N. Y.
9" and 11" "Star" screw-cutting bench lathes, 10" speed and woodturning bench lathes.
Stark Tool Co., Watlham, Mass.
Waltham Mach. Works, High St., Waltham, Mass.
Wells & Son Co., F. E., Greenfield, Mass.

Lathes, Boring

Davenport Locomotive Wks., Davenport, Iowa
Detrick & Harvey Machine Co., Baltimore, Md. Cable: Detharvey.
For boring light and heavy guns. 3" to 6". Any length of bed.
Niles-Bement-Pond Co., 111 Broadway, N. Y. C.
Potter & Johnston Machine Co., Pawtucket, R. I.
Root & Vandervoort Eng'g. Co., East Moline, Ill.

Lathes, Chucking (See Lathes, Horizontal Turret)

Lathes, Engine

Acme Machine Tool Co., Buck St., Cincinnati, O. Cable Address: Acme.
American Tool Works Co., The, Cincinnati, U. S. A. Cable: "Lathe, Cincinnati."
Sizes 14, 16, 18, 20, 24, 27, 30, 36, 42".
Five different types of headstocks: Single back geared, double back geared, triple geared, patented geared head for belt and for motor drive. Quick change gear type and patented top Vee bed.
See our advertisement on pages 14 and 15.
Bailey, R. W., 122 S. Michigan Ave., Chicago, Ill.
Barnes Co., W. F. & John, 1995 Ruby St., Rockford, Ill.

Detroit Precision Tool Co., Detroit, Mich.
Douglas, W. & B., Middletown, Conn.
"Connecticut" high-duty lathes for turning and boring high carbon steel forgings and other materials at fast speeds. Heavy, rigid and powerful. See advertisement and send for catalog.
Dreses Machine Tool Co., Cincinnati, Ohio.
Dunlap Mfg. Co., Columbus, Ohio.
21" high duty, heavy construction, for shell machining; 4 speeds, 6" double belt drive, back gear ratio 11 to 1. Send for Circular "A."
Earle Gear & Machine Co., 101 East Wyoming Ave., Philadelphia, Penn.
Fitchburg Machine Works, Fitchburg Mass.
Flather & Co., Inc., Nashua, N. H.
Greaves, Klusman Tool Co., Cincinnati, Ohio.
Harrington, Son & Co., Inc., Ed., Philadelphia, Pa.
Hendey Machine Co., The, Torrington, Conn. Cable: Hendey, Torrington. Branches: Singer Bldg., New York City; Oliver Bldg., Boston; Sharples Bldg., Chicago.
Sizes made—12, 14, 16, 18, 20, 24" swing; lengths of bed from 4' to 24' according to swing. Quick change geared. Have taper bearings with ring oiling system for main spindle, and gearing is so arranged that extra gears can be added in train without limit for cutting extra threads if wanted.
Agents: Sherritt & Stoer, Philadelphia; Syracuse Supply Co., Syracuse and Buffalo; W. M. Pattison Supply Co., Cleveland, Dayton, Detroit; Colcord-Wright Mchy. & Supply Co., St. Louis; Pacific Tool & Supply Co., San Francisco; A. R. Williams Mchy. Co., Toronto; Williams & Wilson, Montreal; Chas. Churchill & Co., London; D. Drury & Co., Johannesburg.
Hill, Clarke & Co., Inc., 156 Oliver, Boston, Mass.
Himoff Mach. Co., Inc., 128 Mott St., N. Y. C.
Houston, Stanwood & Gamble Co., Cincinnati, O.
30-in. swing, heavy pattern, high powered lathe, with special purpose headstock, all-geared and designed to transmit 20 hp.
Jenckes Knitting Mach. Co., Pawtucket, R. I.
Turns up to 5 pieces simultaneously according to length.
LeBlond Machine Tool Co., R. K., Cincinnati, O.
Lodge & Shipley Machine Tool Co., Cincinnati, O. Cable: Drill.
Sizes 14 to 48" swing, any length bed. Quick change gear, screw-cutting engine lathes, cone head. Also with single pulley, all geared selective head.
Monarch Machine Tool Co., Sidney, Ohio.
14", 16", 18" and 20" swing.
Morris Mach. Tool Co., Cincinnati, Ohio.
16" quick change and semi-quick change; 16" double and single back gear; 18" double and single back gear.
Mueller Machine Tool Co., Cincinnati, Ohio.
National-Acme Mfg. Co., Cleveland, Ohio.
Niles-Bement-Pond Co., 111 Broadway, N. Y. C.
Pittsburgh Machine Tool Co., Braddock, Penn.

Prentiss Tool & Supply Co., Singer Bldg., N. Y. C.
Reed-Prentice Co., Worcester, Mass.
Sebastian Lathe Co., 117 Culvert St., Cincinnati, O.
Seneca Falls Mfg. Co., The, 687 Water St., Seneca Falls, N. Y.
9", 11" and 13" "Star" screw cutting engine lathes, and 12", 14" and 16" Seneca Falls quick change engine lathes with a large line of attachments.
Springfield Machine Tool Co., The, Springfield, Ohio. Cable: Montanus.
Sizes 14, 16, 18, 20, 24, 30, 36-in. swing. Capacities—Any length beds and all special equipment. Three sizes Fox monitor lathes, 15, 18 and 20" swing. Single pulley all geared head lathes, 14, 16, 18" swing.
Strong Carlisle Hammond Co., Cleveland, Ohio.
Symington Co., The T. H., Rochester, N.Y., U.S.A.
Toomey, Inc., Frank, Philadelphia, Penn.
Walcott Lathe Co., Calhoun St., Jackson, Mich. Made in 14-, 18-, 20- and 25-in. sizes.
Young, Corley & Dolan, Inc., 149 Broadway, N. Y.

Lathes, Extension and Gap

American Tool Works Co., Cincinnati, Ohio.
Barnes Drill Co., 830 Chestnut St., Rockford, Ill. 14-24" and 22-36" sizes.
Harrington, Son & Co., Inc., Ed., Philadelphia, Pa.
Niles-Bement-Pond Co., 111 Broadway, N. Y. C.

Lathes, Foot Power

Barnes Co., W. F. & John, 1995 Ruby St., Rockford, Ill.
Reed-Prentice Co., Worcester, Mass.
Seneca Falls Mfg. Co., 687 Water St., Seneca Falls, N. Y.
9" and 11" Star foot power screw-cutting engine lathes, 10" foot power speed and woodturning lathes.
Wells & Son Co., F. E., Greenfield, Mass.

Lathes, Horizontal Turret

Acme Machine Tool Co., Buck St., Cincinnati, Ohio. Cable Address: Acme.
Flat turret type (two sizes), bar work 2¼" and 3¼" diameter. Chucking work 12" and 16" diameter. High turret type (four sizes), 14" to 20" swing.
American Tool Wks. Co., Cincinnati, Ohio.
Blount Co., J. G., Woodland St., Everett, Mass.
Bradford Mach. Tool Co., Cincinnati, Ohio.
Champion Tool Wks. Co., 2424 Spring Grove Ave., Cincinnati, Ohio.
Cleveland Crane & Engineering Co., Wickliffe, O.
Davis Machine Tool Co., Inc., 311 St. Paul St., Rochester, N. Y.
Dreses Machine Tool Co., 227-241 W. McMicken Ave., Cincinnati, O. Cable: Dreses, Cincinnati. Sizes—13" to 20" swing.
With plain and universal slides. Plain and friction back geared. Power feed Belt and motor driven.
Himoff Mach. Co., Inc., 128 Mott St., N. Y. C.
Jones & Lamson Machine Co., Springfield, Vt., U. S. A. Cable: Turret. Branch: Jones & Lamson Machine Co., 97 Queen Victoria St., London, E. C., England. Cable: Turretorum.
Sizes — 2¼", 3" and double spindle; 12" and 14" swing respectively for single spindle, and 10" for double spindle, or 17" when used as a single spindle machine.
Has flat turret and cross sliding head, universal tool holders and simple forged tools. Complicated work set up quickly without special tooling; suitable for small lots or continuous manufacturing. Double spindle machine similar in principle and equipment, but does two pieces of work at the same time, for high production work, 2¼ and 3" machines also sold with bar outfits.
Agents: Germany, Switzerland, Austria-Hungary, M. Koyemann, Charlottenstrasse 112, Dusseldorf, Germany; France, Spain and Belgium, F. Auberty & Co., 91 Rue de Maubeuge, Paris.

Piston-Ring Machines
Heald Machine Co., 10 New Bond St., Worcester, Mass.
National-Acme Mfg. Co., Windsor, Vt., U. S. A. Cable: "Machine," Windsor, Vt.
Gridley piston and ring machines are semi-automatic. Turn the outsides of the rings eccentric at the same time that the insides of the rings are being bored concentric. Make pistons and rings up to 6" in diameter.
Potter & Johnston Machine Co., Pawtucket, R. I. Capacity pistons 3" up to 8½" diameter up to 12" long. Piston rings 3" up to 8½" diam., any width required. Send for circular 24.
Pratt & Whitney Co., Hartford, Conn.
Walker Co., O. S., Worcester, Mass.

Planer, Parallels
Taft-Peirce Mfg. Co., Woonsocket, R. I.
Walker Co., O. S., Worcester, Mass.

Planing Machines
American Tool Works Co., The, Cincinnati, U. S. A. Cable: "Lathe, Cincinnati."
Sizes 24, 26, 28, 30, 36, 42, 48, 60" between housings. Built with 1, 2, 3 or 4 heads and 6 different types of drive: Single speed, belt or motor drive; double speed through 2-speed countershaft; 4 speed, through patented cone speed variator for belt or motor drive and with variable speed motor drive with reversing motor equipment. All sizes are equipped aluminum tight pulleys.
See our advertisement on pages 14 and 15.
Betts Machine Co., Wilmington, Del.
Cincinnati Planer Co., The, Cincinnati, Ohio. Cable: Planer.
22" to 96" planers, frog and switch, shoe and wedge and cylinder planers.
Patent "Tu-Speed" type, quick reverse aluminum pulleys, all gearing inside beds, safety locking device, simplex feed gears, patent power elevating device, patent tumbler and dogs, ball bearings on feed screws.
Agents: Prentiss Tool & Supply Co., New York; W. E. Shipley Mchy. Co., Philadelphia; Motch & Merryweather Co., Cleveland, Ohio; Marshall & Huschart Co., Chicago.
Cleveland Planer Works, 3148 Superior Ave., Cleveland, Ohio. Open side, frog and switch. Seven sizes. Capacities 26" to 72", any length.
Coats Mach. Tool Co., Inc., 30 Church St., N. Y. C.
Detrick & Harvey Machine Co., Baltimore, Md. Cable: Detharvey.
Open side. 30" to 96". For wide work beyond limits of double housing planes. Spiral gear drive. Open side convertible. 42" to 96". For double housing planer work. Addition of outer housing turns open side planer into double housing planer. Spiral pinion drive. Double housing—42" to 120". For uninterrupted double housing planer work. Spur gear drive. All beds of closed box type. Motor or belt driven
Gray Co., The G. A., Cincinnati, Ohio. Cable: Address: "Gray, Cincinnati."
Thirty sizes: 22"x22" to 84"x60". Spur geared and spiral geared planers. Constant and variable speed. Belt and motor driven.
Foreign Agents: Oznosskoff Suckau & Co., Petrograd; R. S. Stokvis & Fils, Ltd., Paris; R. S. Stokvis & Zonen, Ltd., Rotterdam; Chas. GARVIN

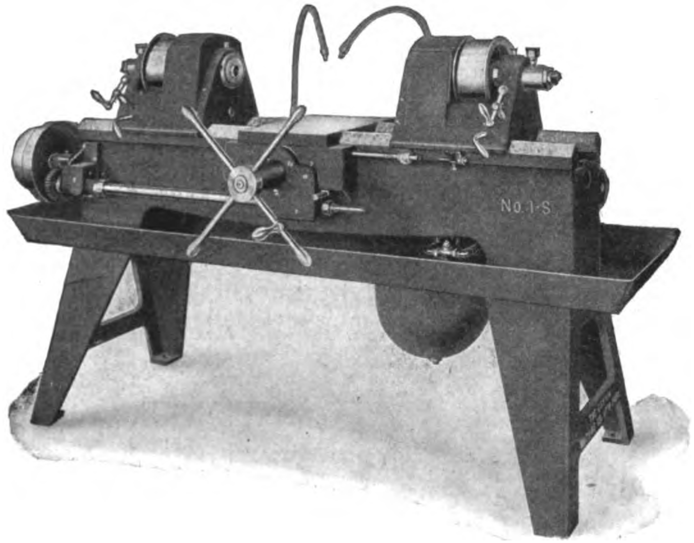
Duplex Horizontal Drills

(Screw and Rack Feed — Numerous Sizes — Double Your Output)



No. 1—S. B. G. Duplex Horizontal Drill
Screw Feed, Back Geared, 3 to 1. Use Code......Crust Clutch.

Duplex means double—two-fold—A Duplex Drill is one which works with two drills at once—Garvin Duplex Horizontal Drills will drill, counter-bore, hollow mill or turn simultaneously from opposite directions, resulting in doubling the output and work of superior quality—Machines have become very popular and we now carry a stock of them. Send us your samples or blueprints. Capacities from $\frac{1}{8}$ up to 2 inches.

Send Today for Our Complete Catalog. For Further Information, Ask Your Dealer or Write Us Direct.

They HAD to use "CRATER"

We have as a customer for "CRATER," a large Iron and Steel Company who operate a large battery of coke ovens, in conjunction with their mills.

They made their own "lubricant"

As a byproduct they obtain a coal tar, which they formerly employed for "lubricating" their gears, and which they sold to outside trade.

This cost them next to nothing.

They tried "CRATER"

One of our salesmen, with a faith in "CRATER" that knows no obstacles, induced them to accept a sample of TEXACO CRATER COMPOUND. He assisted in the application of this sample to several worn gears. In quick time they realized its value as a real lubricant, and preserver of gears.

On a cost basis

They spoke about the cost. A comparative test against their own product was inaugurated.

"CRATER" won out

This test showed that so little "CRATER" was needed to lubricate the gears properly, and that it stood up against the high radiated heat, the pressure, and the chemical vapors so well, that they could not afford to be without it. "CRATER" saved many times its cost in gear life—to say nothing of the increased service from machines by eliminating replacements and delays.

They sell the other BUT THEY USE "CRATER"

They order it in carload lots now. They use "CRATER" on all their gears, cables, and elevator chains.

It pays them.

They sell their own product to customers outside, BUT THEY USE "CRATER."

Write for the book

If you want to know a little more about this remarkable lubricant, ask for a copy of the "CRATER BOOK." It details some of the properties, performance, and uses of "CRATER," and illustrates a few of the gears on which "CRATER" is working with success. However, if you really want to see how much "CRATER" will save in your plant, arrange for a trial order. We will be glad to send you a sufficient quantity for a test, with instructions for the best way of applying it.

SAVE THE GEARS

This is all very simple.

We want to remind our readers of the fact that TEXACO CRATER COMPOUND is a straight mineral lubricant made by a Company which has a background of unlimited success in the manufacture and application of the right oil for any purpose whatever.

Write for the "CRATER BOOK."

Strong, Carlisle, Hammond Co., Cleveland, Ohio.

Shapes, Cold-Drawn Steel
Moltrup Steel Products Co., Beaver Falls, Penn.
Union Drawn Steel Co., Beaver Falls, Penn.

Shears, Hand
Armstrong-Blum Mfg. Co., 347 N. Francisco Ave., Chicago, Ill.
Oliver Mfg. Co., W. W., Buffalo, N. Y. Cable: Oliver, Buffalo.

Shears, Power
Bethlehem Steel Co., Machinery Dept., South Bethlehem, Penn.
Birdsboro Steel Fdry. & Mach. Co., Birdsboro, Pa.
Canton Fndy. & Mach. Co., Canton, Ohio.
Ferracute Machine Co., Bridgeton, N. J.
Groos Co., 16th and Owen Ave., Racine, Wis.
Long & Allstatter Co., Hamilton, Ohio.
Mitts & Merrill, 913 Tilden St., Saginaw, Mich.
Niagara Mach. & Tool Works, Buffalo, N. Y.
Royersford Fdry. & Mach. Co., Royersford, Penn.
Toledo Machine & Tool Co., Toledo, Ohio.
Union Twist Drill Co., Athol, Mass.

Shell Machinery, Special
Langelier Mfg. Co., Providence, R. I.
Root & Vandervoort Eng'g. Co., East Moline, Ill.
Symington Co., The T. H., Rochester, N.Y., U.S.A.
25 different machines designed especially for manufacturing shells and fuse sockets from 3"

to 6" in diameter. Machines are made for the single purpose of one operation and are operated with unskilled labor. Machine furnished complete with tools ready to operate.

Sheet Metal Working Machinery
Ferracute Machine Co., Bridgeton, N. J.
Niagara Mach. & Tool Works, Buffalo, N. Y.
Savage Co., Inc., W. J., Knoxville, Tenn.
For cutting sheet metal and plates in any conceivable shape without springing or buckling material. Capacity up to $\frac{3}{16}$" inclusive.
Stecher Co., The Charles, 1576 Crossing St., Chicago. Can making.
Toledo Machine & Tool Co., Toledo, Ohio.

Shelving, Steel (See Furniture, Machine Shop)

Slide Rests
Betts Machine Co., Wilmington, Del.
Reed-Prentice Co., Worcester, Mass.

Slotters, Opening Stud
Errington, F. A., 39 Cortlandt St., N. Y. City.

Slotting Machines
Armstrong Bros. Tool Co., 315 N. Francisco Ave., Chicago, Ill.
Baker Bros., Toledo, Ohio.
Betts Machine Co., Wilmington, Del.
Garvin Mach. Co., Spring and Varick St., N. Y. C.
Newton Machine Tool Works, 23rd and Vine St. Philadelphia, Penn.
Niles-Bement-Pond Co., 111 Broadway, N. Y. C.
Sellers & Co., Inc., Wm., Philadelphia, Penn.

Soap, Hand
White & Bagley Co., Worcester, Mass.
"Cleanzum."

Sockets and Sleeves
Cleveland Twist Drill Co., E. 49th St. and Lakeside Ave., Cleveland, Ohio.
Morse Twist Drill & Mach. Co., New Bedford, Mass.
Pratt & Whitney Co., Hartford, Conn.
Standard Tool Co., Cleveland, Ohio.
Whitman & Barnes Mfg. Co., Akron, Ohio.

Special Machinery and Tools
Atlantic Motor & Supply Co., West Somerville, Mass.
Becker Milling Mach. Co., Hyde Park, Mass.
Bicknell-Thomas Co., Greenfield, Mass.
Bilgram Machine Works, 1233 Spring Garden St., Philadelphia, Penn.
Blanchard Machine Co., 64 State St., Cambridge, Mass.
Cambridge Machine Co., Cambridge, Ohio.
Carroll Engineering Co., The, Dayton, Ohio.
Coats Mach. Tool Co., Inc., 30 Church St., N. Y. C.
Columbus Die Tool & Mach. Co., Columbus, Ohio.
Cowdrey Mach. Wks., C. H., Fitchburg, Mass.
Crane Puller Co., 54 Lake St., Arlington, Mass.
Dexter Co., I. H., 27 Walker St., New York.
Earle Gear & Machine Co., 101 E. Wyoming Ave., Philadelphia, Penn.
Fawcus Machine Co., Pittsburgh, Penn.
Fenn Mfg. Co., Hartford, Conn.
Fischer Machine Co., Philadelphia, Penn.
Foster Machine Co., Elkhart, Ind.
Gardam & Sons, Wm, 108-114 Park Pl., N. Y. C.
Garvin Mach. Co., Spring and Varick St., N. Y.C.
Gem City Machine Co., Dayton, Ohio.
Genesee Precision Tool & Die Co., Rochester, N.Y.
Grayson Tool & Mfg. Co., Indianapolis, Ind.
Harris Eng. Co., The H. E., Bridgeport, Conn.
Hartford Special Machinery Co., The, 287 Homestead Ave., Hartford, Conn.
Hoefer Mfg. Co., Freeport, Ill.
Holyoke Machine Co., Worcester, Mass.
International Oxygen Co., 115 Broadway, N. Y.
Krasberg Mfg. Co., 410-420 Orleans St., Chicago, Ill.
Langelier Mfg. Co., Providence, R. I.
Luster-Jordan Co., Norristown, Penn.
Mallometer Co., Detroit, Mich.
Marvin & Casler Co., Canastota, N. Y.
Mehl Mach. Tool & Die Co., Roselle, N. J.
Designers and builders of watch, clock, typewriter, adding machines and the like. New shop, new machinery, accurate, competent, expert machinists.
Meisel Press Mfg. Co., 946 Dor. Ave., Boston.
Modern Tool Die & Mach. Co., Columbus, Ohio.
Nazel Engineering & Machine Works, 4039 N 5th St., Philadelphia, Penn.
New England Mchy. Co., Stiles St., New Haven, Conn.
Newton Machine Tool Works, 23rd and Vine St., Philadelphia, Penn.
Oxweld Acetylene Co., Chicago, Ill.
Peerless Machine Co., 1615 Racine St., Racine, Wis.
Reynolds Pattern & Machine Co., Moline, Ill.
Rowbottom Machine Co., Waterbury, Conn.
Sanford Mfg. Co., F. C., Bridgeport, Conn.
Sheffield Mach. & Tool Co., The, Dayton, Ohio.
Simonds Mfg. Co., Pittsburgh, Penn.
Sloan & Chace Mfg. Co., Newark, N. J.
Stecher Co., The Chas., 1576 Crossing St., Chicago.
Steel Products Engineering Co., Springfield, Ohio.
Stevens Mfg. Co., Dayton, Ohio.
Taft-Peirce Mfg. Co., Woonsocket, R. I.
Underwood & Co., H. B., 1026 Hamilton St., Philadelphia, Penn.
Waltham Machine Wks., High St., Waltham, Mass.

Springs
Barnes Co., Wallace, 38 Wallace St., Bristol, Conn.

Sprockets and Chains
American Chain Co., Bridgeport, Conn.
Baldwin Chain & Mfg. Co., Worcester, Mass.
All American sizes both roller and block.
Bilgram Machine Works, 1233 Spring Garden St., Philadelphia, Penn.
Boston Gear Works, Norfolk Downs, Mass.
Caldwell & Son Co., H. W., 17th St. and Western Ave., Chicago, Ill.
Grant Gear Works, Inc., 151 Pearl St., Boston.
Link-Belt Co., 39th St. and Stewart Ave., Chicago, Ill. Philadelphia and Indianapolis.
Morse Chain Co., Ithaca, N. Y.
Philadelphia Gear Works, Vine St. and Reading R.R., Philadelphia, Penn.
Whitney Mfg. Co., The, Hartford, Conn., U. S. A.
Sprockets for chains of silent type. Three types of chains—roller, block and silent, in various American sizes.

Squares
Starrett Co., L. S., Athol, Mass.

Stampings, Metal
American Tube & Stamping Co., Bridgeport, Conn.
Bay State Stamping Co., Worcester, Mass.
Blum & Co., Julius, 510-512 W. 24th St., N. Y. C.
Gem Mfg. Co., 3257 Spruce St., Pittsburgh, Penn.
Geuder, Paeschke & Frey Co., 1301 St. Paul Ave., Milwaukee, Wis.
Kales-Haskel Co., Detroit, Mich.
Krasberg Mfg. Co., 410-420 Orleans St., Chicago, Ill.
New Britain Machine Co., New Britain, Conn.

Stampings, Welded
Standard Welding Co., W. 76th St., Cleveland, O.
Branches: Ford Bldg., Detroit; U. S. Express Bldg., New York City; Peoples Gas Bldg., Chicago; Merchants Bank Bldg., Indianapolis. Cable: Stanweld.

Stamps, Steel
Hoggson & Pettis Mfg. Co., The, New Haven, Conn., U. S. A.
Hand cut steel stamps, letters and figures; also marking machine rolls and machine stamps.
Keller Mechanical Engraving Co., Brooklyn, N. Y.
Agents: England, France, Italy, Alfred Herbert, Ltd.
Matthews & Co., Jas. H., Pittsburgh, Penn.
Schwerdtle Stamp Co., 39 Canal St., Bridgeport, Conn.
Schoder & Lombard S. & D. Co., 251 Canal, N. Y.

Stands, Portable (See Furniture, Machine Shop)

Steam Specialties
Dart Mfg. Co., E. M., Providence, R. I.
Reliance Gauge Column Co., 6009 Carnegie Ave., Cleveland, Ohio.

Steel, Cold and Hot Rolled Sheet
American Tube & Stamping Co., Bridgeport, Conn.
Blum & Co., Julius, 510-512 W. 24th St., N. Y. C.
Century Steel Co., Equitable Bldg., N. Y. C.

Steel Hardness Measuring Instruments
Shore Instrument & Mfg. Co., 555 W. 22nd St., New York City. "Sceleroscope."

Steel Heat Testing Instruments
Shore Instrument & Mfg. Co., 555 W. 22nd St., New York. "Pyroscope."

Steel, Shafting and Free Cutting Screw
Blum & Co., Julius, 510-512 W. 24th St., N. Y. C.

Steel, Sheet
Century Steel Co., Equitable Bldg., N. Y. C.
Hobson, Houghton & Co., 83 Beekman St., N. Y. C.
Jessop & Sons, Inc., Wm., 91 John St., N. Y. C.
Moltrup Steel Products Co., Beaver Falls, Penn.

Union Drawn Steel Co., Beaver Falls, Penn.
Vanadium Alloys Steel Co., Pittsburgh, Penn.
Vulcan Crucible Steel Co., Aliquippa, Penn.
Ward's Sons, Edgar T., 25 Purchase St., Boston.
Western Tool & Mfg. Co., Springfield, Ohio.

Steels, Chrome
Century Steel Co., Equitable Bldg., N. Y. C.
Firth-Sterling Co., McKeesport, Penn.
Halcomb Steel Co., Syracuse, N. Y.
Hawkridge Bros. Co., 303 Congress St., Boston.
Jessop & Sons, Inc., Wm., 91 John St., N. Y. C.
Vanadium Alloys Steel Co., Pittsburgh, Penn.
Vulcan Crucible Steel Co., Aliquippa, Penn.
Williams Co., J. H., 35 Richards St., Brooklyn.

Steels, High-Speed
American Comp. Co., 469 Atlantic Ave., Boston.
Apex Steel Sorp., 50 Church St., New York City.
Armstrong Bros. Tool Co., 315 N. Francisco Ave., Chicago, Ill.
Boker & Co., Inc., H., 101 Duane St., N. Y. C.
Century Steel Co., Equitable Bldg., N. Y. C.
Cleveland Twist Drill Co., E. 49th St. and Lakeside Ave., Cleveland, Ohio. New York, 30 Reade St.; Chicago, 9 N. Jefferson St.
Firth-Sterling Steel Co., McKeesport, Penn.
Halcomb Steel Co., Syracuse, N. Y. Branches: Chicago, Cleveland, Philadelphia, New York. Trade-mark "Dreadnought."
Hawkridge Bros. Co., 303 Congress St., Boston
Haynes-Stellite Works, Kokomo, Ind.
Hobson, Houghton & Co., 83 Beekman St., N. Y. C.
Vanadium Alloys Steel Co., Pittsburgh, Penn.
Vulcan Crucible Steel Co., Aliquippa, Penn.
"Vulcan-Cobalt" for turning shells.
Ward's Sons, Edgar T., 25 Purchase St., Boston.
Williams Co., J. H., 35 Richards St., Brooklyn.

Stocks, Die (See Taps and Dies)

Stools, Shop
Manufacturing Equipment & Engineering Co., 209 Washington St., Boston, Mass.
New Britain Machine Co., New Britain, Conn.

Straightening Machinery
Crane Puller Co., 54 Lake St., Arlington, Mass.
Langelier Mfg. Co., Providence, R. I.
Morse Twist Drill & Mach. Co., New Bedford, Mass.
Shuster Co., The F. B., New Haven, Conn.
75 sizes. 1" and smaller, various shapes.
Springfield Machine Tool Co., Springfield, Ohio.
Cable: Montanus.
Bench straightening press, 3 sizes.

Swaging Machines
Excelsior Needle Co., Torrington, Conn. Cable Address: Excelsior.
Sizes—Nos. 00, 1, 2, 3, 3½, tube. Capacities: $\frac{1}{16}$", $\frac{3}{32}$", $\frac{3}{16}$", ⅜", ¾", 2", 1⅝". 30 lb., $100; 100 lb., $200; 500 lb., $350; 850 lb., $450; 1,750 lb., $550; 2,450 lb., $600; 2,100 lb., $600.
Taper, point and reduce all kinds of solid and tubular or hollow metals.
Agents: Coventry Swagging Co., Ltd., White Friars Lane, Coventry, England; Societe Arronyme des Establissement de Fenwick Freres & Co., 8, Rue de Rocroi, Paris, France.
Langelier Mfg. Co., Providence, R. I.

Switches and Switchboards
C & C Elec. & Mfg. Co.—Garwood, N. J.
General Electric Co., Schenectady, N. Y.
Gerstner & Sons, H., 22 Columbia St., Dayton, O.
Sprague Electric Works, 527 W. 34th St., N. Y. C.
Wagner Electric Mfg. Co., St. Louis, Mo.
Westinghouse Elec. & Mfg. Co., Pittsburgh, Penn.

Tachometers
Bristol Co., Waterbury, Conn.

Tap Extractors, Broken
Walton Co., The, Hartford, Conn.
Sixteen sizes from No. 8 to 1¼" tops.

Tap Holders
Errington, F. A., 39 Cortlandt St., N. Y. City
Greenfield Tap & Die Corp., Greenfield, Mass.
Warner & Swasey Co., Cleveland, Ohio.

Taper Pins
Brown & Sharpe Mfg. Co., Providence, R. I.
Morse Twist Drill & Mach. Co., New Bedford, Mass.
Pratt & Whitney Co., Hartford, Conn.
Standard Tool Co., Cleveland, Ohio.

Tapes, Measuring
Starrett Co., L. S., Athol, Mass.

Tapping Machines and Attachments
Acme Machinery Co, Cleveland, Ohio Cable Address: Acme, Cleveland.
American Tool Works Co., Cincinnati, Ohio.
Baker Bros., Toledo, Ohio.
Beaman & Smith Co., Providence, R. I.
Bicknell-Thomas Co., Greenfield, Mass.
Cincinnati Bickford Tool Co., Oakley, Cincinnati, O
Errington, F. A., 39 Cortlandt St., New York City.
Evans Stamping & Plating Co., Taunton, Mass.
Capacities up to ¼". Hand or foot operated.
Cable Address: "Paragon, Taunton."
Fenn Mfg. Co., Hartford, Conn.
Garvin Mach. Co., Spring and Varick St., N. Y. C
Harris Eng. Co., The H. E., Bridgeport, Conn.
Hoefer Mfg. Co., Freeport, Ill.
Langelier Mfg. Co., Providence, R. I.
Moline Tool Co., Moline, Ill.
Wells & Son Co., F. E., Greenfield, Mass.
Whitney Mfg. Co., The, Hartford, Conn., U. S. A.
Cable Address: "Whitney, Hartford."
"Hollm Patent" friction tapping device. Three

sizes, ¼" to ⅝" taps, ¼" to ⅝" taps, 7/16" to 1¼" taps. This device is interchangeable with our "Presto" chuck.

Taps and Dies
Bay State Tap & Die Co., Mansfield, Mass.
Brubaker & Bros., W. L., Millersburg, Pa. New York, Chicago, Pittsburgh, San Francisco.
Butterfield & Co., Derby Line, Vt.
Card Mfg. Co., S. W., Mansfield, Mass. N. Y. Office: 62 Reade St. Cable: Card, Mansfield. All sizes in V., U. S. standard, S. A. E. standard, A. S. M. E. standard, Whitworth standard, French and International standards (metric system), Lowenherz standard, B. A. standard. Taps—Beaman & Smith, bicycle taper, bit-brace, blacksmith, combined pipe, tap and drill, flexible stay-bolt, harbor masters', jewelers', machine or nut, machine screw, machinists' hand, mud plug, patch bolt, pipe, pipe hob, pulley, small watchmakers'. Dies—Favorite, machine or solid bolt, Paragon, round, adj. pipe, round adjustable, Smith patent adjustable, spring screw threading, solid sq. pipe, die holders. Reed Mfg. Co., Erie, Penn. Pipe or bolt, solid or adjustable, ⅛" to 4".
Saunders Sons, D., Yonkers, N. Y.
Standard Tool Co., Cleveland, Ohio.
Wells & Son Co., F. E., Greenfield, Mass.
Wells Bros. Co., Greenfield, Mass.

Taps, Collapsing
Errington, F. A., 39 Cortlandt St., N. Y. City.
Geometric Tool Co., New Haven, Conn. 545 W. Washington Blvd., Chicago. Cable: Metric. For cutting all classes of internal screw threads above ¾ in.
Manufacturers Equipment Co., Chicago, Ill.
Murchey Mach. & Tool Co., 64 Porter St., Detroit.
Victor Tool Co., Waynesboro, Penn.

Testing Metals and Materials
Souther Engineering Corp., Hy., Hartford, Conn.

Thermometers
Bristol Co., Waterbury, Conn.
Brown Instrument Co., Philadelphia, Penn.

Thread-Cutting Tools
Armstrong Bros. Tool Co., 315 N. Francisco Ave., Chicago, Ill.
Geometric Tool Co., New Haven, Conn.
Greenfield Tap & Die Corp., Greenfield, Mass.
Harris Eng. Co., The, H. E., Bridgeport, Conn.
Jones & Lamson Machine Co., Springfield, Vt.
Krasberg Mfg. Co., 410-420 Orleans St., Chicago, Ill.
Landis Machine Co., Waynesboro, Penn. Sizes ½" to 4".
Murchey Mach. & Tool Co., 64 Porter St., Detroit.
National Machinery Co., Tiffin, Ohio.
Pratt & Whitney Co., Hartford, Conn.
Rivett Lathe & Grinder Co., Brighton, Boston.
Union Caliper Co., Orange, Mass.
Williams Co., J. H., 35 Richards St., Brooklyn.

Tool Chests
Gerstner & Sons, H., 22 Columbia St., Dayton, O. Twenty-eight styles carried in stock. Special cases and chests made to order.
Union Tool Chest Works, Rochester, N. Y.

Tool Holders
Armstrong Bros. Tool Co., 315 N. Francisco Ave., Chicago, Ill.
Celfor Tool Co., Buchanan, Mich.
Pratt & Whitney Co., Hartford, Conn.
Rex Mfg. Co., Hyde Park, Boston, Mass., U. S. A. Rex tool post for multiple spindle and single tool work. Narrow, allowing close setting. Swivels any direction. Fits any lathe by means special T-nut.
Union Caliper Co., Orange, Mass.
Western Tool & Mfg. Co., Springfield, Ohio.
Williams Co., J. H., 35 Richards St., Brooklyn.

Tools, Small (See Machinists' Small Tools)

Torches, Blow
Gem Mfg. Co., 3257 Spruce St., Pittsburgh, Pa.
Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Transformers
Crocker-Wheeler Co., Ampere, N. J.
General Electric Co., Schenectady, N. Y.
Wagner Electric Mfg. Co., St. Louis, Mo.
Westinghouse Elec. & Mfg. Co., Pittsburgh, Penn.

Transmission Machinery
American Pulley Co., 29th and Bristol, Phila., Pa. 33 Greene St., N. Y. City; 124 S. Clinton St., Chicago; 165 Pearl St., Boston; 536 First Ave., S., Seattle. Cable: Amerpulley.
Caldwell Co., Inc., W. E., Louisville, Ky.
Holyoke Machine Co., Worcester, Mass.
Link-Belt Co., 39th St. and Stewart Ave., Chicago, Ill. Philadelphia and Indianapolis.
O. K. Clutch & Mchy. Co., Columbia, Penn.
Rockwood Mfg. Co., The, Indianapolis, Ind.

Traps, Steam
American Blower Co., 1400 Russell St., Detroit.
Houghton & Co., E. F., 240 W. Somerset St., Philadelphia, Penn.
Reliance Gauge Column Co., 6009 Carnegie Ave., Cleveland, Ohio.

Trolleys and Tramways
Chisholm-Moore Mfg. Co., Cleveland, Ohio.
Harrington, Son & Co., Inc., Ed., Philadelphia, Pa.
Wright Mfg. Co., Lisbon, Ohio.

Trucks
Clark Co., Geo. P., Windsor Locks, Conn. Two sizes, capacity 1,000 lb.; 4 sizes, capacity 2,200 lb. Elevating, hand and special trucks made to order.
Cowan Truck Co., Holyoke, Mass., U. S. A. Cable Address: "Cowantruck," Holyoke. Complete line of hand and electric elevating trucks ranging in price from \$60 to \$1,800 to handle loads from 1,500 to 5,000 lb. Send for catalog.
General Electric Co., Schenectady, N. Y.
National Scale Co., Montgomery St., Chicopee Falls, Mass. "National-Chapman" elevating trucks, 15 models, including combination scale elevating trucks. Capacities 2,500 to 4,000 lb.
New Britain Machine Co., 20 Chestnut St., New Britain, Conn. 2008 W. Grand Blvd., Detroit.

Tube Mill Machinery, Seamless and Welded
Standard Engineering Co., Ellwood City, Penn.

Tubing, Flexible
Almond, T. R., 6 Maple Ave., Ashburnham, Mass.

Tubing, Seamless Steel and Brass and Copper
Blum & Co., Julius, 510 W. 24th St., N. Y. City.
Elyria Iron & Steel Co., E. 131st St., Cleveland, O.
Murcott-Duden Co., 253 Broadway, N. Y. C.
Standard Welding Co., W. 76th St., Cleveland, O. Branches: Ford Bldg., Detroit; U. S. Express Bldg., New York City; Peoples Gas Bldg., Chicago; Merchants Bank Bldg., Indianapolis. Cable: Stanweld. Electrical welded. Made by the electric welding process.
Ward's Sons, Edgar T., 25 Purchase St., Boston.

Turntables
Canton Foundry & Mach. Co., Canton, Ohio.
Link-Belt Co., 39th St. and Stewart Ave., Chicago, Ill. Philadelphia and Indianapolis.

Turret Heads
Almond, T. R., 6 Maple Ave., Ashburnham, Mass.

Turrets, Tool Post
American Tool Wks. Co., Cincinnati, Ohio. Cable: Lathes, Cincinnati. For application to any standard make of lathe. Turret holes, rough bored to be finished by customers after turret has been mounted on lathe. Templet of lathe bed or crossbridge required.
Newman Mfg. Co., 717 Sycamore St., Cincinnati, Ohio. Can be attached to any ordinary lathe, screw machine or turret machine; also manufacturing a tailstock turret for any lathe for drilling, reaming, boring, tapping, etc.
Phoenix Mfg. Co., Eau Claire, Wis.

Unions, Pipe
Dart Mfg. Co., E. M., Providence, R. I.

Universal Joints
Baush Machine Tool Co., 604 Wason Ave., Springfield, Mass., U. S. A.
Boston Gear Works, Norfolk Downs, Mass.
Gray & Prior Mach. Co., Hartford, Conn.
Mutual Mach. Co., 27 Wells St., Hartford, Conn.

Valves
Elmes, Chas. F., 1001 Fulton St., Chicago, Ill.

The Power of the MAGNETIC CHUCK

There was a time when folks were "leary" of Magnetic Chucks but that was long ago.

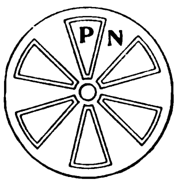
It's a "Safe Bet" that on your particular job a Walker Magnetic Chuck wlll split the costs.

No wonder they're growing more popular every day.

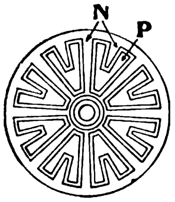
You don't need a special outfit for every new job. One Walker Magnetic Chuck will serve for any number of odd sized and odd shaped pieces.

Today is Catalog Day

Why not write for yours.



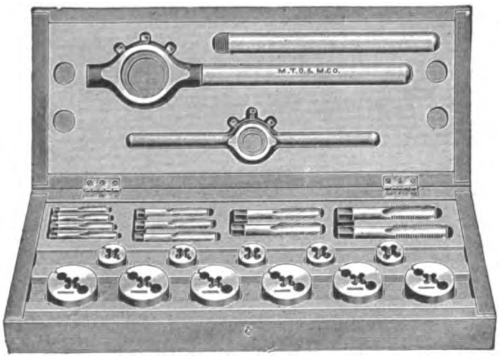
Standard Type



Multi-tooth Type

O. S. Walker Co. Successors To O. S. Walker & Co. Walker Grinder Co. **Worcester, Mass.**

A SET OF ROUND DIES



complete with holders, taps and wrenches is a valuable part of any shop equipment and especially so when the dies have the thread cutting ability possessed by "Morse" dies. They are accurately cut and relieved to reproduce threads that are clean and true to size.

Carried in stock in both adjustable and solid type in "V", U. S. S. and S. A. E. threads.

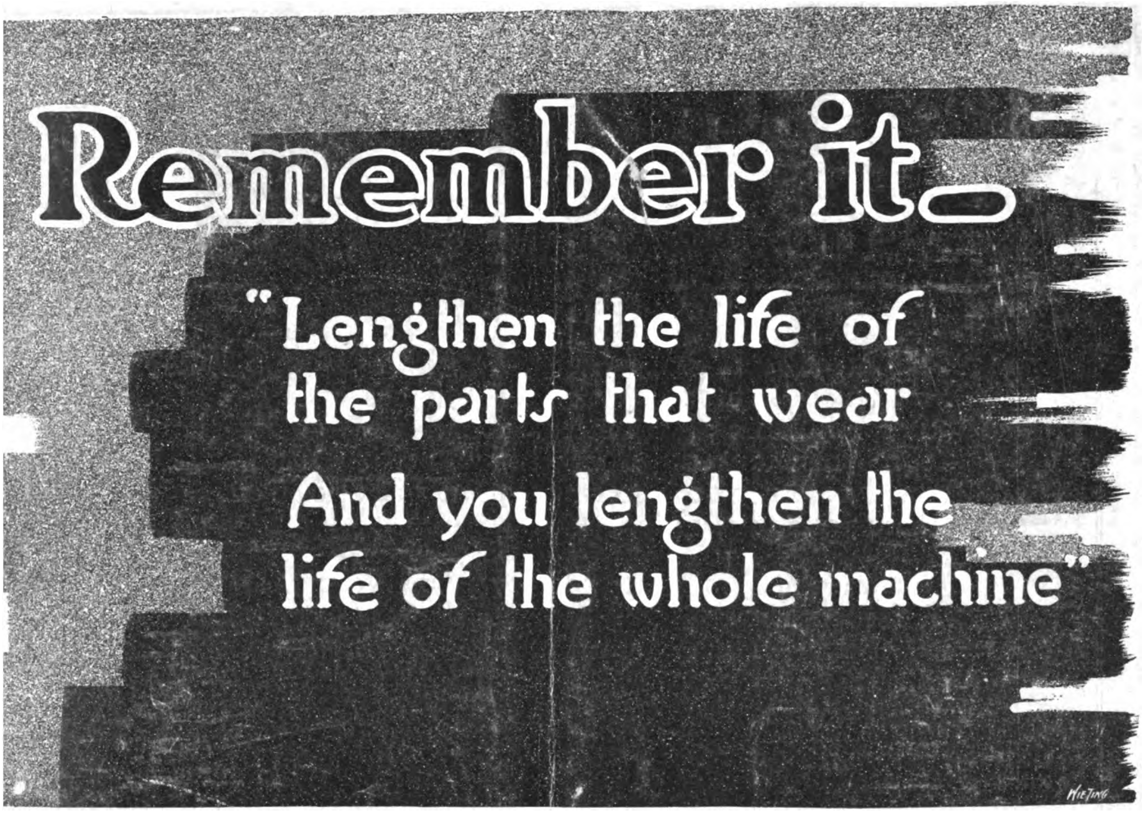
Union Caliper Co., Orange, Mass.
Wells Bros. Co., Greenfield, Mass.

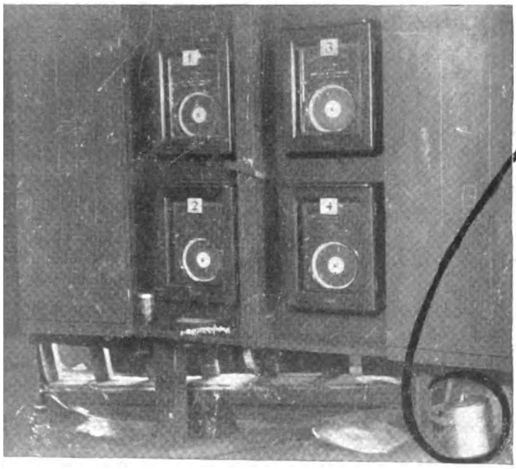
YEARS AGO—and not many at that—it was considered high treason and the limit of folly to *say* anything in an advertisement. Now nearly every advertisement has something to say—a different something every issue. You may have looked up an article in the *Buyers Cyclopedia* last week and found nothing in the ad that interested you. Try it again this week—ten to one there is a new story throwing new light from a new angle. This *Buyers Cyclopedia* is an epitome of what's in the buying section. Consult it as you would an index to your favorite author.

To be here is a badge of responsibility.
To buy from here is a guarantee of satisfaction.

LINDE A.P.CO.
LINDE OXYGEN
PRIVATE OXYGEN PLANT
Abnormal Business Conditions—
What We Are Doing To Meet Them
Chapter G.
Demonstrating That a Single Plant Service Cannot Compete With a Forty-Stations Service.
Linde success in meeting the tests imposed by abnormal conditions, has completely exposed the weakness of private plant service.
These private plants many of which have already fallen by the wayside, were installed on the theory that they would prove economical and dependable.
In actual practice the fallacy of the theory has been thoroughly exposed by balance sheet comparisons—comparisons of the cost of operation and the actual service rendered by these two competing sources of supply.
Among the factors contributing to the failure of the private plant, in all these cases are the following:
—Unlooked for increases in Oxygen consumption—far beyond the capacity of single plant service.
—Unlooked for operating trouble—involving temporary failure of supply and expensive repairs.
—Unlooked for operating expenses—upsetting manufacturing estimates.
—Unlooked for deterioration—upsetting investment calculations.
—And last, but not least, the extension of Linde Service through new factories and warehouses to provide a nearer and more convenient source of supply for each district.
These are but a few of the factors that have brought about the discontinuance of many private plants, by concerns who have written off their investments to place their dependence in Linde Oxygen exclusively.
In maintaining this service to these users, the Linde Company often finds it necessary to "shift the load" from one of its distributing stations to another—to meet suddenly increased and widely fluctuating demands.
This is service which the Linde Company alone can render—service made possible through the Company's chain of 40 distributing stations backed by its enormous manufacturing facilities.
In Chapter "H" we will comment on the service rendered to the Oxy-Acetylene Industry as a whole, by our staff of experts and engineers.
The Linde Air Products Company
42nd Street Bldg., New York City, N. Y.
"Largest Producers of Oxygen in the World"

INDEX TO AMERICAN ADVERTISERS





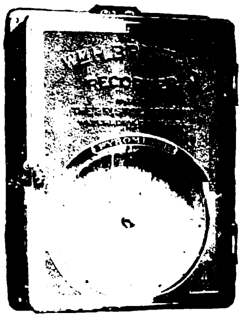
Jim Smith owns this pail

Jim Smith, operator, is dependent upon the two things shown in this picture; his dinner pail and his Bristol's Electric Pyrometers. Both supply a vital need. Jim relies upon them both for securing greater efficiency; they are necessities to himself and to his work.

TRADE MARK
BRISTOL'S
REG. U. S. PAT. OFFICE.

Electric Pyrometers

are rugged instruments of remarkable simplicity of design, requiring the minimum amount of attention.



The modern heat treatment of steel requires the use of Pyrometers. And to secure the greatest durability and most accurate results with the greatest ease requires the use of Bristol's Pyrometers.

Remember, Bristol's is the only Pyrometer equipped with the high-grade Weston movement, known and recognized the world over.
